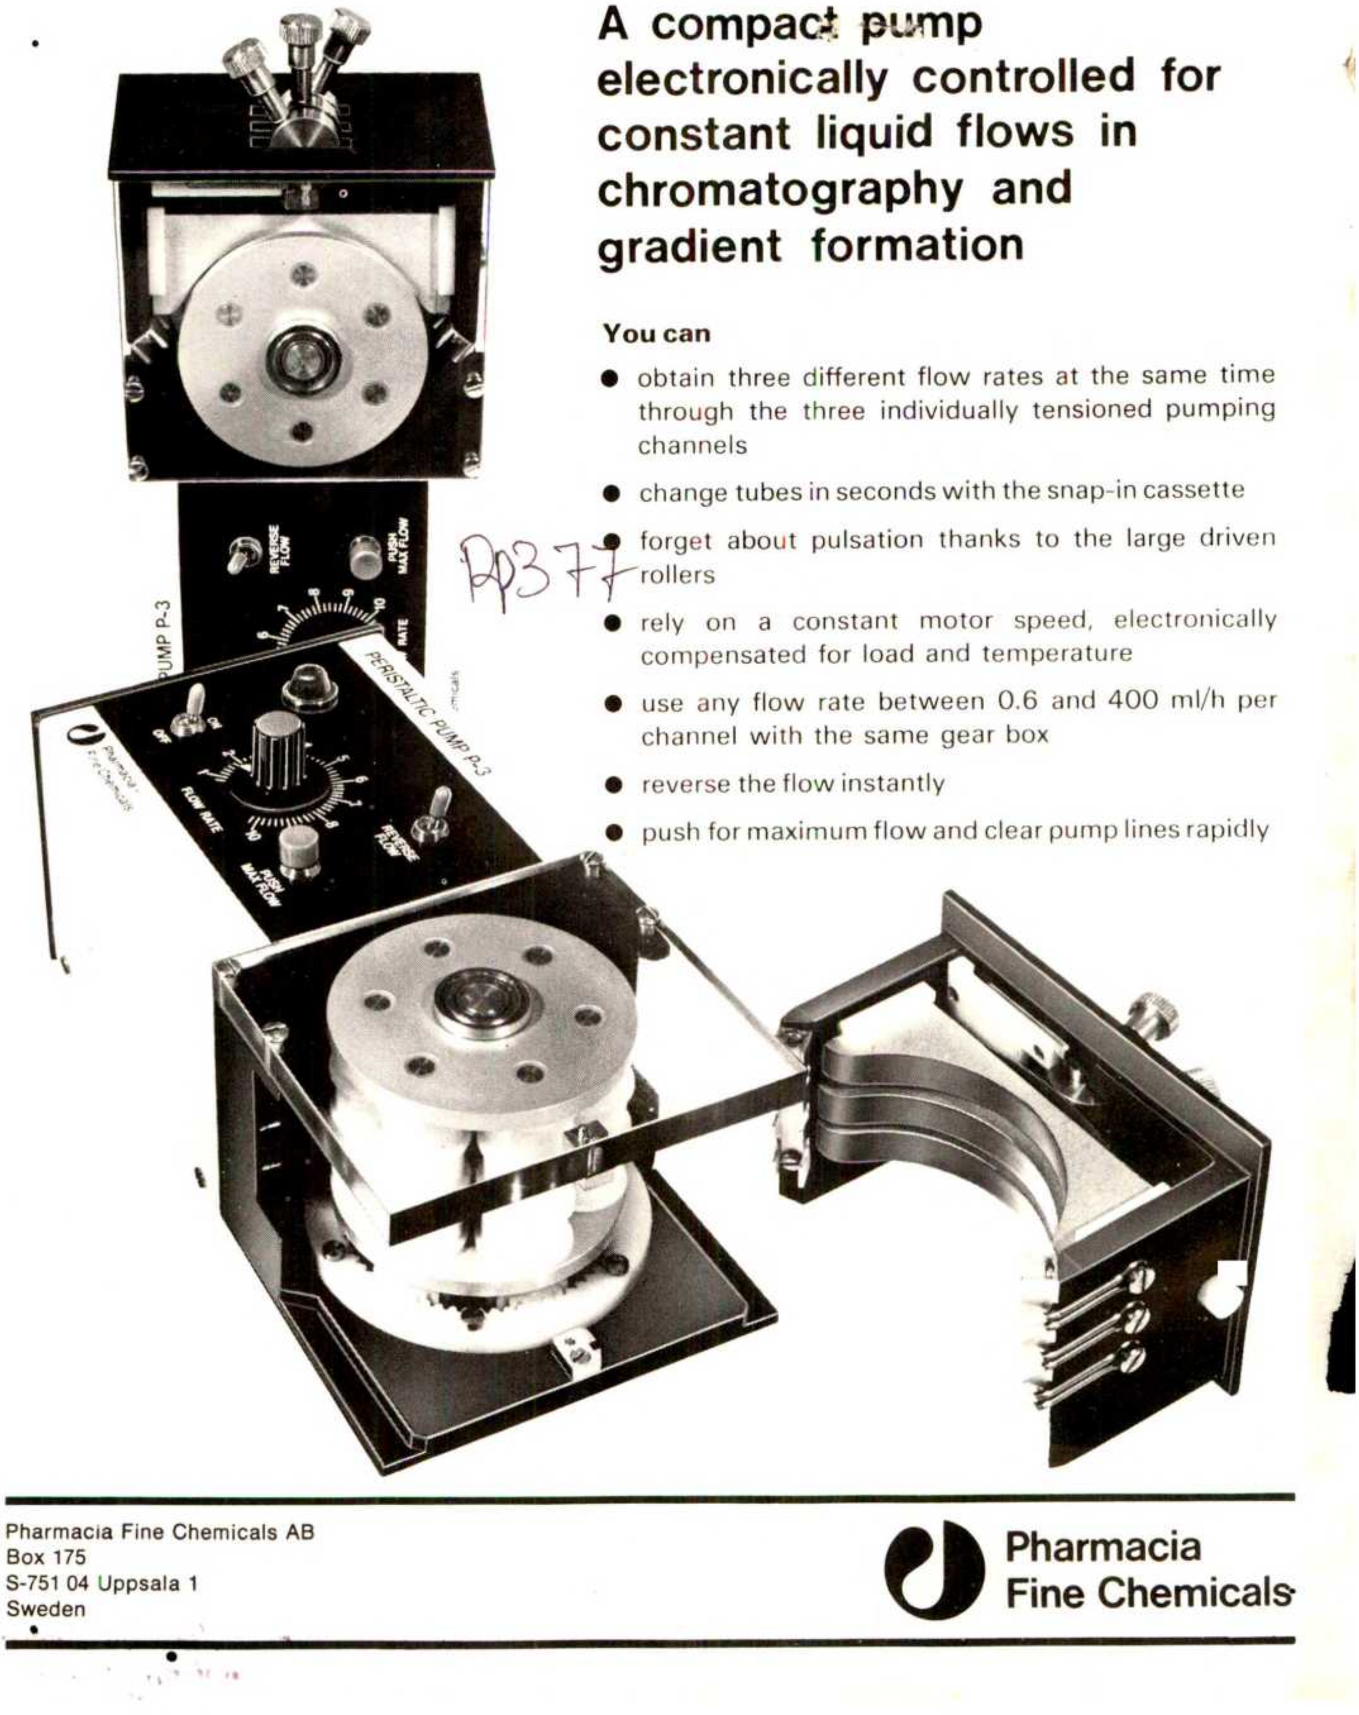
Pharmacia Peristaltic Pump P-3



A compact pump electronically controlled for constant liquid flows in chromatography and gradient formation

You can

- obtain three different flow rates at the same time through the three individually tensioned pumping channels
- change tubes in seconds with the snap-in cassette
- forget about pulsation thanks to the large driven rollers
- rely on a constant motor speed, electronically compensated for load and temperature
- use any flow rate between 0.6 and 400 ml/h per channel with the same gear box
- reverse the flow instantly
- push for maximum flow and clear pump lines rapidly

[illegible]
SCIENCE COLLEGE

Guide to authors

Nature accepts three types of communications

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words, at most they have three or four displayed items (figures and tables)
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature* A limit of 300 words is placed on contributions in this category

Manuscripts may be submitted either to London or Washington Three typed copies should be submitted, each including lettered copies of figures Typing (including references) should be double spaced The title should be brief and informative Pages should be numbered References, tables and figure legends should start on separate pages Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends Units should conform to the Systeme International Greek characters should be identified in the margin on their first appearance Equations should occupy single lines if possible exp (a) is preferred to e^a if 'a' is more than one character Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn

References are indicated by superscripts in the text The style may be gleaned from any contemporary *Nature* with the following two changes

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given

(ii) The last page as well as the first of any reference should be cited

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed (Butterworth, 1963-65) Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references Their publisher and place of publication should be clearly indicated 'Personal communication' and 'unpublished work' should be incorporated in the text

Artwork should be sent with the manuscript All artwork should be marked with the author's name Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable, thin, shiny, folded, torn or heavily handled material should be avoided Matt rather than glossy photographs are preferred Figures are usually reduced to one column width The originals should be about as wide as a page of *Nature* Figures, particularly maps, should contain nothing but essential material It is preferred that the original be unlabelled, but with a copy containing lettering Labelling on photographs should if possible be avoided entirely

A fuller guide appeared in *Nature* (**246**, 238, 1973)

Differential staining of human and mouse chromosomes in interspecific cell hybrids—*M Bobrow and J Cross* 77

T lymphoblastoid cell lines from Marek's disease lymphomas—*P C Powell, L N Payne, J A Frazier and M Rennie* 79

Nature for £15

See page xxiv for details of the U.K. personal subscription scheme.

A hundred years ago

We are glad to see that a contemporary not specially devoted to science—the *Morning Post*—in an article on Dr. Hooker's address at Belfast, points out to its readers that the majority of the observations referred to could be made "by any intelligent person without any scientific training," and expresses a hope that "people who have the opportunities for cultivating, and leisure for observing, will make collections of plants . . . . and add to our stock of knowledge." At the same time it suggested these as interesting subjects for observation :—" How much can plants eat in twenty-four hours? When do they eat most? Under what conditions of weather? &c. Indeed, the whole field is one that is almost unexplored." May this hint, which will reach many who are not readers of scientific papers, not be without result! We would draw attention to the fact that plants of *Drosera rotundifolia* are advertised for sale at ninepence each, and we hope that before long some enterprising dealer may make a speciality of all known carnivorous plants for suitable observations.

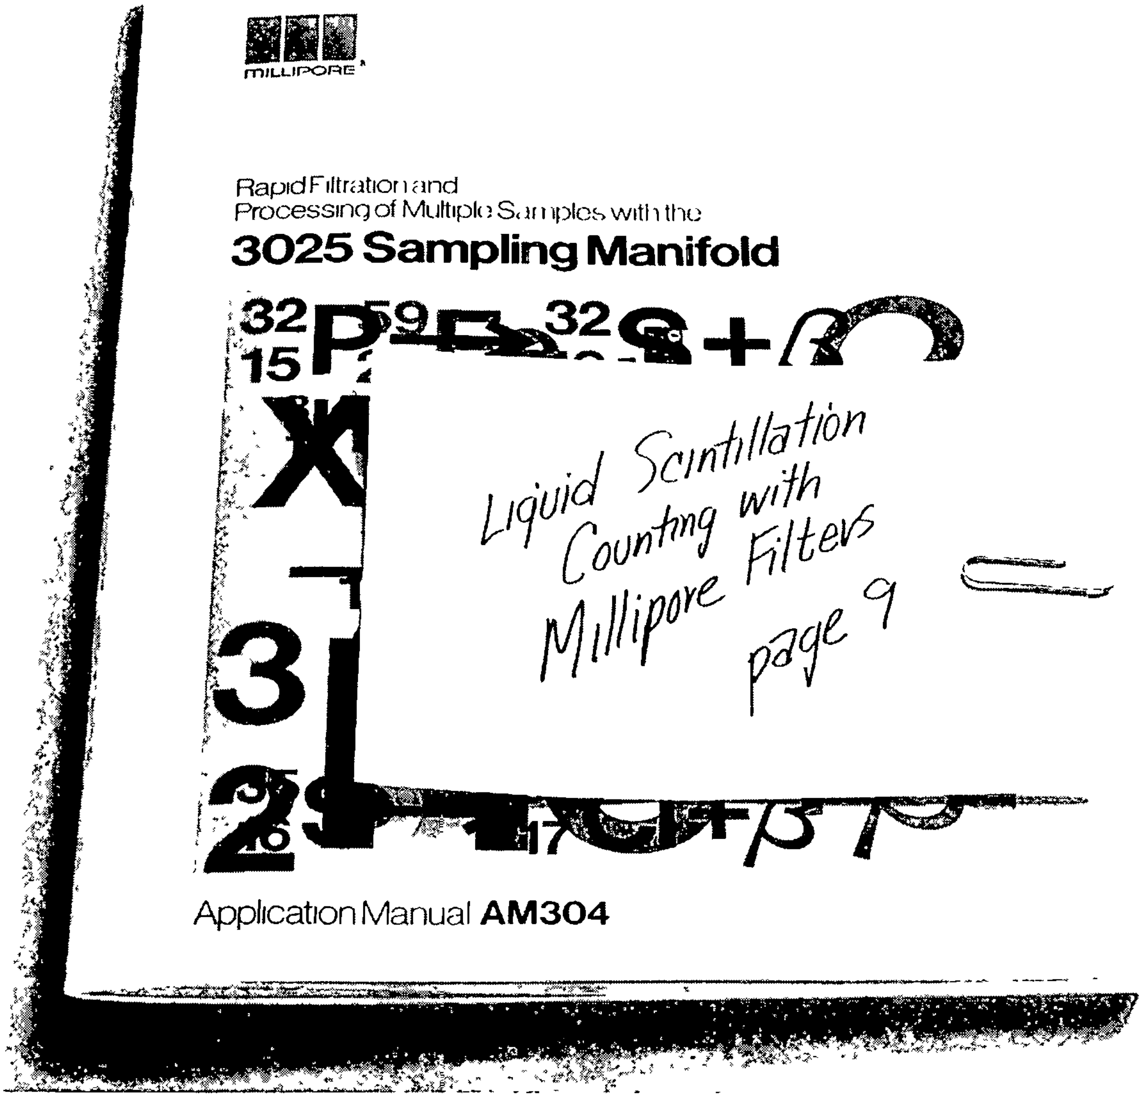
Filtration for the biological scientist

This useful manual describes the basics of sample preparation using various Millipore filters with common LSC cocktails The properties of Millipore filters in protein and nucleic acid binding studies are also described, along with filtration for microbiological sampling and separation, microchemical analysis, and radio tracer ultracleaning.

In all, there are 32 pages of information. Free Ask for Manual AM 304.



MILLIPORE

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 300 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Rifampicin-resistant replication of coliphage N4 DNA—*G. C. Schito, M. Giraldi and M. Toni* 340

Poly(C) in animal viral RNAs—*F. Brown, J. Newman, J. Stott, A. Porter, D. Frisby, C. Newton, N. Carey and P. Fellner* 342

Quantitative cell information quickly and accurately:

THE BARR & STROUD GN5 Integrating Microdensitometer

Improved image analysis techniques give fast scans of only 4 seconds duration with 0.25 micron resolution in the GN5 Integrating Microdensitometer. For accurate histochemical and cytochemical studies of your cell preparations this new instrument offers an accuracy better than ± 1% over an optical density range from less than 0.1 to greater than 2.5. Area measurement, electronic masking and narrowband illumination are some of the features which make this instrument particularly suited to your laboratory. The Barr & Stroud GN5 gives quantitative cell information fast and accurately. It is compact, reliable and ergonomically designed for easy operation.

BIOLOGICAL APPLICATIONS OF LIQUID SCINTILLATION COUNTING

by YUTAKA KOBAYASHI and DAVID V MAUDSLEY

Here is perhaps the only current book devoted to the biological applications of liquid scintillation counting which is not a multi-authored symposium volume, rather, it is a practical textbook, treating all aspects of liquid scintillation counting, including evaluation of instrument performance, preparation of samples, and the application of radioisotopes in biological research In a concise and orderly manner, the book covers the concepts basic to the design of a liquid scintillation counter It thoroughly discusses the principles of radioisotopic analysis, including isotope dilution analysis, double-isotope counting, radioimmunoassays and radio-enzymatic assays

1974, about 204 pp , in preparation

Q MACHINES

by ROBERT W MOTLEY

A Volume in the PURE AND APPLIED PHYSICS Series

Many fundamental experiments in plasma physics have been performed in the Q machine—a device in which highly ionized magnetically-confined plasma is created by contact ionization of atoms and thermionic emission of electrons This monograph—by one of the foremost researchers in the field—presents a coherent account of these experiments and the theory underlying them Topics discussed in detail include the physics and engineering considerations in fabricating the device, the research possibilities afforded by different types of Q machines, the methods by which the basic plasma parameters can be measured, the effects of plasma inhomogeneities on plasma stability, the numerous factors affecting plasma confinement, and an extensive treatment of plasma waves

1974, 185 pp , $15 00/£7 20

HUMAN RESPONSES TO ENVIRONMENTAL ODORS

edited by AMOS TURK, JAMES W JOHNSTON, Jr, and DAVID G MOULTON

The many distinguished researchers who have prepared this book have sampled literally hundreds of odors—not necessarily with their noses, but with the latest and most sophisticated methods of instrumental analysis More important, they have presented an in-depth assessment of individual and community responses to odors, bringing together some of the more recent approaches to the study of olfactory pollution. The book examines among other topics sensory evaluation of odor sources, the transport, dispersal, and possible chemical reactions of odorants in the atmosphere, the assessment of odor intensity, odor annoyance, the odor preferences, and the relationships between odorant properties and the phenomena of odor enchantment and suppression

1974, 366 pp , $19 50/£9 35

SYMMETRY OF MANY-ELECTRON SYSTEM

by I G KAPLAN
translated by J GARRAT

This book describes the application of group-theoretical methods to quantal calculations on many-electron atoms and molecules. It emphasizes the use of group theory in the calculation and classification of molecular states (No previous knowledge of group theory is necessary — though an acquaintance with basic quantum mechanics is assumed) In this book, the method is suitable for applications to molecular systems The book explains the fractional parentage method It describes the use of co-ordinate (or spatial) wave functions when dealing with spin-independent interactions, with several examples showing the utility of the method in quantum chemistry It also features an extensive discussion of the theory of the irreducible representations of the permutation group In addition, it discusses continuous groups, the three-dimensional rotation group, tensor representations and tensor operators—and particularly, the connection between linear and permutation groups, the reduction of tensor representations to irreducible components, and Littlewood's theorem The appendices contain large numbers of tables useful in actual calculations

1975, 384 pp , $34 50/£16 50

ARTIFICIAL INTELLIGENCE

by EARL HUNT

A Volume in the COGNITION AND PERCEPTION Series

This book provides a detailed, unified discussion of the fundamental approaches to the problems of artificial intelligence The author believes that artificial intelligence is based on certain well-understood concepts in applied mathematics, statistics, mathematical logic, and psychology—and that an attack on the unsolved conceptual problems in these areas is of more value than studies of the latest robots or machine chess players Topics covered in detail include pattern recognition, deductive problem solving, theorem proving, perception of the physical world (vision and speech) by machine, and comprehension of natural language The book stresses throughout ways in which basic concepts may be applied to the specific algorithms and programming concepts for these applications

1974, in preparation

PRIMATE AGGRESSION, TERRITORIALITY, AND XENOPHOBIA

A Comparative Perspective

edited by RALPH L HOLLOWAY

This book is a truly wide-ranging comparative account of primate aggression It covers the aggressive behaviour of all primate families—from tree shrews to man—and incorporates not only social, behavioural, and physiological (i e , endocrinological and neurological) data, but also the broader ecological and evolutionary approaches Each contributor is active in research in this field, and each fully develops his own particular viewpoint rather than attempting an artificial "synthesis" of the whole field

1974, 524 pp , $29 50/£14 15

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 300 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

- A fuller guide appeared in *Nature* (**246**, 238; 1973).

TRH potentiates behavioural changes following increased brain 5-hydroxytryptamine accumulation in rats—*A. R. Green and D. G. Grahame-Smith* 524
γ-Aminobutyric acid synthesised in the olfactory nerve—*R. Roskoski, jun., L. D. Ryan and F. J. D. Diecke* 526
Regulation of striatal acetylcholine concentration by dopamine receptors—*V. H. Sethy and M. H. Van Woert* 529

MILES IS SPECIFIC

PEROXIDASE CONJUGATED IgG FRACTIONS: Antisera to Goat IgG, Human IgG, Human IgA, Human IgE, Human IgM, Rabbit IgG (Liquid)
FITC CONJUGATED IgG FRACTIONS: Antisera to Human IgA, Human IgE, Human IgG, Human IgM, Human Fibrinogen
FITC IgG FRACTIONS: Antisera to Bovine, Dog, Guinea Pig, Hamster, Horse, Human, Mouse, Porcine, Rabbit, Rat (Lyophilized & Liquid)
ANTI-STEROIDAL ANTIBODIES: Estriol-6, Estradiol-6, Progesterone-11, Testosterone-7, Androstenedione-7, Estradiol-17
ANTI BOVINE: IgG, IgA & IgM Quantitative Kits

Our continuing program of bringing you new as well as routine use products is illustrated in our catalog. Listed are over 150 different antisera, immunodiffusion plates, immunochemical kits and immunoadsorbents. For a complete catalog or if there is an immunochemical application or problem that requires specific assistance, call or write the office nearest you:

Cover Picture

A hundred years ago *Nature* was reviewing E J Marey's *Animal Mechanism* (page 518, October 29, 1874) These cumbersome mechanisms were soon to be replaced by Muybridge's zoopraxiscope camera On page 567 we look at a Muybridge sequence and—a century later—what happens when the light is switched on

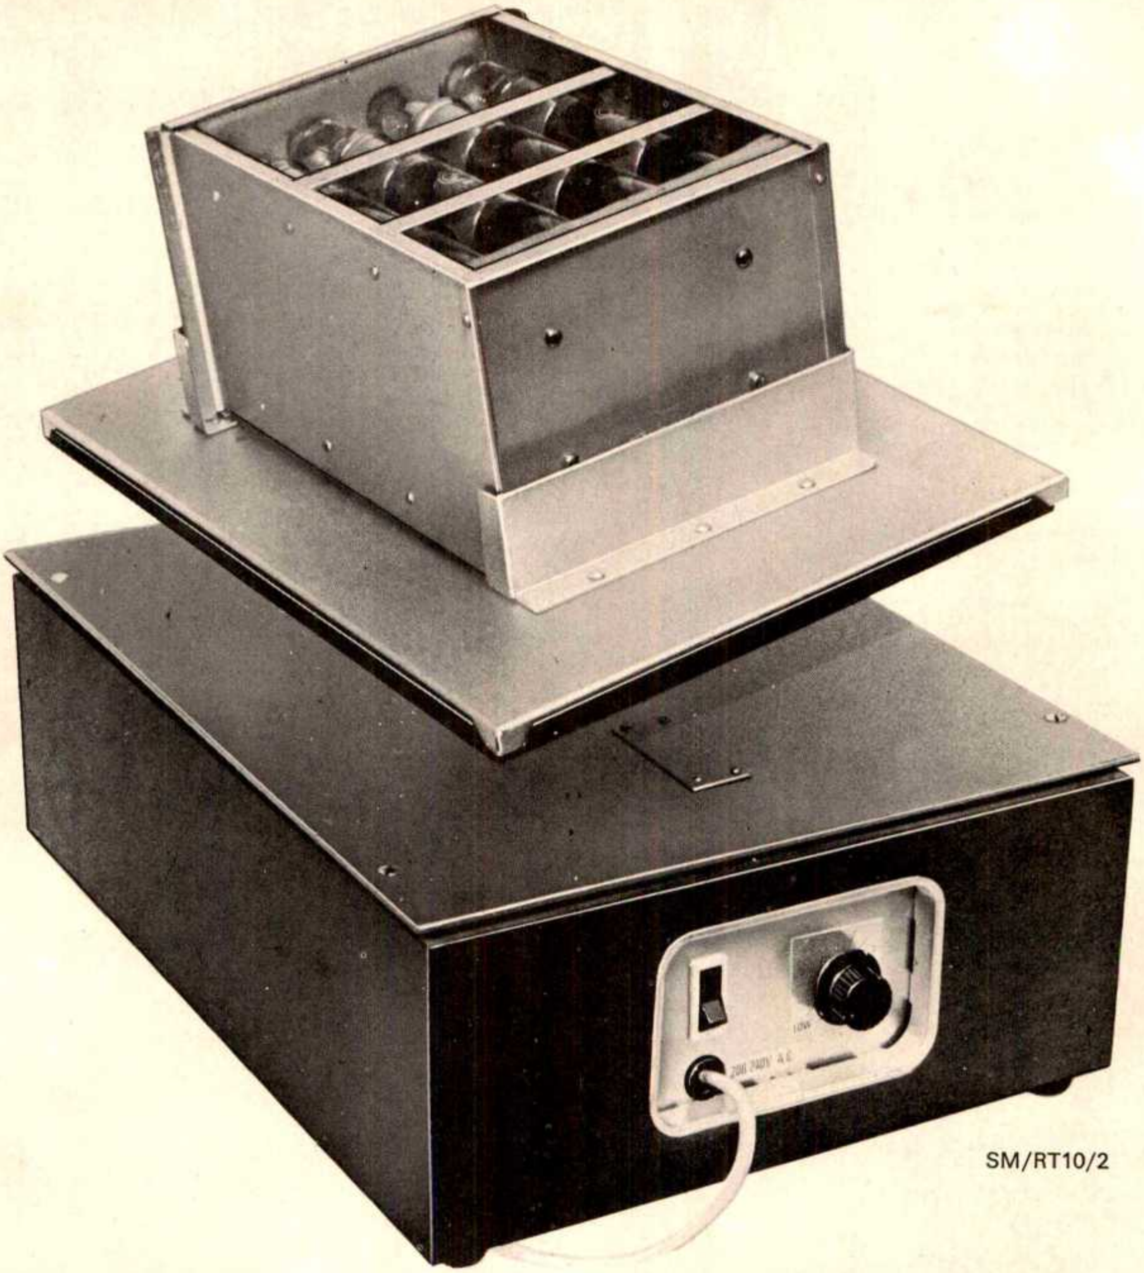
THE NEW SUSPENSION MIXER



SM/RT10/2

The new improved Suspension Mixer provides a unique tilting-rotary action, with a variable angle of tilt from 1°–15° from the horizontal. Operation is continuous, with a variable speed range from 10–100 r.p.m. A timer up to 60 minutes and audible warning can be incorporated as an optional extra.

The principal applications are in the controlled and standardised mixing of various types of suspensions, for example—the Coombes, V.D.R.L., and many other serological and related techniques. The variable tilting agitation with compound action for agglutination, extraction, washing, staining and photographic developments. This unit is capable of regular and continuous operation in an incubator or incubation room. It is also used in many areas of industry—pure research and Quality Control departments.

The Suspension Mixer will accommodate any one of the 'Rotatest' carrying plates and the GWB/F22 viewing lamp.

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 300 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

- A fuller guide appeared in *Nature* (**246**, 238; 1973).

Does it change weight when you heat it?

Put it into the Stanton Redcroft thermobalance, and see exactly what's happening. For any material that changes weight, during rising or falling temperature, the Stanton TG750 thermobalance gives you a direct plot of weight and temperature on a pen recorder. This technique is called Thermogravimetry (TG).

The TG750 is used for quality control, research and routine work. Its ease of loading, compact furnace design and rapid heating and cooling cycle make the TG750 a versatile instrument for many applications.

In addition, it can also give DTG results. (DTG is shorthand for rate of weight change v temperature. This is very helpful in unravelling tricky weight changes, for example where two reactions are close together).

Polymers

You make a batch of Polymers. Which is going to be the most stable? Run them through the TG750 and you see the answer on the curve. (Figure 1).

Inorganics

For inorganic chemicals and complexes too numerous to mention, the TG750 can help in characterising new compounds, and in stating solvation, decomposition, dehydration, etc, etc.

Flame Retardants

TG can show at a glance the effect of adding flame retardants to a very wide range of fabrics and other materials. (See Figure 2).

Pharmaceuticals

Drugs usually have to be dry. TG is much quicker than older painstaking methods for determining the moisture content.

Moon Rocks and Babies' Bottoms

TG is currently among the many techniques being used on the moon samples.

It also provides a good way to determine the hexachlorophene content of baby powder

Other applications include:– kinetics, metal/plastic coatings, tooth decay, freeze-dried foods, gall stones, metal corrosion, lipid behaviours, catalyst effects, soils, etc, etc.

Your corner of science

Stanton Redcroft will be pleased to discuss the possibilities of Thermogravimetry for your current work. And if necessary do a few test runs for you in our own labs to find out just how useful TG could be to you.

We also make differential thermal analysers, temperature controllers and programmers and flammability equipment.

Stanton Redcroft TG750

Easy to use
Inexpensive
Compact design
Direct output
DTG facility
Wide range of heating rates

Operating temperature ambient to 1 000°C, weight capacit 1g, weight change sensitivity 1 to 250 mg f.s.d., air inert or reactive gas atmosphere, heating rates from 1 to 100°C per minute.

All backed by Stanton's 20 years' experience in the field of balances and thermal analysis.

Full details from:–

Volume 251 September 6, 1974

Should we publicise those experiments?

THE vigorous debate, started several weeks ago by the appeal from a panel of the National Academy of Sciences for self-restraint in pursuing research on certain types of plasmid engineering, does not as yet show any sign of waning. True, the number of scientists technically qualified to appreciate the risks involved and weigh them against other considerations is relatively small, but each of them is going to wish to make a very personal contribution to the discussion since it probably concerns his way of going about research in the future. Further, there are many more scientists who may understand little or nothing of the technical content of the appeal but who can envisage quite well the sort of feelings that are aroused when a distinguished group of scientists proposes a halt to certain research work.

One of the ramifications of the proposed ban is that scientific journals might wish to take note of it in their publication policy. Thus David Baltimore, one of the NAS committee members, said "editorial boards . . . will probably think twice about publishing research papers derived from experiments covered by the embargo", and Michael Stoker, Director of the Imperial Cancer Research Fund, wrote "editors . . . will also need to consider their policies in the face of wide support for a moratorium".

We are obviously capable of speaking only for *Nature* but it is our opinion that any policy that tries to eliminate from the journal reports of experiments that are believed—even widely believed—to be potentially dangerous would be quite wrong. We are unsure that editors of more specialised journals would necessarily feel similarly.

There are two reasons why we feel that *Nature* should not take a stand against such papers. The first is that asking a referee to remark on the morality of a paper (assuming that it is not a question of legality) cannot but lead to impossible situations. Should reports of nuclear fission have been called 'potentially dangerous' and in bad taste? Should scientific work emerging from nuclear detonations or weather modification be kept out of the literature? Is the administering of electric shocks to animals cruel? These are not questions which can safely be left to a referee with his own personal predilections, or even an editor with his, and to attempt to do so by putting an X in the box if you believe the experiment should never have been done in the first place is rather like asking a judge to deliver his verdict only after he has factored in to his decisions his own feelings about whether the law was a good one to start with. The community can either legislate against certain experiments or it can attempt to persuade practitioners to desist; if it tries to put the onus on an individual to decide for the community, it can hardly be surprised if the result is often quirky.

The second reason why we would not automatically decline papers describing things of which many would disapprove is that it is surely more important that these things be given publicity than that they be pushed into the underground.

This hardly means that we would actively solicit such manuscripts nor that we would be more likely to accept them in order to take advantage of their obviously unusual character. But if a scientist has chosen to ignore a widespread call then a case could occasionally be made for drawing the community's attention to who he is and what he is doing. Besides, proscribed experiments will need continued re-evaluation in the light of new techniques and new understandings, and it may be that research done in forbidden territory, however lacking in approval by a majority of scientists, positively helps in reinforcing or easing the moratorium.

We have a broad general sympathy with the aims of the NAS group and we recognise in their statement important ground-breaking in the scientific community. Nevertheless, we would not at present wish to commit ourselves to any blanket policy of turning away reports from those who work on regardless. The issue of publication, though, certainly merits an airing at next February's international meeting.

A hundred years ago

While progress has been made with gigantic strides in many directions, in engineering and in mechanics generally; while railways, steamboats, and electric telegraphs have extended their wonders to the most distant parts of the world; and while trade, with these aids, is bringing to our shores the produce even of the most distant places, to add to our comforts and our luxuries; yet, when we come to look to our homes, to the places where most of our population have to spend nearly the whole of their lives, I think we must find, with regret, that, in matters pertaining to the salubrity and general amenities of our towns and houses, as places for residence, due progress in improvement has not been made. Our house drainage arrangements are habitually disgracefully bad; and this I proclaim emphatically, alike in reference to the houses of the rich and the poor. We have got, since the early part of the present century, the benefit of the light of gas in our apartments; but we allow the pernicious products of combustion to gather in large quantities in the air we have to breathe; and in winter evenings we live with our heads in heated and vitiated air, while our feet are ventilated with a current of fresh, cold air, gliding along the floor towards the fireplace to be drawn uselessly up the chimney. A very few people have commenced to provide chimneys or flues to carry away the fumes of their more important gaslights, in like manner as we have chimneys for our ordinary fires. In mentioning this, however, as a suggestion of the course in which improvement ought to advance, I feel bound to offer a few words of caution against the introduction of flue pipes for the gas flames rashly, in such ways as to bring danger of their setting fire to the house.

From the Presidential Address of Prof James Thompson to the Mechanical Science Section of the British Association, in *Nature*, **10**, 393, Sept 10, 1874.

Senator Kennedy: inspired anti-foetal research bill.

Guinea-pig charters

A number of ethically questionable research practices brought to light recently in the United States have led to calls for tighter control of human experimentation. Colin Norman discusses some of the regulations which have been proposed and their effect on research.

MANY American scientists hoping to conduct experiments on their fellow men and women will soon have to submit the ethics of their research to intense scrutiny by a raft of committees before they can get any funds. Some will then find people constantly looking over their shoulders while they carry out their experiments, others will find whole avenues of research shut off by the federal government or by state and local laws. In short, the traditional freedom of the scientist to organise his work is about to see drastic changes.

Human experimentation, like presidential power, has recently been a subject of national debate thanks to some widely publicised examples of ethical bankruptcy. Such examples include allegations that a number of poor black men who were known to have syphilis were left untreated so that the course of their disease could be monitored, that prisoners have been subjected to painful and essentially pointless medical experiments and that several children have been left mentally maimed by psychosurgery. The allegations have led to strident demands for more control over human experimentation, and the vocal anti-abortion lobby in the United States has also left its mark in the area of foetal research.

The controls have come from four directions: Congress, the Department of Health, Education and Welfare (HEW), state and local governments, and the courts.

At the Congressional level, a bill has been passed and signed into law by former President Nixon which sets up an eleven-member national commission on human experimentation whose duty will be to draft a set of regulations to protect human subjects of biomedical and behavioural research. The commission, which should be established later this month, has been given two years to complete the task and has been asked to concentrate its attention on areas such as research with children, prisoners and the mentally disabled, where ethical and legal problems abound.

As for research on pregnant women and foetuses, the bill—a measure inspired by Senator Edward Kennedy called the National Research Act—imposes a four-month ban on federal support for research involving foetuses with beating hearts, before or after an induced abortion. While the ban is in effect, the commission will draw up regulations governing such research.

Meanwhile, HEW has been moving independently to strengthen controls over human experimentation supported by the National Institute of Health (NIH), the National Institute of Mental Health (NIMH), the Food and Drug Administration (FDA) and other HEW agencies.

The department has already imposed a blanket provision that human experimentation will only be supported at institutions which have established review committees to scrutinise the ethics of individual studies before application is made for funds, and it is now in the middle of devising extra protection for children, pregnant women, foetuses, prisoners and mental patients. Last week, HEW proposed some tough regulations in that regard.

At the state and local level, several laws have been passed which impose restrictions on foetal research, the most prominent being a recent move in Massachusetts to outlaw research on living foetuses, before or after abortion. While the federal regulations would simply cut off funding for such research, the state laws would make some types of foetal research a crime punishable by a stretch in jail.

As for the courts, the whole concept of legal consent to take part in research as it applies to children and mental patients is under challenge in at least two cases, and in Boston four doctors are now awaiting trial on charges arising from some foetal research they conducted in 1971. Thus, as is common practice in the United States, the courts are likely to define some of the parameters of social policy.

All these attempts to regulate the practice of human experimentation involve a delicate balancing act by weighing potential benefits to society from medical research against the possible risks to those who take part. It is a balancing act which has its roots in the preamble to the United States Constitution, which states that the Constitution is designed to "promote the general Welfare, and to secure the Blessings of Liberty".

According to Dr Donald T. Chalkley, chief of NIH's Instutional Relations Branch, which has been drafting the HEW regulations, the real problem is that "we have a public concept of research that is based on fiction—on Clockwork Orange or Lord of the Flies experiments—but 90% of the research involves no more than the taking of a blood sample". This public concept is causing legislators to pass unduly restrictive laws, such as the blanket ban on foetal research.

Although stopping well short of imposing a flat ban on research involving living foetuses, HEW's proposed regulations would severely restrict such studies, and outlaw some kinds of research entirely. In short, such experiments would be subjected to three separate ethical checks, and they would have to be confined to a very narrow range of experiments in order to qualify for HEW support.

Ruled out would be a wide range of experiments on foetuses *in utero*, before they are aborted. Such prohibitions are also embodied in the Massachusetts foetal research law, and when that law was being debated, many scientists warned that the effect would be to stop a number of valuable research projects, and possibly to place future generations of children at risk.

The prohibition would prevent drugs or vaccines being administered to pregnant women about to undergo abortions in order to see whether they cross the placenta into the foetus For some substances, such as rubella vaccine, such knowledge is essential because of the dangers that foetal abnormalities may be caused if the substance does cross the placenta Dr Chalkley acknowledged in an interview last week that banning such research could place children at risk, but he pointed out that the problem is to balance the individual rights of the foetus and its mother against the potential promotion of the general welfare of children, both of which are equally protected by the Constitution

HEW also chose to draw the line against foetal research *in utero,* which is not designed to benefit the mother or that particular foetus, because if the foetus is placed at risk by such experiments, it would be very difficult for the mother to change her mind about going through with the abortion

It is worth pointing out, however, that although the HEW proposals would permit experiments designed to benefit the mother or the foetus, they would rule out control experiments because they ban all non-therapeutic studies on living foetuses

If the setting of regulations governing foetal research is fraught with difficulty, the situation regarding research on children is even more difficult The benefits from paediatric research are obvious, but the ethical and legal problems are also legion, and HEW, which has been trying to set some regulations in this area for the past couple of years has so far been unable to do so

The problem is essentially two-fold First, there is the difficulty of defining what kinds of research should be permitted and what should be outlawed As Chalkley put it last week, if you shut off an area of research now because the potential benefits are outweighed by the risks, you may be opening the door to new diseases And second, there is the problem of getting informed consent from minors

Can a parent or guardian legally and morally consent to have his or her child take part in a research project which might involve some risk, but which will not benefit the child directly? A law suit, filed against the University of California by an attorney, James R Nielsen, contends that no "invasive" medical research procedures should be practised on a normal healthy child unless they hold potential direct benefit for the child

Again, if research directly beneficial to the child is allowed but every other type of paediatric research is outlawed, one effect would be to prevent the use of control groups in any such experiment Clearly, the issue of human experimentation is far from dead, and verbal battles will be fought on a variety of fronts But at present the course of events at the federal level is far from clear

The most likely scenario, is that HEW (open for comments until November) will put its regulations into effect next year, and the commission will suggest amendments in 1976 ☐

LAST month, the US Department of Health, Education and Welfare (HEW) proposed some tough regulations governing research on prisoners, mental patients, pregnant women and foetuses Designed to protect the rights of those being experimented upon, the regulations would establish a number of ethical checks on research projects, and even ban some types of experiments entirely

First, under regulations already in effect, every institution in receipt of funds from HEW must establish an Organisational Review Committee, composed of people from a variety of occupations, to review research protocols involving human experimentation before they are submitted to HEW for funding This first ethical check will weigh the benefits to be derived from the experiment against the risks to those taking part, and it will also ensure that adequate provision is made for obtaining informed consent from the subjects

In addition, HEW is now proposing that another committee—the Consent Committee—be established at the institutional level to provide continuing ethical review of experiments involving prisoners, mental patients and pregnant women This committee will oversee the actual selection of subjects, make sure that they consent to take part without coercion and after having been fully informed of the risks, and that they are able to opt out at any stage if they no longer want to take part The new HEW proposals would also impose the following restrictions

- By far the most controversial portion of the proposed regulations deals with research on pregnant women and foetuses First, HEW is suggesting that yet another ethical check be applied to such studies from an Ethical Advisory Board, to be established in every HEW agency funding foetal research

These boards, which would consist of members appointed by the Secretary of HEW, from outside the government would review all grant applications for such studies after they have been approved by Organisational Review Committees

All research involving foetuses *in utero* on pregnant women would, however, be banned unless (a) "the purpose of the activity is to benefit the particular foetus or to respond to the health needs of the mother", or (b) the research is aimed at "evaluating or improving methods of prenatal diagnosis, methods of prevention of premature birth, or methods of intervention to offset the effects of genetic abnormality or cengenital injury", in which case, "the activity [must be] conducted as part of (but not prior to the commencement of) a procedure to terminate the pregnancy" The mother's consent would be required for such research, and the researcher should have no part in determining either the timing or method of abortion or the viability of the foetus

As for research on abortuses, the proposed regulations would require that relevant animal studies first be completed, that the mother's (and if possible the father's) consent be given, and that the vital functions of the abortus are not artificially maintained Furthermore, HEW is proposing that experimental procedures which would terminate the heartbeat or respiration of the foetus should be banned, but it stops short of calling for complete cessation of studies on foetuses with beating hearts

- As far as research on prisoners is concerned, HEW suggests that an Organisation Review Committee and a Consent Committee should provide adequate protection for research subjects, by making sure that prisoners are offered no special inducements or threats to make them take part A preamble to the regulations specifically rejects the notion that since prisoners have little freedom of choice in anything, they are incapable of freely giving their consent to take part in research projects
- Involuntarily detained mental patients pose a slightly more difficult problem The regulations, however, would permit research on such people provided that the study is "related to the etiology, pathogenesis, prevention, diagnosis, or treatment of mental disability or the management, training, or rehabilitation of the mentally disabled and seeks information which cannot be obtained from subjects who are not institutionalised mentally disabled"

In other words, HEW is attempting to rule out the use of mental patients for studies unrelated to their mental illness

The proposed regulations are available from the Institutional Relations Branch, Division of Research Grants, NIH, Bethesda, Md 20014, USA

international news

B.A.—first the bad news

OPENING this year's British Association conference at Stirling, the President, Sir John Kendrew, called for changing attitudes amongst scientists to counteract the growing indifference and even hostility towards science shown by the non-scientific public

A note of gloom pervaded the first few minutes of the address, as Sir John outlined the problems facing the practice of science today The relationship of science with society has become slightly defensive on the part of the scientists Increasing financial restraint on scientific research and the downgrading of scientific adviser posts both in Britain and the United States have not helped matters

The hostility towards science arose because people saw it as the handmaiden of economic growth, as the creator of pollution, as a support for the military and as a source of little understood dangers such as genetic engineering and computer data banks, or even as a negation of humanity itself

But, said Sir John, changing to a more optimistic note, the scientists' feelings of pessimism and guilt are unjustified Science has proved itself in the past and there will be an absolute need for science in the future But hostile critics will only be converted by a change in scientists' attitudes Scientists must focus on the challenges which will face us in the future and be less despondent about some of the immediate practical difficulties

The main challenge was to decrease the widening gap between our standards of living and those of the poorer peoples Whether we favour a "growth" or a 'no-growth" society said Sir John, we could not be content that a no-growth society should involve most of the world's population living in undernourishment, squalor and disease

The concept that the pursuit of knowledge as an absolute good in itself was the prime motive of scientific research needed to be re-examined, said Sir John Although a good motive, it had not been, nor ever could be the only one After the War, in which many scientists had applied their skills, there had been a reaction towards pure research for its own sake, he said But the world had changed since the 1950s and the challenges had changed, too "In my view," said Sir John, "it is neither socially productive nor intellectually satisfying to refuse to modify the old attitudes or to respond to the new challenges " Much contemporary research might seem to future historians like the minute and pettifogging scholasticism of mediaeval times

Even the increasingly tight research budgets might compel scientists to direct research into fields that may actually turn out to be more productive than those that could be afforded in times of plenty Limited budgets could also be optimised through international cooperation, despite the pitfalls of bureaucracy, politics and commercial restraint

Sir John went on to discuss specifically the problems arising from the genetic manipulation of bacteria, an example of a scientific advance which could hold dangers for the human race and which has recently been much debated in public

In these experiments. pieces from animals or viruses can be linked with bacterial DNA in such a way that the complete DNA molecule can replicate inside a bacterium It was feared that the deliberate or accidental introduction of cancer-causing genes into bacteria for further study—an admirable end in itself—could lead to these genes becoming widely disseminated in the human and animal population, since the organism most widely used for this type of work was the common gut bacterium, *Escherichia coli* But the incorporation of certain animal genes making useful products could be of great benefit No-one yet knew or could foresee, all the possible dangers as these techniques were still relatively untried

Sir John drew an analogy with the state of nuclear physics at the beginning of the last War, when it became clear that nuclear fission could make possible the development of new power sources but could also be used to construct an atomic bomb

He approved the action of some American scientists and the British Medical Research Council in calling for a voluntary moratorium until the dangers of this work had been evaluated A permanent international body made up of molecular biologists themselves, should recommend what types of experiments should or should not be carried out and under what conditions of security Also a fact-finding programme of research in this area should be conducted under conditions of high security and the results published fully in the open scientific literature

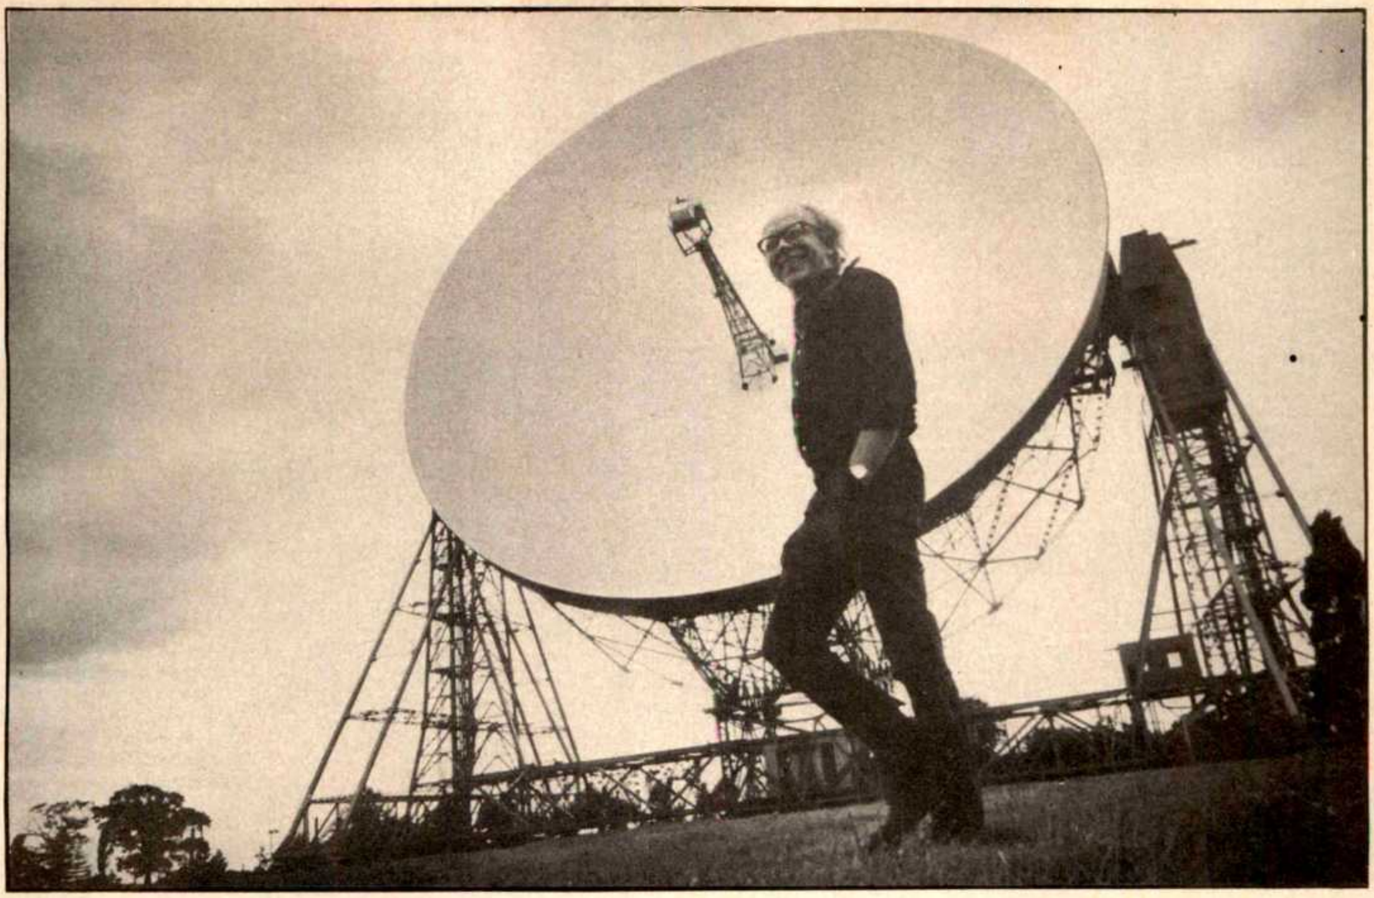
This was a case, he said, where scientists must be seen to put their own house in order, or else others would step in and do it for them perhaps in ways which would lead to quite undesirable restrictions on what they do

Even when decisions passed to the social or political forum, it was absolutely necessary that there should be effective communication of scientific knowledge upon which decisions could be based Communication of science to the general public seemed to be failing at present and scientists should take trouble to translate their ideas and discoveries into language which anyone could understand ☐

Science is fun

ON Saturday, August 31, Westfield College of the University of London held a carnival of science which it dubbed 'WES-POP' The idea for this feast of fun grew out of a similar but larger event held at Aix-en-Provence last year That event —AIX-POP—was arranged to coincide with a gathering of scientists from many nations for a conference on elementary particles In spite of some initial scepticism among the physicists cajoled into cooperating, AIX-POP proved a roaring success, in that hundreds of ordinary citizens were brought into contact with the scientists in small groups, where the scientists were forced to communicate intelligibly at a personal level

Professor Elliot Leader, of Westfield College, was one of the participants in the Aix event, and was sufficiently enthusiastic about the idea to organise something along the same lines in north-west London The event was widely publicised locally by means of posters in fairground style offering such treats as "See your friends bombarded by cosmic rays! " and "Watch the amazing lasers in action" And further publicity was lavishly provided by the local newspaper, which allowed Professor Leader space for three feature articles about physics and the festival—that in itself is remarkable enough for any British newspaper ☐



New director for the RGO

by John Gribbin

Professor F. Graham Smith, presently Professor of Radio Astronomy at the University of Manchester, is to succeed Dr Alan Hunter as Director of the Royal Greenwich Observatory (RGO) at Herstmonceux, Sussex. Stated that baldly, the appointment might cause consternation—what could be in the minds of the members of the Science Research Council (SRC) that they should appoint a radio astronomer to head England's principal optical observatory? But this superficially bizarre decision will not seem so odd to anyone who has followed the recent development of astronomy in Britain, nor to anyone who is familiar with Professor Smith's career; indeed, this could be one of the best things to happen to optical astronomy in Britain for a long time.

The situation has been confused, of course, by Professor Margaret Burbidge's brief yet stormy reign as Director of the RGO. On her resignation the then Deputy Director, Dr Hunter, took over the top job. But that could only be an interim appointment, since Dr Hunter reaches retiring age at the end of 1975, after 38 years with the observatory.

Now that situation is resolved. Professor Smith (pictured above at Jodrell Bank) will join the RGO staff this autumn, and will serve as deputy to Dr Hunter until the end of 1975. This should be ample time for him to learn the ropes, if past experience is anything to go by.

Professor Smith is far from being a narrow specialist in radio astronomical matters. Now 41, he completed the bulk of his formal education before radio astronomy developed as a discipline in its own right, and his PhD (awarded in 1952) must have been one of the very first awarded by the University of Cambridge for radio astronomy work. Following spells at the Telecommunications Research Establishment, Malvern, and at the Cavendish, he moved to his present post in Manchester in 1964. There can be no doubt that his influence is in no small measure responsible for the fact that Manchester is now recognised as a place where first class theoretical work in the field is done, as well as being the home of one of the world's leading radio astronomy observatories. In particular, Professor Smith has recently worked on theories of the emission mechanism of pulsars, cosmic rays and galactic radio sources.

In 1969, Professor Smith gained something of a reputation as a troubleshooter for the SRC, when he spent 10 months as Deputy Director of the Radio and Space Research Station (now the Appleton Laboratory) to assist with a review of the station's research policy. So Professor Smith takes with him to Herstmonceux a thorough knowledge of the workings of the SRC machinery and a great deal of administrative experience. There seems no likelihood that this appointment will fail either through personal conflicts between the Director and the SRC or through any lack of ability, and the RGO can thus look forward to a prolonged period of stable development. It is too early yet to see what direction that development will take, although the fact of stability alone will be welcome enough after recent troubles. But Professor Smith told *Nature* that he was particularly anxious to move to the RGO at once, rather than wait until 1975, in order to be fully involved with developing the proposed Northern Hemisphere Observatory. He emphasised that this is "a marvellous opportunity" to get to grips with the engineering side of optical astronomy, and to meet the people involved on a working basis, before he disappears into an office labelled 'Director'.

After much prevarication, that Northern Hemisphere Observatory now at last looks like becoming a reality. With Professor Smith playing an important role, and with the SRC's infrared telescope now definitely intended for a Hawaiian home, it begins to look as if there really will be a Northern Hemisphere Observatory, almost certainly in Hawaii, in the not too distant future. □

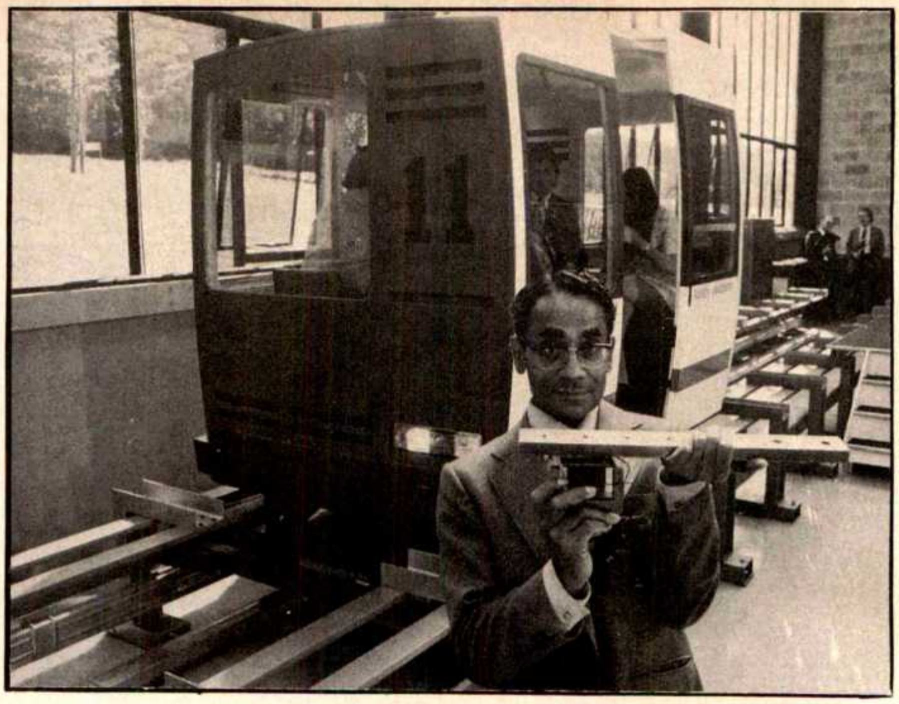
The case of the cancelled hovertrain

by Angela Croome

THE case of the British Government-funded experimental development of the hovertrain on which a White Paper (Tracked Hovercraft Ltd, Cmnd 5711) has just been issued is a classical example of how not to manage an innovative high-technology assessment project. What is so especially discouraging is that the sequence to cancellation could be predicted five years—and £5¼ million—earlier with very considerable reliability. More must have been written and minuted in Britain on the subject of fostering and managing technological innovation than almost any other technological subject since the last World War. Yet no lessons seem to have been learnt; no guidelines derived.

The White Paper has been produced under pressure from Parliament's Select Committee on Science and Technology which held an inquiry which took up much of the first half of 1973 and some 500 pages of reports, into the circumstances surrounding the close-down of Tracked Hovercraft Ltd. and its full-scale vehicle test track near Cambridge. The summary Report (July 24, 1973) of the Select Committee was very critical of almost every aspect of the business—of the cancellation of the project no less than the manner in which it was done (the bulk of the 150 staff were given less than 24 hours to be out of their offices, for example); of the Government's role, of the way innovation is managed (or mismanaged) in Britain and the adequacy of the National Research Development Corporation for this task. It specifically proposed that there should be a 'high-level' review of the organisation needed to develop innovation and asked that the Government look again at the 1972 Select Committee recommendation of a small expert Department headed by a Cabinet Minister to look after Government sponsored R and D; further, that the THL test track at Earith should not be scrapped but become a multiuser research facility run by a consortium of British universities with interests in novel surface transport and headed by Imperial College.

The White Paper in response to this swingeing assault can only be described as a mouse. It dodges out of dealing with the main criticisms by attributing them to a previous Government for which it was not responsible. Apart from enunciating the principle that "no promising technology ought to be stifled in infancy for lack of funds" it expresses entire satisfaction "that departmental organisations, supplemented by the NRDC, provide adequate machinery for Government participation in the development and exploitation of inventions". As to providing some funds for maintaining the Earith test track as a multi-user facility, it denies the need for such a centre and by withdrawing restrictions on dismantling it laid down last year invites the speedy scrapping of the track. In the overall field of high speed public transport "the Government considers that the present effort and expense are appropriate in scale and pace".



Professor Bhalchandra Jayavant demonstrates the principle of the Sussex magnetic train: all right for Brighton front, but how good at speed?

The present effort and expense in this field amount to this. There is the multi-million pound British Rail development of the Advanced Passenger Train (APT) envisaged as running at up to 250 mph and coming into service on existing rail tracks in the 1980s. The development of the linear induction motor for fast tracked vehicle propulsions which THL at Cambridge had been fostering through its links with Professor Eric Laithwaite at Imperial College has been passed to the Brush subsidiary of Hawker Siddeley with a £400,000 Government grant against an investment of £100,000 by the company which it has been remarked has never made a linear motor before. The Wolfson Foundation has put about a quarter of a million into research into mass transport vehicles employing magnetic propulsion and/or levitation, notably at Sussex and Warwick universities. Now the Science Research Council is putting up some funds for similar work in the universities. Two things may be said about this pattern of effort. None of the work—save possibly some of that in the universities—looks beyond 1985, the date which in his much-criticised evidence to the Select Committee the previous Transport Minister (Mr Peyton) considered his departmental limit. Secondly, coordination of these activities now involves three ministries and the public sector. The dangers of fragmentation of effort have been reiterated continually during the debate on the organisation of government R and D no less than over the Tracked Hovercraft inquiry. If communication and coordination was inadequate when only British Rail's APT project and NRDC's THL were involved as the Select Committee indicated, how much worse is it going to be now?

A glance at the scale and pace of effort in other countries provides some sharp contrasts. Japan has perhaps the largest programme in high speed mass transport development. It is costed in thousands of millions, very long-term, much interested in electro-magnetic levitation employing cryogenics and no less than 60 professors are said to be involved full time. The United States has in August taken the opposite step taken by the British Government last year by dropping further work on its high speed passenger train (called the Improved Passenger Train Project) and switching the $5.6 million involved into support of tracked hovercraft transport. A huge test site is under construction in the Colorado desert where five different types of trackway amounting to some 70 miles altogether are being laid out as the High Speed Ground Test Center to test types of high speed propulsion including linear motors and suspension including both air cushion and mag-lev (magnetic levitation); as well as alternative modes

Biomedical advances give rise to concern

Topics of public concern arising from recent medical advances are given an airing in the British Association's most recent publication, *Social Concern and Biological Advances* (British Association, 50p).

A wide-ranging committee of scientists, lawyers, Members of Parliament, theologians and others was set up in 1972 to investigate the social, ethical and legal implications of certain medical advances, notably those in the fields of *in vitro* fertilisation and genetic manipulation.

Discussing artificial insemination by donor (AID) the committee consider that the legal status of any child conceived through AID needs to be properly defined as such children now occupy a twilight sub-legal zone. The genetic makeup of the donor is another important issue, and the committee call for a decision as to whether prospective sperm donors should be examined medically and as far as it is possible, genetically. The control of sperm storage banks is another problem of some concern. The government should decide immediately whether private banks are to be allowed and standards and supervision for such banks should be defined.

The committee recommends that research on *in vitro* fertilisation should continue as its possible advantages outweigh potential disadvantages. But there is the potential for abuse, and so the medical profession and government should keep a careful eye on new developments in this field and should be prepared to act quickly to prevent abuse.

Genetic screening for some genetically determined crippling diseases is now relatively common. Although this is superficially of great potential for reducing the numbers of children born with severe mental and physical abnormalities, the moral problems at both the social and personal levels can cause acute distress.

Social attitudes towards abortion can influence both the doctor's recommendation and the mother's response when an abnormality it detected especially in borderline cases where the degree of the abnormality cannot be predicted precisely. Less obvious but equally distressing, is the risk that a woman carrying an affected foetus could be subjected to social censure if she refused to be screened or undergo an abortion. This censure could also carry over to the child itself.

Under the broad heading of genetic engineering, eugenics and pre-natal sexing, the committee considers gene therapy, potentially useful but still experimental; sterilisation of people carrying defective genes; and the possibility of being able to choose the sex of one's child.

A policy of selective sterilisation needs to be scrutinised particularly carefully, as individual rights must be protected and the definition of 'normality' can be open to abuse by political and social systems which seek to manipulate it for their own ends. The committee make no specific recommendations on this head but advise continuing review of developments in this field.

The committee seem undecided as to whether pre-natal sexing will have much appeal for Western societies but recommend that official bodies should be prepared to act quickly to prevent precipitous and unadvised applications of new sex selection procedures.

The report also covers the chief moral problems involved in organ transplantation such as defining the moment of death and the ownership of the dead body. "Any definition of death" it says, "implies an understanding of what constitutes life".

The 1961 Human Tissues Act covers the transplantation of organs but is unsatisfactory on some points. Under this Act the legal possessor of the dead body can authorise the removal of the organs. But who, asks the committee, is the legal possessor, and what constitutes a reasonable inquiry to gain permission from relatives to remove organs for transplantation? Also, should Britain operate a "contracting in" or a "contracting out" system whereby people indicate whether or not they wish their organs to be used after death?

The committee favour adopting some of the recommendations of the 1969 McLennan Committee. These are that the present system should stand but that it needs legal reinterpretation to remove ambiguities and to facilitate the supply of organs to transplantation. Registers should be kept both of those who wish to contract out, and on the other side of the coin, those who specifically wish to donate organs after their death should also be registered.

---

of urban transport.

In Germany 45 miles of test track are now planned at a site near Augsburg and very large public sums (£100m for R and D alone) have been invested in high speed transport for the future with particular emphasis going to linear motor development and magnetic levitation. Krauss Maffei which won the contract for the Toronto project at about the period that the Government announced the cancellation of the tracked hovecraft has switched its design from the 'conventional' double-sided linear motor to the single-sided type first conceived by Professor Laithwaite and 'proved' on the THL vehicle which Krauss Maffei had visited.

In the light of this amount of world activity and interest the ostensible reason for last year's Government cancellation of the tracked hovercraft, that there was no customer or market for it, seems extraordinarily thin. In fact some of the by-products of THL—the single-sided linear induction motor, the box-beam track for instance—have, as described, been adopted in overseas projects. The Select Committee accepted that Britain had about a five-year lead in overall hovertrain technology—and this was being reflected in consultancy fees particularly in North America. Professor Laithwaite's even more recent breakthrough which he calls the 'magnetic river' and which offers propulsion and controlled suspension in three axes from the same transverse-flux linear motor running on normal mains AC seems to put British research in the field of high speed transport even further ahead. Professor Laithwaite claims that he will have a production prototype of this double-purpose motor within six months, and it is particularly suitable for speeds of over 250 mph (where British Rail's APT runs out). Similar claims for the University of Sussex electro-magnetic attraction system, recently demonstrated in an urban passenger carrying version being devoloped for a 2½-mile shuttle along Brighton front, seem likely to be misplaced. Over 50 mph, a serious drag, develops from eddy-currents set up in the track (a problem that Krauss Maffei are encountering in the Toronto project now). One is forced to believe that the only customers that the British Government's chief scientist departments accept are home customers and that in the case of the tracked hovercraft it was especially unfortunate that the customer department DoE was also the sponsoring department of British Rail and its pet the APT. Customers beyond 1985 are not being considered and their seems no mechanism for considering the general public as a customer.

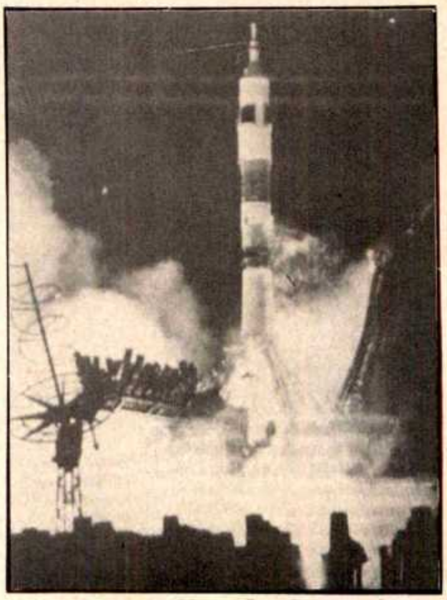
The Government has turned down the Imperial College form of proposal for keeping the Earith test track in being. Several practical problems now arise. The estimated cost of dismantling the track is £200,000 and THL has no funds left so the Government will

Soyuz – 15: didn't fall, wasn't pushed

from Vera Rich

THE brief flight of Soyuz-15 (August 26-28) has led to considerable speculation as to some possible failure which may have led to its curtailment. The report of a naked-eye sighting of Soyuz-15, which at 4.30 a.m. (GMT) on August 28 was seen to have overtaken the orbiting space-station Salyut-3, suggested that something had gone amiss, preventing an intended docking of the two craft.

In fact, however, the official *Tass* reports do little to substantiate these speculations. Although the first statement does mention Salyut-3 it does so only in an oblique manner, stating that: "The purpose of the launch of Soyuz-15 is the continuation of the scientific research and experiments in outer space begun on July 3 of this year in the flight of the transport ship Soyuz-14 and the station Salyut-3". The mention of Salyut-3 certainly suggested that the two craft would, in some way, participate in a joint experiment; the next *Tass* release, however, stated clearly that this would not be a link-up. The experiements were intended "to work out techniques of piloting the craft in different regimes of flight. In the process of manoeuvering the craft, Soyuz-15 made a number of approaches to the Salyut-3 station. The cosmonauts controlled the operation of all systems of the ship, carrying out observations of the stages of approach to the station". Soyuz-15, the release continued, was now preparing to return to earth.



Soyuz-15 blast-off: AP wire picture.

The *Tass* account of the descent stressed the details of the flight procedure—the use of the braking motors to align the craft before descent, the release of the parachute system and the firing of the braking motors immediately before touchdown. The aim of this last stage of the experiment was to test "methods and means of finding and evacuating a spaceship which had landed in night conditions". This was the first true night landing, although Soyuz-10 landed in predawn conditions. The search and recovery stage of Soviet space ventures has always held its own special hazards—one early pair of cosmonauts had to fight their way back to civilisation through the snow for two days Nevertheless, according to V. A. Shatanov, the commander of Soyuz-10, the need to practise night-landing is becoming more and more necessary, since the necessity to land at a given time of day imposes rigid conditions on the flight-plan even before take-off.

Tass reports are traditionally brief and uncommunicative, frustrating the desire for further information with such phrases as "according to its assigned programme", or "carried out its aims", without specifying full details of that programme or those aims. They are in a style therefore admirably suited to effect a cover-up of a partially aborted programme. But what if the speculations are wrong, and there was no break-down, and Soyuz-15 was planned from the beginning as a two-day mission. The need to practise night-landing, thereby eliminating rigidity of the flight plan, fits in well with the plans for the joint Soyuz-Apollo programme planned for 1975. (There could be considerable loss of face if either party had to ask for a revision of the joint flight-plan because its crew and ground support could not manage a landing under such-and-such conditions!) The practice of docking approaches from various positions, and the insistence that the cosmonauts were in total control of the craft is also interesting. There has always been a tendency in the Soviet manned space programme to incorporate a certain amount of ground control — the early cosmonauts were little more than passengers in the craft that carried them.

Speculation has suggested some technical failure in the Soyuz-15 craft, with possible setbacks to the Soyuz-Apollo programme. This may be the true explanation—but there remains the possibility that he *Tass* statements, do give, albeit briefly, the real objectives of the mission; that the flight of Soyuz-15 was intended simply to test out tricky manoeuvres, so that, in the joint mission, Soviet prestige might be duly maintained, by Soviet cosmonauts able to perform their part of the mission even in adverse circumstances—making docking approaches from any position, and able to cope with a touchdown at any hour of the day or night.

---

have to find some kind of subvention to enable the company to remove the one mile existing track. There are two further miles of track in the form of unassembled beams in store at the manufacturers. What is to be done with them? With THL in nominal existence only, how are the numerous patents and the accumulated expertise to be exploited? It is impossible that the last has been heard of the tracked hovercraft and its company. Professor Laithwaite and his magnetic river are probably its greatest 'liquid' asset. He has not been heard from since the White Paper's publication but it is understood that alternative support is under discussion for the track and the plan to make it part of a possible joint European rapid transit centre.

There is a meeting of the EEC intercity working party in October in which ex-THL staff take part. The Select Committee may be regretting the move which enabled the Government to publish its meagre response while Parliament was in recess. This does not reflect on the excellence and thoroughness of the Committee's original Report and inquiry and there must be every expectation that it will either call for more evidence or make its views known through a debate on the White Paper as soon as Parliament is reconvened possibly accompanied by a further publication.

As to the sorry tale of the hovertrain's relevance for the bigger issue of the proper support of innovation today, Sir Christopher Cockerell, inventor of the parent concept, the hovercraft, gives the best summary (in a Memorandum to the Select Committee):

"To carry through a major development, a powerful lobby is required — example, Concorde; or a very powerful position — example British Rail and the high speed train; or prestige and many jobs at stake—example, Rolls Royce and the RB 211. . . . Now consider a brand new idea. It starts with neither money, facilities, a proven performance, a proven market, a lobby, prestige, jobs at stake, nor even people who understand it. . . . What is missing for big projects is a suitable machinery to cover the stages between NRDC's limited support and the fully commercial stage". □

news and views

Development of hominid locomotion

THE uniqueness of the human locomotor pattern has fascinated students of evolution for a long time and the past few years have seen an important increase in the complexity, detail and scope of locomotor studies Erect bipedalism is, of course, not found solely in man, but it is a rare form of locomotion in the animal world and both the reasons for its development and the nature of that development itself have stimulated much research

Although there is no consensus regarding why erect bipedalism has characterised the human lineage for at least several millions of years, there seems to be some agreement that no single factor 'caused' bipedality In other words, a combination of environmental and behavioural situations, combined with genetic changes, probably worked together in a positive feedback relationship For example, changes in the environment and behaviour might have provided new selective backgrounds favouring the incorporation of genetic advances in manual flexibility and dexterity, cerebral complexity and bipedality Changes of such physiological and anatomical nature could, in turn, provide new bases for further behavioural developments In this way, the development of bipedality is not viewed as an isolated event but rather as just one facet of highly interrelated and even interdependent evolutionary processes This approach to mutual causality in processes of social, cultural and physical development has come to be called "the second cybernetics" (Maruyama, *Am Sci* **51**, 164–179, 1963) Such reasoning is an important advance over earlier chicken-egg hypotheses in that it delineates the evolutionary process as taking place on several levels simultaneously A logical extension of this point of view is to suggest that it is the interrelationships between the levels which are in fact evolving and not the levels themselves

Most of the recent studies on human locomotion, however, have been more concerned with analysis of its physical development and biochemical characteristics Many different types of investigations have been used, anatomy, biomechanics, radiography, cineradiography, electromyography, as well as multivariate statistical techniques, have all been focused on the evaluation of locomotor patterns in living primates (including man) and some of this work has been used to reconstruct locomotor patterns in fossil groups (see Oxnard, *Syst Zool* **22**, 409–424, 1973 for a recent review) One result of the palaeontological investigations has been that despite the rarity of erect bipedalism in the animal world probably two slightly different forms of this locomotor pattern have been present, apparently simultaneously, within the human lineage The two patterns are contemporary at Lake Rudolf possibly as early as 3 million years ago and this suggests a profound and early dichotomy within the Hominidae Good evidence of this separation exists in the skull and dentition (Leakey, *Nature*, **237**, 264, 1972, Day and Leakey, *Am J phys Anthrop*, **39**, 341–354, 1973) and it is also demonstrated in the postcranium, most clearly in the femur, talus and tibia

In the human fossil record the femur is the best represented bone of the postcranial skeleton and in the relatively large number of femora now available two distinct patterns seem to have emerged One of these, the 'australopithecine' pattern, shows a small femoral head with a long flattened neck, non-flaring greater trochanter and a high degree of shaft obliquity or tilt (Walker, *J hum Evol* **2**, 545–555, 1973) Material showing this pattern is known from South Africa (SK82 and 97), Olduvai Gorge (OH20) (Day, *Symp Zool Soc London*, No 33, 29, 1973) and East Rudolf (KNM-ER 738, 815, 736 and 1505, Walker *op cit*) Moreover, radiographic evidence of the internal structure shows some possible distinctions in a greater thickness of the shaft walls and in the orientation and distribution of the internal trabecular structures (Walker, *ibid*) Within the Lake Rudolf material a second morphological complex has been identified and this pattern conforms more closely with that seen in living man a larger femoral head, shorter and rounder neck and flaring greater trochanter are the most visible similarities KNM-ER 737 (Day and Leakey, *Am J phys Anthrop*, **39**, 341, 1973) and KNM-ER 1481 and 1473 (Leakey, *Nature*, **242**, 447, 1973) show this pattern and have, in fact, been attributed to the genus *Homo* Further evidence of the dichotomy may also exist within the talus The talus is an important bone for locomotor assessment since it acts as a hinge joint between the lower leg and the foot and in this position can potentially reveal much about the structure and function of the foot Though the talar specimens TM 1517 (from Kromdraai), Olduvai Hominid 8, and KNM-ER 1476 and 1500, show some interesting variations within the group they seem to form one morphological pattern TM 1517 and OH 8 have been intensively evaluated through anatomical and multivariate techniques (Day and Wood, *Man*, **3**, 440, 1968) and through multivariate techniques alone (Oxnard, 1973), OH 8 has been subjected additionally, to biomechanical analysis (Preuschoft, *Folia Primatal* **14**, 209–240, 1971) Although there is agreement that the two specimens share many features they may have differed somewhat in the orientation and functional capabilities of the great toe The suggestion of the Kromdraai talus is that the great toe was somewhat divergent (Le Gros Clark, *J Anat Lond* **81**, 300, 1947) and this may have resulted in a more flexible foot capable of "some climbing ability" (Robinson, *Early Hominid Posture and Locomotion*, University of Chicago Press, 1972) and some "grasping" ability (Le Gros Clark, *op cit*) The OH 8 specimen (a nearly complete foot), has, however, a great toe which is not significantly divergent although Preuschoft (*op cit*, page 213) has suggested that it may diverge slightly more than in the original reconstruction

Other talar material, notably KNM-ER 803 (Leakey, 1972 *op cit*) and KNM-ER 813 (Leakey, *ibid*, and Wood, *J Anat*, **117**, 203–204, 1973) has been attributed to *Homo* Although several fossil hominid tibia are now available from East Africa, no comprehensive study on this material has yet been completed and therefore any conclusions must remain very tentative Preliminary studies again suggest, however, the existence of two morphological, and presumably locomotive, patterns Among this material the partial skeleton, KNM-ER 1500 (including a tibia) and KNM-ER 1476 have been allocated to *Australopithecus* (Leakey, *Nature*, **242**, 447, 1973) Conversely, the partial skeleton, KNM-ER 803 (with a tibia) has been allocated to *Homo* (Day 1973, *op cit*), KNM-ER 1481 seems also to fall with this group (Leakey, 1973, *op cit*) The tibia and fibula from Bed I at Olduvai Gorge (OH 35) has been tentatively allocated to '*Homo habilis*' (Leakey, Tobias and Napier, *Nature,* **202,** 7, 1964) but in view of recent developments in the field (Leakey, *Nature,* **248,** 653, 1974) perhaps the criteria for this taxon should be re-evaluated

Thus several lines of investigation firmly suggest that a locomotor dichotomy existed within the bipedal early Pleistocene hominids Although the functional nature of this dichotomy is not yet entirely clear it may be that the striding gait of *Homo sapiens* was not present within the 'australopithecine' group (Day and Wood, *op cit*) Moreover, although some workers in the field insist on the use of a broad spectrum of analytical tools, there is a tendency in the recent literature to de-emphasise the importance of such comprehensive anatomical biomechanical and radiographic studies and to concentrate heavily if not exclusively on multivariate statistical evaluations The basic mechanism of this approach involves quantification of the specimen and then, in the case of fossil material, interpolation of a function of these measurements into a comparative matrix composed of measurements from living primate groups and perhaps other fossils This somewhat mechanistic approach, although admittedly useful as part of a broader study has important limitations when used as a total analytical approach First, some significant features of bones do not lend themselves to quantification The disposition, orientation and density of trabecular bone are such features, the development and orientation of muscular markings are others Second, such a method assumes that the locomotor pattern of the fossil has a known analogue such an assumption is unproven, especially with regard to the fossil Hominidae, since it now seems likely that the 'australopithecine' pattern was unique The hazards of this rather narrow approach were well demonstrated in a recent paper by Oxnard *op cit* On the basis of only eight parameters of the tali of TM 1517 and OH 8 Oxnard's results suggested that the australopithecine foot had "distinct morphological affinities with the genus *Pongo*"—an affinity clearly unlikely on the basis of the total morphological appearance of the nearly complete OH 8 foot

In summary investigations of the development of locomotion within the hominid lineage provides one of the more active and fascinating areas of palaeoanthropology today It is important, however, that such studies be as broadly based as possible and utilise the research tools, analytical methods and descriptive models of many disciplines and only in this way is constructive insight possible

From a Correspondent

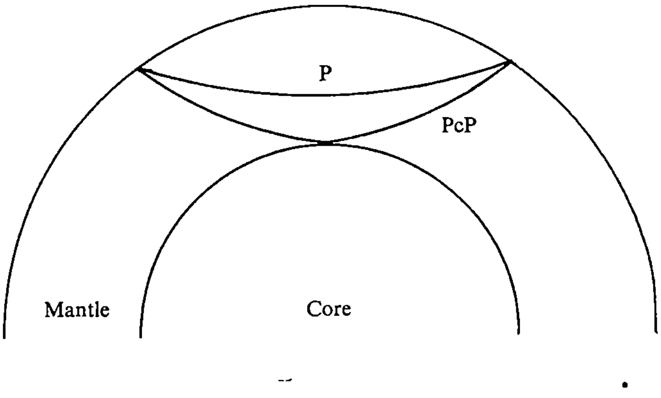
The Earth gets more complex

ONE of the major occupations of seismologists for many years has been to determine the travel time of compressional (P) waves and shear (S) waves through the deep interior of the Earth A knowledge of travel time as a function of distance from source to receiver is essential in locating earthquakes—it is also a most important ingredient in determining physical parameters of the Earth The more effort that has been expended, however, the further the goal has receded First, it became obvious that there were strong lateral variations in elastic properties (of the order of 5%) in the upper mantle, so that individual sources and receivers needed appropriate corrections Then in the past few years it has been increasingly clear that even below a depth of 700 km lateral variations persist An article by Jordan and Lynn (*J geophys Res* , **79,** 2679–85, 1974) highlights the advances now being made

It is interesting that the first authors to show that the assumption of lateral heterogeneity at great depths was unjustified did not consider travel times at all Travel times are relatively insensitive to the presence of inhomogeneities whereas the amplitude of the incoming signal and its direction of approach are much clearer indications of heterogeneity—although difficult quantities to invert for the purpose of making anything more than a qualitative statement In 1969 some observations were made of amplitudes at source–receiver distances which were well into the range in which the core should have shadowed out P waves (Phinney and Alexander, *J geophys Res* , **74,** 4967) It was clear that amplitude at a given distance was highly variable and depended entirely on which region of the core–mantle boundary was sampled in each particular instance Geophysicists are loath to consider substantial lateral variations within the core (perhaps that will change too) so there were clear indications either that the core boundary had strong topography on it or that the physical properties of the rocks at the bottom of the mantle are laterally variable—even to the extent of 5%

Then large arrays began to come into operation and results from them posed some problems, in that the angle of approach predicted by classical methods was often up to 5° away from the measured angle of approach This provoked much research from which there eventually emerged a feeling that the anomalies could not be properly explained without resort to marked lateral heterogeneity deep in the mantle (Davies and Sheppard, *Nature,* **239,** 318, 1972)

The time was ripe for another hard look at travel times and Julian and Sen Gupta (*Nature,* **242,** 443, 1973) came up with a very surprising result When every care was taken to avoid lateral heterogeneity in the upper mantle by using only very deep quakes as sources, and when the data were (as far as possible) not bunched together in a computer, from which only a mean could be extracted, significant patterns emerged By retaining a knowledge of the approximate path sampled by each data point, it was possible to see broad general regions in the deep mantle (mainly within a few hundred kilometres of the core–



Body-wave paths through the Earth's mantle

mantle boundary) out of which P waves emerged up to 1 s early or late relative to a standard travel time table Much of what in earlier studies had been regarded as general scatter arising from reading errors, crustal structure and so on was probably genuine evidence for deep lateral heterogeneity

Seismologists, one suspects, accepted the travel-time results more readily than they had the rather more circumstantial evidence from amplitudes and arrays In any case it now looked as if there was a whole new field of seismology opening up—mapping the deep mantle Jordan and Lynn's results point to a clear and fruitful way to go about it

On a seismic trace of a large earthquake many different signals can be identified and timed to a fraction of a second In addition to the P and S waves, phases called PcP and ScS are clearly visible—they are reflections of P and S waves from the core–mantle boundary If the time interval between the phases P and PcP is measured, it should, in a laterally homogeneous Earth, depend on source-receiver distance but not on anything else Furthermore, any deviations in elastic properties in source or receiver region will be sampled almost equally by the two phases, which follow paths in the upper mantle that are relatively close to each other Thus to a first approximation upper mantle anomalies are eliminated when the difference of times is taken

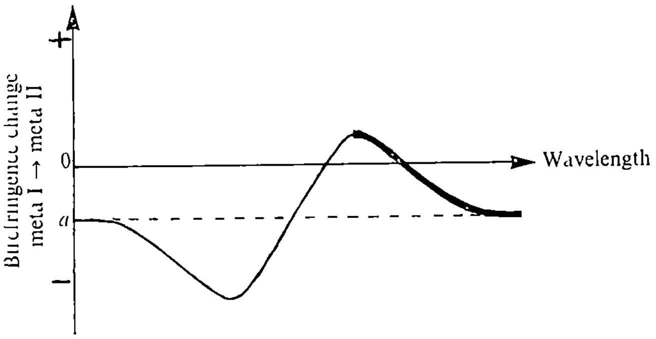
What Jordan and Lynn find is that for an earthquake in South America recorded across the North American continent, the PcP—P and ScS—S times by no means conform to standard travel time tables Along a certain azimuth in particular the differences are up to 1 s (PcP—P) and 4 s (ScS—S) away from the standard This, in seismological terms, is a significant deviation They go on to show that the anomaly most plausibly occurs along the path of the phases P and S, not the core-reflected phases, and so there is rather strong evidence for anomalous structure in a fairly narrow region at a depth of 600 to 1,400 km It is thought that the P-wave velocity is at least 1% (and probably more) greater than that of the surrounding material

Is this just a strange quirk of nature? Another stamp to go in a collection which could expand rapidly? More than that, I think Seismologists are often in danger of seeing their results as no more than information about seismic velocity in the Earth, but variation in velocity means variation in composition or temperature and that means a handle, however loose at present, on the geodynamics of the deep mantle Do plates penetrate beyond 700 km? Is the deep mantle in convection? How laterally variable in temperature is the core at its boundary? The results of the past few years are beginning to make these questions just a little more reasonable to ask with some hope of an answer in the foreseeable future

DAVID DAVIES

Birefringence and vision

IN the bleaching sequence of the visual pigment rhodopsin, the main spectral absorption shift (480→380 nm) occurs in the step between photochemical intermediates metarhodopsin I and II This is observed in both intact rod outer segment membranes (Liebman, *Biophys J*, **2**, 161, 1962) and in detergent-solubilised preparations (Hubbard, Bownds and Yoshizawa, *Cold Spring Harb Symp quant Biol*, **30**, 310, 1965) This step may involve an unfolding or other conformational change of the opsin protein which could produce the primary physiological response in vision There are several lines of evidence in support of this idea The Schiff's base bond attaching the retinal chromophore to the protein becomes chemically accessible at this step in solution (Bownds and Wald, *Nature*, **205**, 254, 1965), and probably in intact rods (Falk and Fatt, *J Physiol*, **183**, 211, 1966) There is also evidence for a conformational change in the protein on bleaching not specifically linked to the meta I→meta II step Hubbard *et al* (*ibid*, 1965) inferred a conformational change in solution from ultraviolet absorption spectra An increase in solubilised hydrodynamic volume has been observed by Heller (*Biochem J*, **7**, 2914, 1968) Circular dichroism measurements, which would be specific to protein conformational changes *in situ*, have indicated a change in solubilised pigment, but this change does not persist in the membrane (Shichi, *Expl Eye Res*, **17**, 533, 1973)



In this issue of *Nature* (see page 31) Liebman, Jagger, Kaplan and Bargoot report a study on the conformational changes in rod outer segment membranes by optical methods similar to those used on excitable membranes In the case of excitable membranes, there is a birefringence increase during the action potential (Cohen, *Physiol Revs*, **53**, 373, 1973) but in bleaching photoreceptor membranes there is a birefringence loss What do these observations mean?

The refractive index of a material is the ratio of the speed of light in vacuum to the speed of light in the material, and a birefringent substance has different refractive indices for light polarised in different planes In lipid bilayer membranes, where the hydrocarbon chains are aligned on average perpendicular to the plane of the membrane, the refractive index for the direction parallel to the chain axis is greater than that for the perpendicular direction The birefringence, Δn, is the difference between the refractive indices for these two directions $\Delta n = n_{\parallel} - n_{\perp}$ n and Δn are functions of the wavelength at which they are measured, so dispersion phenomena result Δn is greater for crystalline arrangements of the lipid chains than for more fluid, disordered ones where the chain orientation is less well defined The disk membrane is not only composed of lipid, however about half the volume is protein, which may also be anisotropically arranged The birefringence resulting from molecular organisation is called intrinsic birefringence, and that arising from the stacked arrangement of rod outer segment membranes is known as form birefringence The Δn of rods, observed to be positive, is the sum of the form birefringence, negative for a pile of parallel sheets, and the intrinsic component, which must therefore be positive and larger in magnitude than the form component (Schmidt, *Kolloidzeitschrift*, **85**, 137, 1938) It is the intrinsic Δn which tells us about the molecular orientations in disk membrane, although it cannot distinguish between the membrane constituents Form and intrinsic contributions to Δn can in principle be separated, if $n_{\text{cytoplasm}}$ can be varied independently of n_{membrane}, until the form component is eliminated This requires that the methods used to vary $n_{\text{cytoplasm}}$ have no effect on the membrane spacing, structure or thickness

Liebman *et al* first recorded a birefringence spectrum of dark adapted rods in the visible region, then followed the changes in Δn during bleaching They found a birefringence change appearing at about the rate of the metarhodopsin I→II step, the 'birefringence transient' (BRT) The figure is a schematic diagram of the fast birefringence change plotted against wavelength This curve can be fitted by the sum of two components, one resulting from the optical effects of bleaching, and the other directly caused by changes in the membrane The first component can be calculated theoretically, and it has the shape of the curve shown, but its position is shifted upwards so that it is centred on the axis at zero BRT The observed change is indicated by the heavier portion of the curve Once the effect of pigment absorption loss is accounted for, what is left is simply a constant (over the wavelength band measured) birefringence loss This birefringence loss is attributed to a change in the intrinsic birefringence of the membrane As in the case of nerve, there are many ways of explaining this change in terms of molecular events It could be due to any combination of small reorientations of lipid or protein, or slightly increased disorder Nevertheless, Liebman *et al* have detected a small change which may signal the start of the visual impulse

HELEN SAIBIL

Astrophysics and energy from black holes

EVER since Einstein's discovery of the famous equation $E=mc^2$ the direct conversion of mass into energy has remained man's most hopeful source of power Atomic fission reactors, and a possible future generation of fusion devices, manage to achieve the remarkably good efficiency (by terrestrial standards) of converting about 1% of nuclear rest mass into energy But there almost certainly lurks in the Universe a source of mass conversion with a theoretical efficiency of up to 100% This source is the famous spinning black hole

It is now generally appreciated that black holes may only be characterised by three parameters, mass, electric charge and angular momentum Other than this all black holes appear to the outside world to be identical, whatever their internal constitution Black holes with rotation possess a number of strange properties which are not shared by their nonrotating counterparts For example, suppose an inquisitive explorer were to take a trip in a rocket ship near the surface of a rotating black hole As he approached closer, he would observe that the effect of the enormously compact mass was to try to drag his rocket around with it as it rotated More and more fuel would need to be expended to resist this effect until, at a certain distance from the object, no amount of rocket power in the universe could prevent the ship from being dragged around in circles The explorer has entered a new region, the ergosphere, where it is impossible to be 'at rest' Inside the ergosphere is an event horizon, which if crossed will forbid an object to leave again Anything which arrives inside this horizon cannot by any power available prevent itself from falling towards the centre of the black hole But an object which has only ventured as far as the ergosphere can not only escape to the outside world again but actually do so with the bonus of more energy than it went in with Hence the name 'ergosphere'

The precise details of this energy-generating process were discovered by Penrose in 1969 and are based on the fact that a particle in the ergosphere is able to move along a trajectory which has negative total energy relative to a distant observer Consequently, if a particle falls into the ergosphere and breaks into two pieces such that one of these pieces moves on a negative energy trajectory, then the other piece will re-emerge with an energy which is greater than the original combined energies of both pieces, while the sacrificed piece will plunge on into the hole, the negative energy it carries thereby reducing the total mass and angular momentum of the black hole The process cannot, however, be repeated indefinitely so that the black hole disappears altogether Eventually, when the angular momentum has been reduced to zero, no further energy may be extracted in this way

A rather fanciful practical application of the Penrose process has been discussed by Misner, Thorne and Wheeler (*Gravitation*, 908, Freeman, San Francisco, 1973) An advanced civilisation could build a city around a rotating black hole, and daily dispose of its waste by dropping it in special vessels into the ergosphere, where the waste would be tipped out along a negative energy trajectory, thereby not only obligingly disposing of itself in the most effective dustbin in the Universe, but in addition supplying the re-emerging vessel with an energy equivalent of the entire waste rest mass, plus some of the rest mass of the black hole as well

As well as contributing to the solution of cosmic ecology problems, the Penrose process might serve as a mechanism for producing high velocity jets in various astrophysical situations A black hole at the centre of a galaxy could act as a repository for nearby stars, which might fragment appropriately on their way through the ergosphere, thereby imparting a very high velocity to one of the fragments, which would then emerge in the form of a jet

Strict limits on the energetics of jets formed in this way have been deduced by Wald, of the University of Maryland, in the *Astrophysical Journal* (**191**, 231, 1974) The argument used involves a simple comparison of the breakup process in ordinary special relativity with that occurring in the ergosphere of a rotating black hole

The results of this comparison are disappointing for the astrophysicist So similar are the limiting expressions in the two cases that the energy of the emitted fragment which is attainable is not greatly different whether the black hole is there or not For example, an object simply falling from rest a great distance away could initiate the ejection of a fragment with a velocity at most $1+v\sqrt{2}$ compared with the special relativistic value of v The emitted fragment can never be relativistic unless the incident body or the breakup velocity are themselves relativistic

Thus, although rotating black holes may well be responsible for triggering violent explosions at the centres of galaxies, it seems that the Penrose energy is unlikely to be making a major contribution to such events after all

Hunt the helix

from E G Richards

No sooner was the first primary structure of transfer RNA worked out, than the clover leaf model for its secondary structure was proposed This has become an article of faith for molecular biologists and all of the 60 sequences now available conform to it When the sequence of 5S RNA from *Escherichia coli* was published in 1967, several authors leapt to the challenge and published models for its secondary structure although computer investigations suggested that there were several million possibilities The favourite tack today is to devise experiments that eliminate at least some of these Kearns and Wong (*J molec Biol*, **87**, 755–774, 1974) have attempted to go one better and deduce a unique structure from the application of the nuclear magnetic resonance (NMR) method which they and others have so successfully applied to tRNA structure

Resonances in the range 12–15 p p m arise from hydrogen bonded ring N–H protons from U or G so that the number of resonances gives the number of AU and GC pairs—at least it does if GU pairs are ignored since this pair has two H-bonded ring N–H protons, but this possibility is glossed over Kearns and Wong find that at 35° C there are 28 ± 3 base pairs on this basis of which but 4 are AU As the temperature is increased about 10 resonances have melted out at 52° C to leave a 'core' structure which is stable to 62° C By 73° C a further 9 or so have gone to leave about 9 base pairs This maximal figure of 28 pairs is at variance with estimations obtained from the analysis of various optical properties which are in the range 38–44 pairs These optical methods are fraught with assumptions that are difficult to test adequately and it is reasonable to accept Kearns and Wong's result as being the more reliable

Kearns and Wong have attempted to delineate the precise base pairing scheme involved To do this they have employed explicit semi-empirical rules for calculating the precise shift expected of an AU or a GC base pair in a variety of different helical environments defined by its nearest neighbours They thus show that the structure left at 73° C gives a spectrum in close agreement with that expected of the longest and presumably most stable helical region that it is possible to form from the sequence They have gone on to list all possible helical regions in order of length and GC content and worked out the position of the resonances of each They thus show that the 'core' present at 52° C could contain the two most stable helices, H$_1$ and H$_2$ If these two are present, H$_3$–H$_{10}$ are automatically excluded since they each involve residues in common with the first two, moreover, H$_6$–H$_{10}$ give resonances that are inconsistent with the 52° C spectrum The next most stable contender is H$_{11}$ and the spectrum comprised of the H$_1$, H$_2$ and H$_{11}$ contributions is in nice agreement with the 52° C result and they conclude that the core contains these regions This core structure is of some interest in that is essentially three dimensional unlike most proposals for RNA secondary structure which can be neatly drawn on a flat page of a journal without the chain crossing itself—a restriction that would seem to be purely aesthetic in origin

The helices comprising the core rule out all but 12 of the remaining possible helices and calculation of the spectra of these eliminates all but 6 from further consideration Not all combinations of these 6 are possible but the NMR data do not allow further progress Kearns and Wong thus invoke the results of oligonucleotide binding experiments that imply that certain regions of the sequence are non-helical This serves to eliminate all but H$_{17}$ and H$_{79}$ They thus provisionally conclude that the full low temperature structure contains the five helical regions H$_1$, H$_2$, H$_{11}$, H$_{17}$, and H$_{79}$ giving a total of 28 base pairs of which 11 are AU The discrepancy in the number of AU pairs is perhaps not too serious in that the partition of the low temperature spectrum into AU and GC regions is subject to error The question may be raised as to whether this structure corresponds to the native or denatured forms of the molecule Kearns and Wong claim that their results are independent of the nature of the solvent and the mode of preparation suggests that at least some of their solutions contained a mixture of both forms It may be that the two forms are not distinguished by their technique even though it is almost certain that they have different base pairing schemes

A further question is whether their final model is compatible with other available experimental data which they do not invoke The results of limited nuclease attack have been interpreted to imply that certain pairs of regions of the structure are not hydrogen bonded to each other but, alas, it can be readily shown that Kearns and Wong's model is incompatible with these interpretations Maybe these assumptions are at fault or maybe Kearns and Wong were too simplistic in ignoring GU pairs, looped out bases and other possible structural complications Enthusiasts for these sorts of games await further developments with eager anticipation

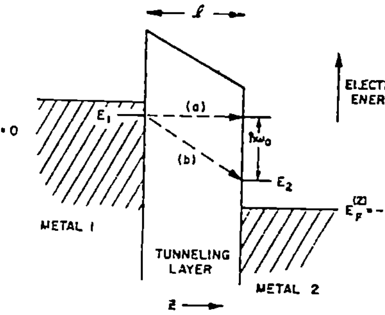
---

Solid state test tubes

from our Solid State Physics Correspondent

MANY solid state scientists have wondered whether the particular physical system with which they work (possibly a semiconductor surface or a glassy matrix) might be so sensitive to the activity of added chemicals that they could identify the chemical precisely by means of a simple electrical measurement on that solid The result would be a novel way of following reactions occurring in or on a solid—a sort of solid state test tube

One example of the fulfilment of such a wish has been developing over the last few years Giaever discovered in 1960 that the I–V characteristic of metal–insulator–metal (MIM) sandwiches was controlled by tunnelling if the insulator was only 20 Å thick He realised that the non-ohmic behaviour of the I–V characteristic happened because of the transitions of the tunnelling electron from an energy level in one metal to a different level in the other and that energy-band information —for example the size of a superconducting energy gaps—could be extracted from these I–V characteristics In fact, the I–V curve not only contained band information but also showed fine structure arising from phonon transitions and other vibrational processes (Jaklevic and Lambe, *Phys Rev Lett* **17**, 1139, 1966) In Pb–Al$_2$O$_3$–Al sandwiches an Al phonon transition can be identified and, if water is present, then the effect of OH bond vibrations are seen The reason is that the tunnelling electron, driven by the applied field, can either make a loss-free transition to a state of the same energy on the opposite side of the barrier (E_1 in the figure) or it can make a transition to a lower level, E_2, provided it can lose exactly the right amount of energy ($\hbar\omega_0$ in the figure) This energy can be transmitted to the O–H group by inelastic transfer and the transition provides an increase in the 'inelastic tunnelling current' at a potential corresponding to $\hbar\omega_0$



It must then have occurred to Lambe

and Jaklevic "If it works with the water impurity, why not with other impurities doped into the insulator lattice or even simply spotted into the surface?" Surprisingly, organic impurities did indeed couple well with the tunnelling electrons and measurements of the fine structure of the I–V curve, with very sensitive amplification and differentiation, yielded a spectrum of the bending, rocking and stretching bands of organic groups which was a near perfect analogue of the infrared or Raman spectrum with only a few special solid state effects to be accounted for Lambe and Jaklevic demonstrated this for simple volatile organic liquids such as acetone and showed that one monolayer of molecules gave suitably strong peaks but that, for sharpness, the sample must be cooled well below the temperature of liquid nitrogen (*Phys Rev*, **165**, 821, 1968) The peaks seen in the plot of d^2I/dV^2, where I is the tunnelling current for an applied voltage V, correspond very closely to the infrared absorption peaks if the voltage scale is regarded as an energy scale in eV For example, the peak of the O–H bending band appears in both measurements at precisely 0 118 eV

Simonsen and Coleman, of the University of Virginia (*Nature*, **244**, 219 1973) then developed a routine system for depositing thin layers of many organic solids by evaporation, using a special apparatus which allowed all MIM device fabrication and sample deposition to be done during one vacuum pump-down At this point, it was certainly true to say that a very original, special and useful method of vibrational spectroscopy had been added to the infrared and Raman methods A crude 'solid state test tube' had been developed which would yield a vibrational spectrum without costly infrared optics

More compounds were, of course, applied to this test cell And it must be said that, as work progressed, the doubts of the sceptics were less and less justified Within the range 0 03 to 0 55 eV (300 to 4,400 cm^{-1}) all the correct bands turn up Coleman and Hansma (*Science*, **184**, 1369, 1974) have now extended the work to some large organic compounds which can only be applied from solution The success of this 'solution doping' is a breakthrough in that very many more compounds can now be studied and, as a speculation, perhaps reacting solutions can be applied to the film and reaction products identified by the vibrational spectra Since only a monolayer is required and the MIM devices are 1 mm square, the arrangement can be operated with sub-microgram quantities of material Of course, the compounds must survive the process of drying on to an anodic Al_2O_3 film and the subsequent evaporation of a thin overlying metal film Even large molecules such as calf thymus DNA and *E coli* RNA seem, however, to survive this treatment since the tunnelling spectra exhibit the expected phosphate vibrations, ring distortions and other purine, pyrimidine and sugar group vibrations There must, in some cases, be surface reactions and, at the very least, frequency shifts because of absorptive forces and the effects of cooling These effects will then limit the delicacy with which the method can be used as an absolute sensor of bond vibrations and may also exclude the examination of easily altered compounds such as polypeptides (there is ominous silence on this class of compound)

Thus the inelastic electron tunnelling method, although still requiring much development, is probably the first of a whole range of techniques in which the behaviour of carriers in solids is used to recognise chemical characteristics of juxtaposed molecules by quantum mechanical coupling

Competition in the laboratory

from a Correspondent

IT is common knowledge that an ecologist's view of nature is coloured strongly by the particular species he or she works with Mammologists emphasise the role of aggression, ornithologists the importance of dispersal ability, and entomologists the extinction of local populations One example of this phenomenon appears in discussions of competition between species Some ecologists have argued the coexistence of two species on a single limiting resource is impossible (Gause's Exclusion Principle) and have supported this view with laboratory experiments (Gause, *The Struggle for Existence*, Dover, New York, 1958)

Others have rejected Gause's Principle as being unnecessary and have supported their claim also with laboratory experiments (Ayala, *Nature*, **224**, 1076 1969) Wallace (*Ecology*, **55**, 245, 1974), in the most extensive series to date of experiments on animal competition in the laboratory, has shown how difficult it is to subscribe to any single view of competition, even when considering an apparently similar group of species in the simplest possible conditions

Wallace has examined in detail the competition within and between eight species of *Drosophila* maintained on laboratory medium Although there is no reason to assume that the species are very different in their ecological requirements, Wallace found several different types of interactions Some pairs interfered with each other, as would be expected, but others appeared not to interact and others even to facilitate each other, permitting each to maintain higher numbers than it could alone When there was interference, it sometimes affected both species and sometimes only one of the pair

Wallace's experiments make it difficult either to accept or reject Gause's Principle Although it is probably true that two species cannot coexist on a single resource, Wallace's results clearly indicate that, in advance, it is impossible to decide what constitutes a single resource To describe the competition between several pairs of species, an individual of one species could not be replaced by a fractional equivalent of the other species That undermines the basis for much of the theory which supports Gause's Principle (MacArthur, *Geographical Ecology*, Harper and Row, New York, 1972) Certainly the construction and application of predictive models of competition between species which are based on the existence of a single limiting resource will prove to be very difficult unless competition in nature is considerably simpler than in Wallace's laboratory

Self protection in neuromuscular transmission

from our Insect Physiology Correspondent

DURING recent years there has been accumulating evidence that L-glutamate serves as the neuromuscular transmitter substance of arthropods, taking the place of acetylcholine in vertebrates in this respect The evidence has not yet convinced all authors some still maintain that glutamate is merely a non-specific agent which will depolarise muscle fibres and ultimately desensitise the receptor sites One of the unsolved problems lies in the failure of the muscles in arthropods to be affected by the L-glutamate normally present in the blood How this is prevented has remained something of a mystery

Murdock and Chapman (*J exp Biol*, **60**, 783, 1974) have made quantitative measurements of the concentration of L-glutamate in the blood plasma of the crayfish *Astacus*, the tarantula *Dugesiella* and the locust *Locusta* In the crustacean and in the spider this concentration was found to be so low that even tenfold the normal level, applied in saline, had no effect on neuromuscular transmission although higher concentrations did cause depression On the other hand the average concentration of L-glutamate in *Locusta* is sufficient to depress transmission; and slightly increased concentrations, which may occur naturally, will cause marked depolarisation. The authors discuss various possible explanations of the indifference of the locust to its circulating glutamate.

In the same issue of the journal (*ibid.*, 673) Clements and May investigate this problem in great detail in the locust *Schistocerca*. They could obtain no evidence of sequestration of glutamate by haemocytes, or of binding of glutamate by haemolymph proteins. On the other hand divalent ions, calcium and magnesium, in the haemolymph do certainly form stable complexes with amino acids and the authors estimate that the level of free glutamate is probably reduced about 25% by binding to the divalent metal ions. Both increasing the calcium concentration in the test saline, and introducing magnesium ions, made nerve–muscle preparations less sensitive to glutamate. Furthermore, these authors consistently found that isolated preparations of the retractor muscle of the claw were much more sensitive to glutamate when dissected out than when perfused in the uninjured femur. The dissected preparations studied in sections showed that the connective tissue sheath of the muscle fibres was disrupted, and ready access given to the spaces between the fibres where the neuromuscular junctions lie. They conclude that the connective tissue sheath serves as protective barrier against glutamate in the haemolymph.

Clements and May are inclined to accept the view that glutamate is normally responsible in insects for the transient depolarisation of the postsynaptic membrane that follows nervous stimulation. But, as Murdock and Chapman point out, even if it does not have this physiological role, the neuromuscular junctions must be protected from the action of unwanted glutamate.

Oscillating yield in a plastic

from Robert W. Cahn

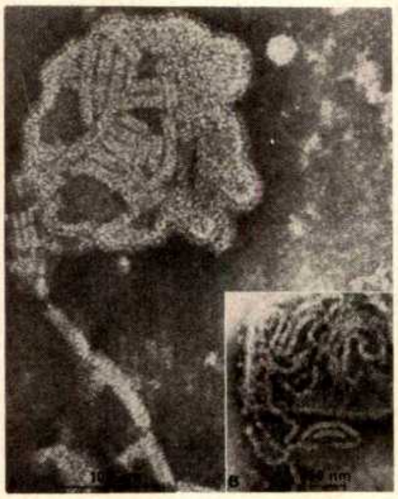
SOME years ago, a group of Russian polymer scientists (Andrianova *et al.*, *J. Polym. Sci.*, *A2*, **9**, 1919; 1971) discovered a novel form of behaviour in several polymers. The neck which forms during tensile straining of the amorphous polymer turned out to be made up of successive bands of translucent and opaque material, and the stress–strain curve showed corresponding strain oscillations. The opaque material had evidently crystallised.

This phenomenon of 'oscillating necking' has been theoretically analysed by Barenblatt in the Soviet Union (*Mekhanika Tverdogo Tela*, No. 5, 121; 1970) and to back up this analysis, Roseen of AB Atomenergi in Sweden has adopted an unusual experimental approach (*J. Mater. Sci.*, **9**, 929; 1974). He examined a tensile specimen of amorphous PETP during tensile deformation by means of an infrared Thermovision camera, which records instantaneous temperature distributions. Strips of high temperature (up to 95° C) develop in association with the opaque crystalline strips. The calibration and the resolving power of this camera are set out in some detail. It seems, therefore, that during oscillating necking, a narrow layer of crystalline material forms internally (micrographically it was shown that the surface remains amorphous). Crystallisation seems to be the result of rapid local deformation, which adiabatically heats a narrow front of polymer. The crystalline material is much less ductile than the amorphous matrix; plastic flow and its associated heat generation slows down the stress rises and the cycle repeats.

Thus, polymers may show behaviour superficially similar to the discontinuous yielding long familiar in certain alloys. This is known as the Portevin-Le Chatelier effect and is most familiar in mild steels. In essence, it is caused by the cyclic locking of dislocations by readily mobile impurity atoms (normally carbon or nitrogen). A group of dislocations breaks free, the impurity atoms catch up and lock them afresh, and the cycle repeats.

Roseen has confirmed the postulated difference in tensile behaviour between amorphous and crystalline polymer by examining the effect of intentional heat treatment of the polymer on the form of the tensile curve. Here is another unfamiliar point of similarity between metals and polymers: it is second nature to a metallurgist to examine the effect of systematic heat treatments on the mechanical behaviour of an alloy, but this is not yet a normal experiment for a polymer scientist.

One lesson from this intriguing piece of work is that it can be illuminating for a polymer scientist to know something of physical metallurgy. But it would be hubris to leave it at that. Increasingly, metallurgists have something to learn from polymer scientists, as concerns both phenomena and experimental techniques. It is time that 'polymer crystallisation' became a normal part of the syllabus of students of metallurgy and materials science.



Viruses naked and clothed

Two views of paramyxoviruses. A, Newcastle disease virus, a pathogen of chickens. The protein envelope has been broken to allow the escape of part of the nucleocapsid. B, Nucleocapsid from Sendai virus, the favourite of those who fuse cells. The nucleocapsid in both viruses consists of one long single-stranded RNA molecule around which identical protein subunits are arranged. The periodicity of the helix thus formed is visible in B. Photograph from *Virus Structure* by Robert W. Horne (Academic Press, New York and London, 1974).

Frenkel pairs in zinc selenide

from John Walker

To account for the electrical conductivity observed in some ionic solids, Frenkel suggested in 1926 that a small percentage of ions could leave their lattice sites and migrate through the crystal. The point defects so formed, the lattice vacancies and their corresponding interstitial partners, have hence been called Frenkel defects. The concept has been widely used during the past 48 years, but until recently no Frenkel defect had been observed directly. Watkins (*Phys. Rev. Lett.*, **33**, 223; 1974) has now remedied the deficiency.

After irradiating zinc selenide with 1.5 Mev electrons at a temperature of 20 K, Watkins observed a family of similar spin resonance spectra which he labelled V, V^{I}, V^{II}, V^{III}, V^{IV}. The V spectrum had previously been assigned to a hole localised on one of the four selenium neighbours to a zinc vacancy. By mechanically compressing the crystal Watkins found that he could make the hole jump freely between the four selenium atoms. (In the language of the trade, a [111] uniaxial stress makes that particular Jahn-Teller distortion energetically unfavourable and the defect flips over into one of the other ⟨111⟩ orientations.)

The other spectra are so similar to V that Watkins also assigns them to zinc vacancies. But the V^I centres do not reorient under uniaxial stress. They are therefore locked in position in the strain field of a nearby defect—the zinc atom which has been ejected to create the vacancy. It occupies the interstitial site nearest to the vacancy.

Warming the crystal above 20 K causes the interstitial zinc atom to move to a new site, behind one of the four selenium atoms surrounding the vacancy. This configuration, called V^{II}, is of lower energy than V^I because the polarisable selenium atom is between the vacancy and the interstitial. In V^{III} the interstitial lies in the ⟨100⟩ direction. No model was proposed for V^{IV}, the spectrum of which is very weak.

Directional effects observed during irradiation confirm the models. For example, when the electron beam direction is $[\bar{1}\bar{1}\bar{1}]$, more V^I defects are observed in the $[\bar{1}\bar{1}\bar{1}]$ configuration than in other ⟨111⟩ orientations.

Another interesting observation is that the isolated vacancy V is not produced linearly with electron dose. The creation rate follows a square (or perhaps a cube) law. This suggests a two-stage process, the formation of close-pair Frenkel defects being the first step.

The direct observation of vacancy–interstitial pairs in a solid is an interesting confirmation of Frenkel's original suggestion, although its impact is perhaps lessened by our present awareness of the richness and complexity of point defects created by irradiation. (An awareness due in great measure to Watkins, one might add.)

The lessons for *aficionados* of spin resonance are twofold; look for these Frenkel defects in other materials; and use the uniaxial stress technique, without which their identification in zinc selenide would have been much more difficult.

Components of the amoeba membrane

from a Correspondent

FASCINATING details of the surface structure of some primitive animal cells, amoebae and sea anemones, have recently come to light. They provide evidence for new classes of polyanions that may serve functions in primitive organisms, similar to those performed by glycoproteins containing sialic acid and the gangliosides and proteoglycans of metazoal cell surfaces.

Korn and his colleagues have been studying *Acanthamoeba castellanii*, a small free living soil amoeba that grows well on a soluble medium. About a third of the membrane is made up of a unique component that is extracted into solution with 8 M urea, or better, aqueous butanol, and is easily purified free of a non-glycosylated protein fraction. The new component contains neutral sugars, mainly mannose glucose and xylose, about 14% of fatty acids that include unusual branched chain 2-hydroxy fatty acids, and aminophosphonic acids. Of these last derivatives, the parent compound but not 1-hydroxyl-2-aminoethyl phosphonic acid are known constituents of lipids in various species of lower marine invertebrates but perversely not to any significant extent in amoebae.

Clearly the lipophosphonoglycan described by Korn and his colleagues Dearborn and Wright (*J. biol. Chem.*, **249**, 3335-3341; 1974; **249**, 3342-3346; 1974) is an integral component of the membrane and presumably is anchored into it by association of the fatty acids with the phospholipid-sterol matrix of the membrane. Brief mention is made of unpublished electron microscopic evidence by Bowers and Korn that the polar moieties of lipophosphonoglycan including phosphate groups and concanavalin A reactive sites (α-mannosyl groups) are exposed on both sides of the amoeba surface membrane.

The exact structure of this polymer is unknown. If the sugars are in normal glycosidic linkage, a core structure of galactosamine residues and aminophosphonic acids, both perhaps substituted with fatty acids and forming the attachment sites for the neutral sugars, seems to be most likely. The linkages between the constituents of the 'core' region are not known except phosphoamide bonds are excluded since these would be labile to acid hydrolysis and this is not observed.

In another publication Allen *et al.* (*J. Cell Biol.*, **60**, 26–38; 1974) describe somewhat similar material at the surface of a uninucleate, freshwater phagocytic amoeba T_1D_{13}. The only anionic group detected by Allen *et al.* at the cell surface is phosphate which accounts for more than 10% of the isolated surface membrane. Most of this phosphate (90–95%) has been isolated as a polymer in association with *neo*-inositol. Amino phosphonic acids were not detected. The large sugar content, mainly mannose rhamnose and glucose, of these plasma membranes was isolated separately in an uncharacterised fraction that seems to contain appreciable organic phosphate. It seems that these two fractions may be more closely related in the native structure, and perhaps are hydrolytic fragments produced during isolation (a part of the phosphate is very acid labile according to Allen *et al.* whereas the remaining phosphate is much more stable; the pronounced stability to acid hydrolysis of C–P bands as in phosphonic acids is a characteristic of the Korn polymer). Some structural similarity between the undegraded phosphorylated polymers of *Amoeba* T_1D_{13} and *Acanthamoeba* cannot therefore be totally excluded particularly since the analysis of Korn and his associates for lipophosphonoglycan purified from *Acanthamoeba* still leaves substantial leeway for inclusion of a polyol such as *neo*-inositol.

The clearest existing analogy to the amoeba lipophosphonoglycan is perhaps the lipopolysaccharide of certain Gram negative bacteria. Both sorts of compounds contain fatty acids including hydroxy fatty acids, and neutral and aminosugars. The bacterial polymer contains ethanolaminephosphate, the ester analogue of 2-aminoethyl phosphonate. The fraction isolated by Allen *et al.* perhaps suggests superficially a resemblance to another ubiquitous class of bacterial polymers, the teichoic acids which are based on ribitol or glycerol phosphate derivatives. Of course, it may turn out that the amoebae polymers are unique structures with no known biological precedents.

Aminophosphonic acids also turn up in phosphonoglycoproteins isolated from *Metridium dionthus* (Hilderbrand *et al., Biochemistry*, **12**, 4756–4762; 1973). These partially purified fractions contain 2-aminoethyl phosphonic acid, neutral sugars and hexosamines but apparently not significant amounts of fatty acids. The structural relationship of these polymers to the lipophosphonoglycan and in particular the method of attachment of the chains containing organic phosphorus to the polypeptide moiety will be of interest.

The prevalence of surface negatively-charged polymers of diverse structure in the lower invertebrates suggests a positive function in the ecological success of these organisms. This role may be as a mechanism providing a stable environment surrounding the cell, and may be related to the ability of the amoebae surface to absorb large quantities of various cations. This function in turn has relevance to subsequent pinocytotic events during feeding and in the uptake of nutrients under culture conditions. The existence of an anionic surface that could function as a buffering system could also form a valuable protective role against foreign cationic substances present in the surrounding medium (sea water). Alternatively, if present in the buccal cavity the phsophonate compounds may protect the organism from self dissolution by degradative enzymes spilled over from the digestive tract.

Jupiter after Pioneer: a progress report

Thomas R. McDonough

School of Electrical Engineering, Cornell University, Ithaca, New York 14850

"We now come to a much more magnificent planet, Jupiter, the largest of them all " So wrote Sir John Herschel in A Treatise on Astronomy[1] *Now, after a decade in which space programmes have concentrated on the inner planets, a spacecraft has been sent to Jupiter This article describes how the data sent back are changing our ideas about the planet*

In December 1973, Pioneer 10 became the first artefact of man to reach the environs of Jupiter In the two weeks that it spent travelling through the Jovian magnetosphere, it sent back more than 300 pictures of Jupiter, as well as measurements of magnetic fields, energetic particles, plasma, infrared and ultraviolet emissions, and micrometeoroids The spacecraft passed within 1 8R_J of the cloudtops of Jupiter (R_J, the radius of Jupiter, is 71,600 km) Preliminary reports have now been published[2–18], and here I present a progress report summarising them, describing some of the first theoretical interpretations, and suggesting some of the gaps that remain in our understanding of Jupiter

Radio occultations

The temperature structure of the Jovian atmosphere over more than 100 km of altitude has been inferred by Kliore *et al*[16] from a study of the Pioneer S-band (2,200 Mhz) signals as the spacecraft was occulted by Jupiter (see Fig 1) They found the temperature to behave quite differently from all published models, with a very strong temperature inversion at about 20 mbar pressure and 280 K temperature, which may be explained by absorption of solar radiation by dust[16,19] They also expect to derive an electron-density profile of the Jovian ionosphere, but it is complicated by multipath propagation[16] This will be a welcome addition to the many ionosphere models that have lacked any data by which to be tested

Pioneer's trajectory was designed so that it would be occulted by the Jovian satellite Io It had been suspected for several years that Io might have an atmosphere, because Io is sometimes brighter after passing behind Jupiter as if snow had fallen during the passage through Jupiter's shadow[20–22] Recently, evidence of atomic sodium gas at Io has been found by R A Brown[18,23] Analysing the Io occultation, the Kliore group discovered that Io has an ionosphere, with a peak density of 6×10^4 cm^{-3} at an altitude of ~100 km (see Fig 2) They estimated theoretically that this could imply a neutral atmosphere with a density at the Io surface of 10^{-8} to 10^{-10} bar They propose that Io has a new kind of ionosphere, reaching from the surface up to 700 km

Ultraviolet photometer

A year ago it was predicted that if any of the Galilean satellites have atmospheres, gases escaping from them could form large toroidal rings around the planet[24,25] Judge and Carlson[11] using Pioneer's ultraviolet photometer, found Lyman-α emissions (attributed to atomic hydrogen) of several hundred rayleighs intensity from the equatorial plane of Jupiter at a time when neither Jupiter nor its satellites were in the field of view, and they tentatively interpret the radiation as originating in such a toroid They also made the surprising discovery that Io seems to have a Lyman-α brightness of 10^4 rayleighs, corresponding to a column excitation rate of 10^{10} photons cm^{-2} s^{-1}, an order of magnitude brighter than Jupiter at this wavelength Although such Lyman-α radiation is usually the result of scattering of solar ultraviolet by atomic hydrogen, they

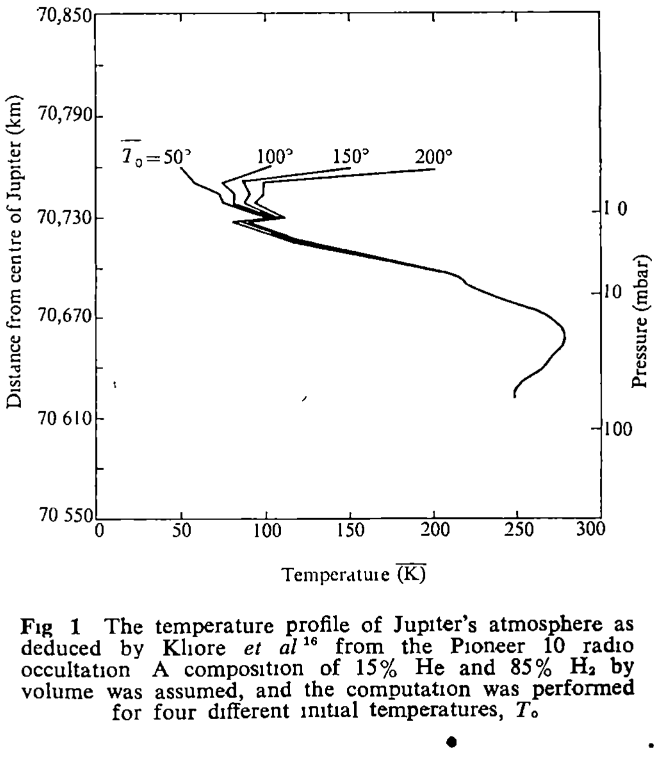

Fig 1 The temperature profile of Jupiter's atmosphere as deduced by Kliore *et al*[16] from the Pioneer 10 radio occultation A composition of 15% He and 85% H_2 by volume was assumed, and the computation was performed for four different initial temperatures, T_0

suggest that this extraordinary brightness may be due to auroras on Io

The presence of hydrogen on Jupiter has long been known, but helium had never been detected until Pioneer's arrival Judge and Carlson's photometer detected ~15 rayleighs of the He 584 Å emission line Their Lyman-α (1216 Å) channel measured a Jovian brightness of about 10^3 rayleighs, attributed to the glow of atomic hydrogen, a lower value than sounding-rocket measurements of Rottman *et al*[26] Derivation of the He/H ratio from the ultraviolet measurements awaits detailed model-atmosphere calculations, but the 1971 model of Carlson and Judge[27] suggests, for the observed helium emission, a value of He/H_2 ~ 50% in the lower atmosphere

Infrared radiometer

Chase *et al*[10] (G Munch, principal investigator) mapped Jupiter at wavelengths of 20 and 40 μm, with the Pioneer infrared radiometer The 20 μm channel contains the rotational component of the H_2 spectrum, and the 40 μm one the translational component The latter is dependent on the partial pressure of He, so for the first time it is possible to measure the He/H_2 ratio on Jupiter, although the ratio is somewhat model-dependent Theoretical estimates of the abundance of Jovian helium have ranged from the cosmic abundance, in which He/H~10% by number, up to a model in which helium is the major constituent and hydrogen a minor one[28] This abundance is an important input to models of the Jovian interior and atmosphere The Chase group calculates He/H_2 ratios (by number) from 0 6 to 0 8, that is, He/H is from 0 3 to 0 4, somewhat higher than most theoreticians expected, and higher than the values emerging from stellar occultation studies (L Wasserman, private communication)

Measured infrared brightness temperatures ranged from 115 K to 145 K, and seem to be roughly correlated with the visible belts and zones For the first time ever, the rear of Jupiter was observed, and, as expected, the planet was found to radiate as much infrared from its dark side as from the front Chase *et al* compute that Jupiter radiates about twice as much energy as it receives from the Sun, a result somewhat smaller than the aircraft measurements of Aumann *et al*[29] but removing at last any uncertainty about the far-side emission Jupiter radiates like a feeble star

Imaging photopolarimeter and television

The imaging photopolarimeter of Gehrels *et al*[12] contained a 2 5 cm telescope which made maps of Jupiter in blue and red light, polarised and depolarised, as the spacecraft spun Some measurements were also made of the Galilean satellites The most striking early results were the hundreds of photographs that resulted from the spin-scans of the planet, giving higher resolution pictures of the planet than had previously been possible Four "small" (4,000 km) bright spots have been observed, as have several bright swirls Two of the light-coloured zones of Jupiter show a distinct wave pattern The border of the Great Red Spot is dark, and sharp to the limit of resolution

Gehrels *et al* found that the blue polarisation varied from several per cent at the centre of the disk to ~40% at the poles These high polarisations are believed to be due to Rayleigh scattering, and Gehrels *et al* expect to use them to measure the amount of gas above the clouds It may be possible to derive the size, shape, and refractive index of the cloud particles now that we have measurements over the large phase angles impossible to obtain from Earth

The magnetometer

The first surprise from Pioneer was the detection of Jupiter's influence on fields and particles well before the expected time It is known that the solar wind is deflected by the Earth's magnetic field, forming a bow shock, and straightforward scaling implied that the Jovian bow shock should occur at about 50 R_J from the planet[30] But the helium vector magnetometer of Smith *et al*[5] detected the bow shock at 108 R_J The magnetopause was observed at 96 R_J, and the magnetic field remained near 5×10^{-5} gauss from there to about 50 R_J with frequent irregular dips to values near 1×10^{-5} gauss

After 25 R_J, the field began to appear more dipolar Using the field values measured when close to the planet, the experimenters estimate the dipole moment of Jupiter to be 4 0 gauss R_J^3 The dipole is tilted by ~15° and displaced by about 0 2 R_J from the centre of the planet, which implies surface fields from ~2 to ~12 gauss if quadrupole terms are negligible This is a more tilted and slightly weaker field than had been deduced from terrestrial measurements of the decametric noise bursts, but is not in serious disagreement The field is upside-down with respect to the Earth's which was also expected

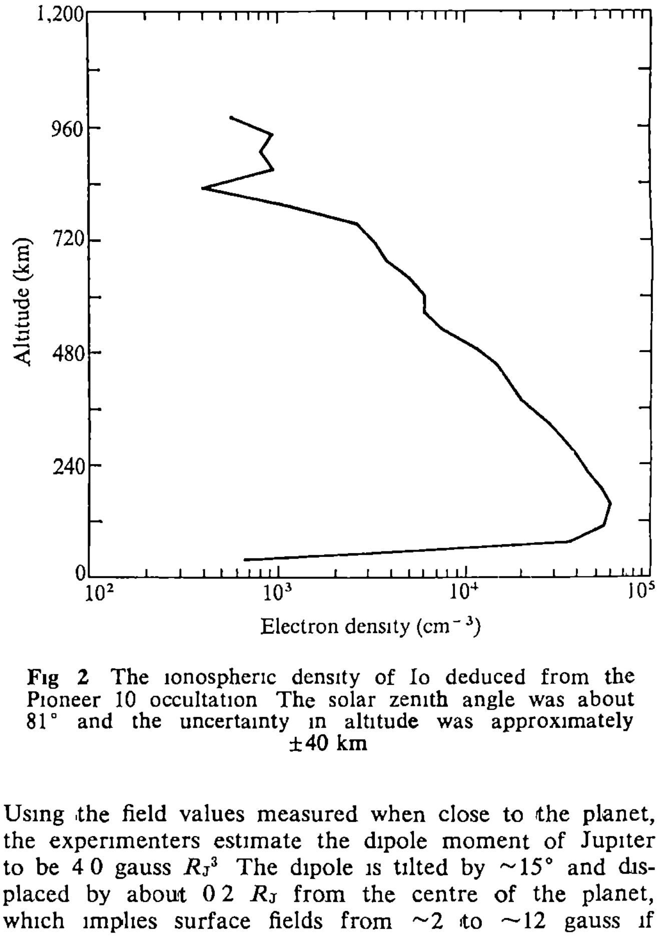

Fig 2 The ionospheric density of Io deduced from the Pioneer 10 occultation The solar zenith angle was about 81° and the uncertainty in altitude was approximately ±40 km

Smith *et al* suggest that their observations could be explained by a disk-like magnetosphere, radically different from the Earth's, although they do not rule out the possibility of a thick magnetosphere The reason for such a non-spherical 'magnetodisk' may be that the density and temperature of the magnetospheric plasma are so great that the magnetic field cannot contain the plasma at distances larger than about 20 R_J Inside that distance, it would resemble the Earth's magnetosphere, and outside, plasma would be thrown out, forming a magnetodisk something like the solar wind, with a spiral magnetic field, but which would also have some of the properties of the Earth's magnetotail, such as a neutral sheet

Plasma analyser and energetic particle detectors

The plasma analyser of Wolfe *et al*[4] measured proton spectra from 100 eV to 18 keV, electron spectra from 1 to 500 eV, charged-particle fluxes from 1×10^2 to 3×10^9 $\text{cm}^{-2}\ \text{s}^{-1}$, and the plasma flow velocity Their measurements of the bow shock correlated well with the magnetometer observations They found that the electron energy tended to peak at about 3 eV within the magnetosphere The ion energies were too small to register but the authors suggest that the outer magnetosphere of Jupiter is in a high-beta regime—in other words, the thermal energy dominates the magnetic energy

A most surprising result of the plasma analyser measurements was that the spacecraft apparently passed through the magnetosheath twice while approaching Jupiter, as if there were not one but two magnetospheric bow shocks The first occurred at about 100 R_J, and the second at about 50 R_J As the spacecraft left Jupiter three more shocks were observed Wolfe *et al* suspect that the solar-wind pressure may have fluctuated, causing the bow-shock distance to vary, but it has also been suggested that this could be an effect of the eccentricity and tilt of the Jovian magnetic dipole One suspects that if the plasma is ejected into the magnetodisk from near the magnetic equator, the plasma may create giant waves in the magnetodisk, so the spacecraft may have passed through several troughs and crests of a wavy magnetodisk

The flux of relativistic ($\gtrsim 3$ MeV) electrons, of protons above 0 5 MeV, and of 1 MeV per nucleon helium nuclei were measured by Simpson *et al*[6] with the charged-particle detector, and electrons above 70 keV were observed by Van Allen *et al*[7] with the Geiger-tube telescope The cosmic-ray telescope results reported by Trainor *et al*[8] (F B McDonald, principal investigator) provided data on high-energy electrons, protons, and helium nuclei, including high-intensity flux measurements of protons from 0 5 to 21 MeV and electrons from 0 1 to 1 MeV The trapped radiation detector of Fillius and McIlwain[9] measured fluxes, energy spectra, and angular distributions of 100 keV to 50 MeV electrons and of protons above 70 MeV

One month before encounter, the Simpson group detected bursts two days long of electrons up to 30 MeV in energy, analogous to precursors of the terrestrial magnetosphere but far more energetic The flux of relativistic electrons[6] reached $\sim 5 \times 10^8$ $\text{cm}^{-2}\ \text{s}^{-1}$ near closest approach (2 8 R_J), which was about an order of magnitude greater than the upper limit of the Jupiter Radiation Belt Workshop[31] The Workshop electron model was based to a large extent on terrestrial observations of the radio emissions of Jovian relativistic electrons, and the weaker magnetic field found by Jupiter accounts in part for the underestimate of the electron flux For protons, there were no such observational data prior to Pioneer, yet the observed[6] peak flux of $\sim 4 \times 10^6$ protons $\text{cm}^{-2}\ \text{s}^{-1}$ was near the Workshop nominal prediction The proton flux falls off within $\sim 3\ 5$ R_J, however, which was unexpected

All four groups found the particles to be highly concentrated near the magnetic equatorial plane from ~20 to ~100 R_J, and remarkably different from the terrestrial magnetosphere On the outward journey through the magnetodisk, bursts of energetic electrons and protons were found with time scales of minutes, which had great directional anisotropies[8] The experimenters noted similarities with phenomena of the Earth's magnetotail, which are understandable if the Jovian magnetic field is confined to a disk outside ~20 R_J, since one would expect the field to be stretched out in the disk in a manner similar to a magnetotail They found that the particles are trapped in a manner similar to the Earth's magnetosphere only for distances within about 20 R_J

Mead and Hess[32] had proposed that the Galilean satellites could sweep up some of the energetic particles, and Pioneer fluxes did indeed dip while passing the orbits of Europa, Io, and possibly Ganymede, but not that of the most distant and theoretically least influential, Callisto[7-9] Perhaps the proton decrease within 3 5 R_J is related to sweeping-up by the small satellite Amalthea at 2 5 R_J, which was also suggested by Mead and Hess[6 32]

Asteroid and meteoroid detectors

Two instruments on Pioneer detected micrometeoroid and larger particles The photomultiplier telescopes of Soberman et al[13] detected particles ranging from 35 μm to 10 cm at distances from 2 to 3 5 AU The pressure cells of Kinard *et al*[14] detected particles of mass $\sim 10^{-9}$ g, and showed that the asteroid belt had no more of these particles than the regions before and after the belt As was expected, the number of particle detections by the latter instrument rose dramatically when it arrived at Jupiter Kinard *et al* do not yet know whether the particles are interplanetary ones attracted by Jupiter, or particles actually orbiting the planet

Trajectory analysis and spacecraft survival

Anderson *et al*[15] have studied the Doppler shifts of the S-band transmissions of Pioneer 10 to determine the spacecraft trajectory with great precision They expect to be able to measure the masses of the Galilean satellites to 1% by studying the perturbations they cause on the trajectory They have already found that Io is about 20% heavier than previously thought, making its density 3 5 g cm^{-3}, slightly denser than our own Moon, which places an important constraint on chemical models of its interior If the pre-Pioneer densities of the other Galilean satellites[21] are approximately correct, this new Io density implies that the density of Galileans decreases with distance from the planet, analogous to the general behaviour of planet densities with distance from the Sun, which is a clue to the origin and evolution of the Solar System

Anderson *et al* also expect to measure several of the higher harmonics of the Jovian gravitational field, giving information on the distribution of mass within Jupiter obtainable in no other way This should tell us something about whether Jupiter has a core, and what its composition is, and whether there is an internal mass-asymmetry related to the eccentric magnetic field

An important datum provided by Pioneer 10 was that it survived passage through the asteroid belt and the Jovian magnetosphere It received an integrated dose of 2×10^5 rads from electrons and 5×10^4 rads from protons greater than 30 MeV, where 500 rads is a lethal human dose[17] This was very nearly the maximum dose that the spacecraft could withstand In addition to that, it is known that a spacecraft in a Van Allen belt may charge up to potentials large enough to damage the instruments[33], and it has been suggested that this charging phenomenon could be a danger to Pioneer (N M Brice, private communication, and unpublished work of F L Scarf and R W Fredericks) The fact that the spacecraft survived this danger is consistent with the presence of an unexpectedly large density of magnetospheric plasma, whose presence would tend to nullify the charging caused by energetic particles Fillius and McIlwain[9], however, do not rule out the possibility of serious spacecraft charging, which, they point out, may bias charged-particle measurements

The future

Pioneer 10 has confirmed as inescapable the fact that Jupiter radiates more energy than it receives from the Sun The source of this radiation is a major theoretical problem Models of the Jovian interior must not only explain this, but must also explain the eccentricity of the magnetic field and the values of the gravitational parameters of the planet The observed He/H abundance will serve as a constraint on atmospheric and interior models

Jovian meteorology is much more complex than had been supposed, and new atmospheric models must be constructed, probably incorporating dust The multitude of theories of the Great Red Spot may at last be tested against the new data

It is up to theoreticians to understand why the magnetosphere of Jupiter proved to be so utterly different from what we had expected At this early date, it seems to be due to unexpectedly large amounts of magnetospheric plasma, so it may be that the rate of plasma input to the magnetosphere is much larger than has been estimated or that the storage time is much greater

The distribution of energetic electron and proton fluxes can now be tested against existing theories of particle-diffusion mechanisms (refs 34–36 and unpublished work of S A Jacques and L Davis jun) Interpretation of the decimetric radiation has been complicated by the fact that the synchrotron emission is a function of both the electron energy spectrum and the magnetic field Now that we know the strength and structure of the magnetic field, we can use the theory of synchrotron radiation to extract the relativistic electron energy spectra from Earth based radio-telescope observations of the decimetric noise If the deduced energy spectra are consistent with the Pioneer measurements, this will verify the calibration of both the energetic electron sensors and the magnetometer We can then use past and future earthbound observations of the decimetric noise to measure the relativistic electron energy spectra as a function of time and position in the Jovian Van Allen belts

Io is now an even more intriguing object than before It has an atmosphere, an ionosphere, a torus, sodium atoms, brightness fluctuations, possible auroras, and it appears to control the decametric noise bursts Theories of the interaction of Io with the Jovian magnetic field, designed to explain the radio bursts, must now incorporate a conducting ionosphere It has even been suggested that Io may be the source of the Van Allen belt electrons[18]

Pioneer 10 is not only the first spacecraft to reach Jupiter, it will be the first to leave the Solar System It carries on it the famous plaque bearing a drawing of a man and woman, and telling, in the language of mathematical physics, the location of its home planet[37]

As Pioneer 10 leaves the Solar System, its near-twin, Pioneer 11, is in the asteroid belt, and is scheduled to arrive at Jupiter next December At present, NASA has decided to give it a trajectory which would take it to Saturn in 1979, but which might expose it to dangerous radiation levels at Jupiter[38] Two Mariner spacecraft are scheduled to be launched in 1977 to visit Jupiter and Saturn

Many of the discoveries of Pioneer 10 can be economically described by the statement that Jupiter resembles the Sun more than the Earth In composition, energy production, radio noise, differential rotation, field eccentricity, and the interaction of its plasma with its magnetic field, Jupiter displays truly stellar qualities

This paper is dedicated to the memory of Professor Neil M Brice, whose recent tragic death withdrew from the world a brilliant scientist, a wonderful human being, and a very good friend Whatever growth as a scientist I may have attained in the last few years, I owe largely to his encouragement, stimulation, enthusiasm, energy and constructive criticism

I thank the following for useful conversations Professors P Gierasch, M Harwit, and C Sagan, Drs S Soter and W E Swartz, Messrs B Gross, R Reed, and Dr L Wasserman, of Cornell University, Professor T Gehrels of the University of Arizona, Dr A Kliore of the Jet Propulsion Laboratory, Dr J D Mihalov of the NASA Ames Research Center, Dr T D Parkinson of Kitt Peak National Observatory, and Dr J A Simpson of the University of Chicago This research was sponsored by the NASA Physics and Astronomy Program and the National Science Foundation Atmospheric Sciences Section I thank Dr Kliore for permission to use the radio-occulation curves of ref 16

Trapped xenon in meteorites

D. D. Sabu,
Department of Chemistry, Grambling College, Grambling, Louisiana 71254

E. W. Hennecke, & O. K. Manuel
Nuclear Division, Department of Chemistry, University of Missouri, Rolla, Missouri 65401

Xenon in meteorites can be resolved into a mixture of component X and trapped xenon with the following composition, ^{124}Xe ^{126}Xe ^{128}Xe ^{130}Xe ^{131}Xe ^{132}Xe ^{134}Xe ^{136}Xe $= 0.0276$ 0.0248 0.501 1.00 5.04 6.19 2.31 1.90 *This trapped meteoritic xenon is distinct from xenon trapped in the average carbonaceous chondrite which is shown to represent the average composition of the total xenon in meteorites containing various mixtures of component X and trapped meteoritic xenon*

IN 1960, Reynolds[1] reported the discovery of radiogenic ^{129}Xe, the decay product of extinct ^{129}I, in the Richardton chondrite. He also noted a general anomaly pattern across the isotopes of xenon in the Richardton meteorite, and later that year he reported[2] a similar isotopic anomaly pattern in xenon released from the Murray carbonaceous chondite. Since Murray contained over 40 times more xenon than Richardton, but less cosmogenic noble gas isotopes than Richardton, Reynolds[2] concluded that the general anomaly pattern was characteristic of primordial xenon.

Following Reynolds[1,2] discovery of general isotopic anomalies in meteoritic xenon, there were other attempts to determine accurately the isotopic composition of xenon trapped in meteorites[3–5]. Apart from a component similar to atmospheric xenon which is released at low extraction temperatures and is presumably due to contamination of meteorite surfaces by the atmosphere, these studies[1–5] showed that the xenon trapped in average carbonaceous chondrites (AVCC Xe) may be a mixture of fractionated atmospheric-type xenon plus a fission component. But, the concept of AVCC Xe as primordial, when defined as a mixture of two components, was unclear, and this concept has become increasingly vague as the results of stepwise heating experiments on different carbonaceous chondrites in several laboratories[6–13] demonstrate convincingly that the two components of AVCC xenon are inhomogeneously mixed.

Accurate measurements of the isotopic composition of xenon from the Sun might help elucidate the nature of primordial xenon in our Solar System, and a component of solar xenon has recently been identified in the Pesyanoe meteorite[14] and in lunar soil[15–20]. The general features of this solar xenon can be related to atmospheric xenon by isotopic mass fractionation, although certain xenon isotopes consistently deviate from the general fractionation pattern[15–22]. It has been suggested that deviations from the general isotopic fractionation pattern are due to radiogenic ^{129}Xe in the atmosphere[18,22], to excess ^{131}Xe and ^{132}Xe in the atmosphere[18], to fissiogenic ^{134}Xe and ^{136}Xe in lunar fines[16–18,20–22], and to either an excess of ^{126}Xe, or a deficiency of ^{124}Xe, in solar xenon as a result of nuclear reactions[20,23]. Eberhardt *et al.*[16] have also suggested the possibility that fractionation might not be responsible for major differences in the isotopic composition of solar and terrestrial xenon, but that these two types of xenon might originate from different nucleosyntheses.

We have noted[24] that the xenon released from carbonaceous chondrites at ≈600°–1,000° C contains an excess of the proton-rich isotopes, $^{124-128}$Xe, and the neutron-rich isotopes, $^{131-136}$Xe. This observation suggests that meteoritic xenon consists of two isotopically distinct components whose presence cannot be explained by nuclear or fractionation processes within the meteorites. The meteoritic xenon component which is enriched in both the light and the heavy isotopes relative to ^{130}Xe was referred to as X, but the nature of the other meteoritic xenon component was not clearly defined. In this report the available data on xenon in carbonaceous chondrites, in lunar fines, and in the Earth's atmosphere are examined to seek a better understanding of the nature of these two components of meteoritic xenon.

General isotopic anomaly patterns of xenon

The isotopic composition of xenon in the three major reservoirs of xenon which have been studied, the Earth's atmosphere, meteorites, and lunar soil is presented in Table 1. The isotope ^{129}Xe is excluded because it is produced[1] in the early Solar System by the decay of primordial ^{129}I.

In Table 1, the nonradiogenic and nonspallogenic isotopes of xenon in lunar fines are used to represent the composition of solar xenon. The results from various laboratories are shown because estimates on the composition of xenon in lunar fines differ significantly between them, and there are differing opinions on the actual isotopic composition of xenon in the solar wind. These various estimates of solar xenon do however show a systematic relationship which suggests that they may be related by mass-dependent fractionation[20].

Two estimates for the composition of xenon in meteorites are represented in Table 1 by AVCC and WAVCC. The values for AVCC are an average of the estimate of trapped meteoritic xenon based on seven meteorites analysed by Marti[4] and three

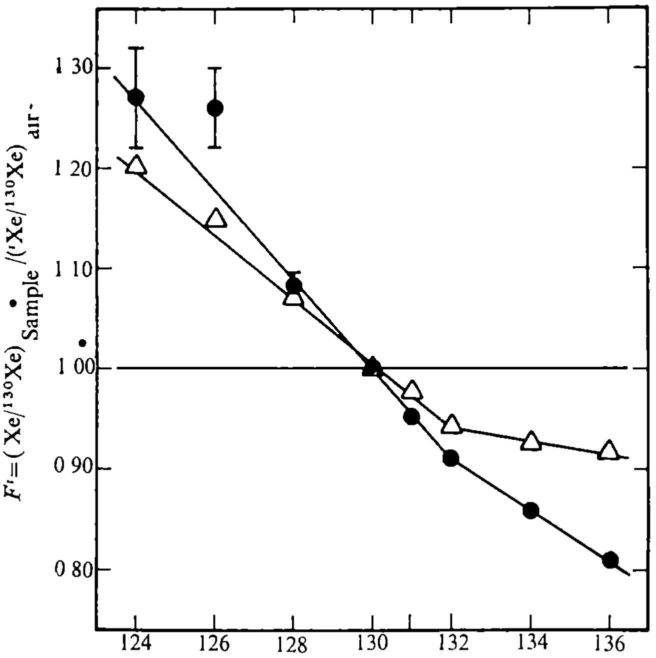

Fig 1 A comparison of AVCC xenon[4,5] (△) and solar xenon[19] (●) with xenon in the Earth's atmosphere[25]. The break in the lines at ^{132}Xe indicates that neither of these two forms of extraterrestrial xenon can be related to atmospheric xenon by mass-dependent fractionation.

carbonaceous chondrites analysed by Eugster *et al*[5]. The values shown for WAVCC represent a weighted average for approximately 75 analyses in different laboratories on a total of 35 carbonaceous and gas-rich meteorites, as listed in Table 5 of Mazor *et al*[26]. These results were weighted according to the xenon content of the meteorites. The abundances of the two light xenon isotopes, ^{124}Xe and ^{126}Xe, are not shown in WAVCC as there are no data on these isotopes for many of the analyses[26]. The lower abundance of the heavy xenon isotopes in WAVCC than in AVCC indicates that the relative abundance of the heavy isotopes is lower in xenon-rich meteorites than in average carbonaceous chondrites. Atmospheric xenon is represented in Table 1 by the widely quoted analysis by Nier[25] and by a recent analysis by Podosek *et al*[18].

To compare the composition of xenon in these three reservoirs, we used the method of Canalas *et al*[27], in which the abundance of each isotope of mass number, i, is compared with its atmospheric abundance by the factor, F^i, defined as follows

$$F^i = ({}^{i}\mathrm{Xe}/{}^{130}\mathrm{Xe})_{\mathrm{sample}}/({}^{i}\mathrm{Xe}/{}^{130}\mathrm{Xe})_{\mathrm{air}} \qquad (1)$$

The values of F^i for solar and AVCC xenon are plotted against mass number, i, in Fig 1. For this comparison we have used Nier's value for atmospheric xenon[25] and Kaiser's value for solar xenon[19]. The latter was selected because it represents an extreme of the estimates for solar xenon and has been earlier depicted as solar xenon with the lowest fission component.

Several investigators[14-17] have suggested that solar xenon and AVCC xenon are identical, except for the presence of excess $^{132-136}$Xe in the latter. Atmospheric xenon and AVCC xenon can be related by mass-dependent fractionation[1-5], except for the presence of excess $^{132-136}$Xe in the latter. Thus, the view of solar and AVCC xenon expressed by these investigators[14-17] suggests that atmospheric and solar xenon are directly related by fractionation. Kaiser[19] has recently interpreted his results on xenon in Luna 16 as evidence that atmospheric xenon is, in fact, fractionated solar xenon. But, as can be seen in Fig 1, even for the extreme estimate of solar xenon as given by Kaiser[19], there is steeper fractionation across the light isotopes, $^{124-131}$Xe, than across the heavy isotopes, $^{132-136}$Xe. The break in the fractionation patterns for both AVCC and solar xenon at ^{132}Xe clearly shows that neither of these two reservoirs of extraterrestrial xenon can be related to atmospheric xenon by simple mass-dependent fractionation.

Component X and trapped meteoritic xenon

Reynolds and Turner[6] have reported the presence of excess heavy xenon isotopes in the gas released from the Renazzo carbonaceous chondrite at 700°–1,000° C. Stepwise heating experiments on other carbonaceous chondrites in several laboratories[7-13] confirmed this anomaly. We have reported[24] that the results of stepwise heating experiments showed an enrichment of ^{124}Xe in the same temperature fractions which contained excess ^{136}Xe. The correlation observed between light and heavy isotopes could not be explained by any of the previously proposed mechanisms, and we concluded that the observed anomaly pattern was caused by the release of an isotopically distinct component of xenon, referred to as component X, which had been incorporated into the meteorites.

Phinney's[13] analyses for xenon released by stepwise heating of carbonaceous chondrites for the temperature fractions showing the largest enrichment of ^{136}Xe are listed in Table 2 together with the results of stepwise heating experiments discussed in our earlier report[24].

The correlation between the enrichment of the light isotopes, ^{124}Xe and ^{126}Xe, and the enrichment of the heaviest isotope, ^{136}Xe, in the xenon released by stepwise heating can be seen in Fig 2, where ^{124}Xe/^{130}Xe and ^{126}Xe/^{130}Xe are plotted against ^{136}Xe/^{130}Xe. Estimates of solar, atmospheric, and meteoritic xenon from Table 1 are shown for comparison. As can be seen from Fig 2, the data of Phinney[13] agree with the correlation reported earlier[24]. The abundances of ^{124}Xe and ^{126}Xe have not been corrected for cosmic-ray induced spallation reactions, which may partially account for the scatter of data points from the correlation lines.

The dashed line in Fig 2 shows the relationship expected from diffusive fractionation[28], and the failure of solar xenon to lie on the fractionation line passing through atmospheric xenon is understood in terms of the relationship shown in Fig 1. The solid line connecting atmospheric and solar xenon defines the isotopic composition of xenon which would be produced by mixing components from these two xenon reservoirs. This 'mixing' line approximately parallels the fractionation relationship. If AVCC Xe really represents an average of the total xenon in meteorites, then the composition of trapped meteoritic xenon, when corrected for the presence of component X, would be

Table 2 Anomalous xenon released in stepwise heating of the carbonaceous chondrites

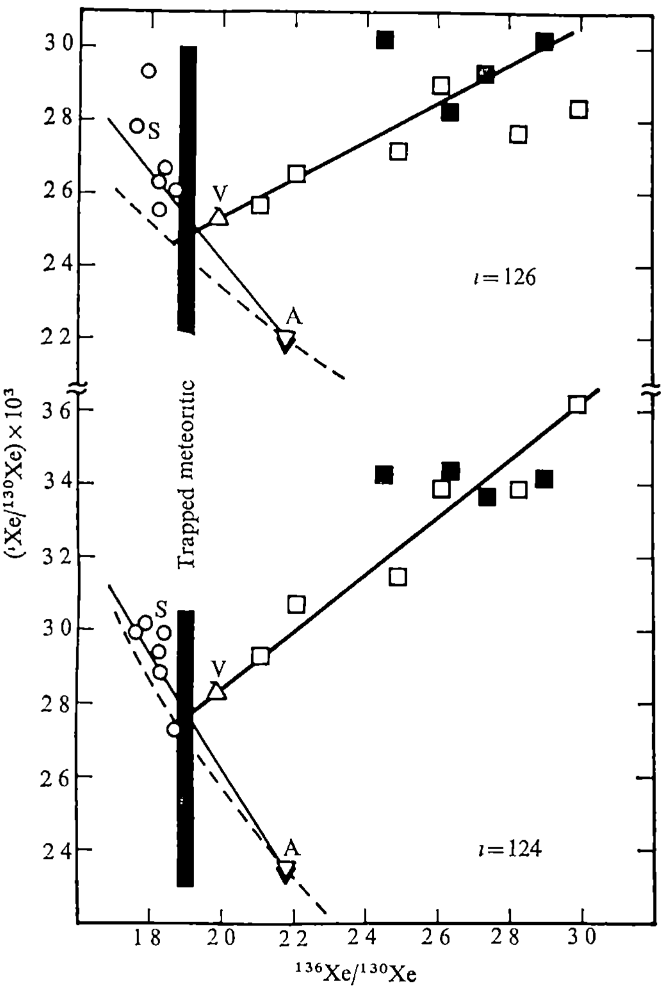

Fig 2 The correlations of $^{124}Xe/^{130}Xe$ and $^{126}Xe/^{130}Xe$ with $^{136}Xe/^{130}Xe$ in the xenon released by stepwise heating of carbonaceous chondrites The correlations between these xenon isotope ratios are shown by the heavy lines ■ Represents recent stepwise heating data by Phinney[13] The symbols S, V, A are shown above solar, AVCC, and atmospheric xenon, respectively The dashed line passing through atmospheric xenon shows the isotope compositions expected from diffusive fractionation, and the solid line passing through atmospheric and solar xenon show the isotopic compositions expected from mixing these two types of xenon

expected to lie to the left of AVCC Xe on the correlation lines shown in Fig 2 Likewise, the subtraction of component X from the xenon released at each extraction temperature might leave a common trapped meteoritic xenon component Since the other two known reservoirs of xenon are solar and atmospheric, a suitable choice for trapped meteoritic xenon can be characterised by the intersections of the correlation lines with the 'mixing' line or the fractionation line The darkened column labelled trapped meteoritic in Fig 2 represents these intersections Until the isotopic composition of solar xenon is sufficiently well established to indicate clearly the relationship between solar and atmospheric xenon, a decision on which intersection represents 'trapped meteoritic' xenon would be arbitary Since these three reservoirs of xenon are probably genetically related, though not necessarily by a diffusive fractionation relationship, we will postulate a simple linear relationship between atmospheric and solar xenon to see if meteoritic xenon can be resolved into a mixture of component X and a self-consistent composition for trapped meteoritic xenon

The observed correlations between the other nonradiogenic xenon isotopes released in the stepwise heating of carbonaceous chondrites are shown in Fig 3, together with the 'mixing' line between solar and atmospheric xenon All the xenon isotope data from Table 1 and Table 2 for i = 128–136 are shown in Fig 3, except for the ratio, $^{128}Xe/^{130}Xe$, in the xenon released from the Allende meteorite at 1,000° C The unusually high value for this ratio, indicated by the arrow in Fig 3, is attributed to neutron-capture reactions on ^{127}I in this meteorite Firemen *et al*[29] and Manuel *et al*[12] have reported an excess of certain noble gas isotopes in Allende as a result of neutron-capture reactions on halogens

From Fig 3 it appears that the points of intersection of the correlation lines and the 'mixing' lines define a self-consistent composition for trapped meteoritic xenon, and this composition is also consistent with the trapped xenon shown in Fig 2 The isotopic composition of trapped meteoritic xenon defined by these intersections is ^{124}Xe ^{126}Xe ^{128}Xe ^{130}Xe ^{131}Xe ^{132}Xe ^{134}Xe ^{136}Xe = 0 0276 0 0248 0 501 1 00 5 04 6 19 2 31 1 90 The scatter of data points about the correlation lines in Fig 3 may be due to variations in the compositions of trapped meteoritic xenon If the trapped meteoritic xenon lies along the 'mixing' line, as would be expected if meteoritic xenon has been acted on by the same process responsible for the relationship between atmospheric and solar xenon, then this might account for the smallest scatter of data points along the correlation line for i = 134 For this isotope, the slope of the 'mixing' line and the slope of the correlation line are most nearly equal

It should be noted from Fig 3 that, relative to ^{130}Xe, all the other xenon isotopes are enriched in component X when compared with their abundance in trapped meteoritic xenon We have considered[24] possible origins for component X earlier and shall now discuss the relationship between AVCC xenon, trapped meteoritic xenon, and component X

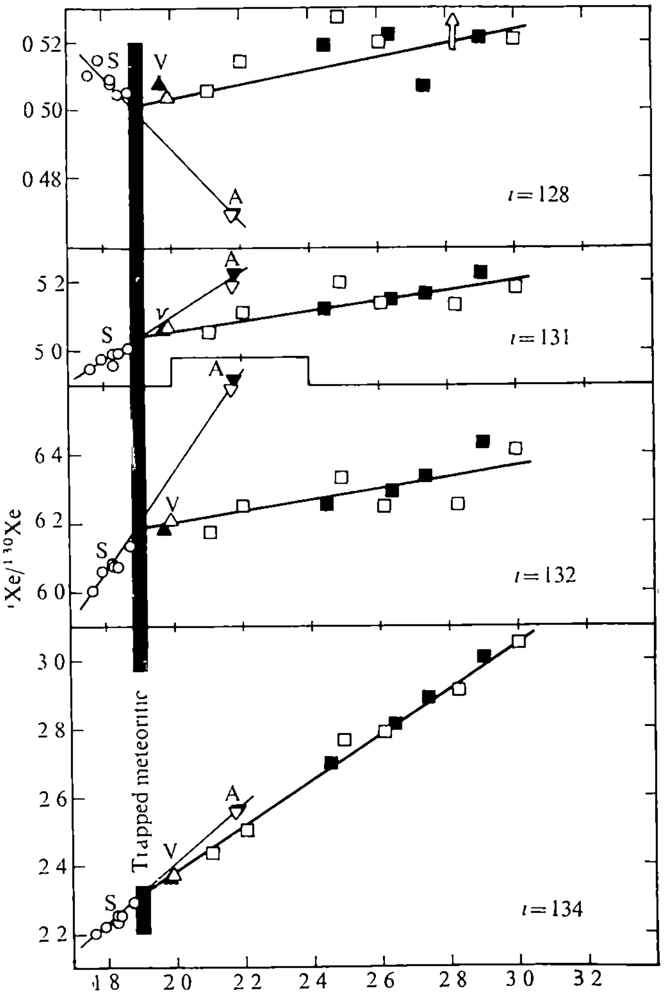

Fig 3 The correlation of other xenon isotope ratios with $^{136}Xe/^{130}Xe$ in the xenon released by stepwise heating of carbonaceous chondrites The lines and symbols are as defined for Fig 2 except that both AVCC and WAVCC are shown below the symbol V

AVCC xenon

Mazor *et al*[26] have shown the results of approximately 75 analyses for meteoritic xenon from several laboratories These results are for total xenon and do not include data on ^{124}Xe and ^{126}Xe for most of the meteorites No data on ^{130}Xe are given for four of the analyses Thus, it is not possible to determine whether the total xenon in these meteorites shows a correlation between an enrichment of the light isotopes and an enrichment of the heavy isotopes, as shown in Fig 2 for stepwise heating experiments

But, even in total melt experiments, we find variations in the relative abundances of the heavy xenon isotopes as observed for stepwise heating experiments This correlation of excess ^{136}Xe with excess ^{134}Xe in about 70 total melt analyses of the xenon in 35 different meteorites is shown in Fig 4 The dashed lines indicate the area of uncertainty for the correlation which would result if points on the solid correlation line had an uncertainty of $\pm 1\%$ This degree of uncertainty is typical of the xenon isotope measurements, and this is shown for a symbolic data point in the lower right of Fig 2 The isotopic compositions given in Table 1 for AVCC and WAVCC are shown in Fig 4 The fact that these lie near the middle of the graph, which is heavily populated with data points representing total meteoritic xenon, demonstrates that AVCC and WAVCC satisfactorily describe the average isotopic abundances of ^{130}Xe, ^{134}Xe and ^{136}Xe in total meteoritic xenon

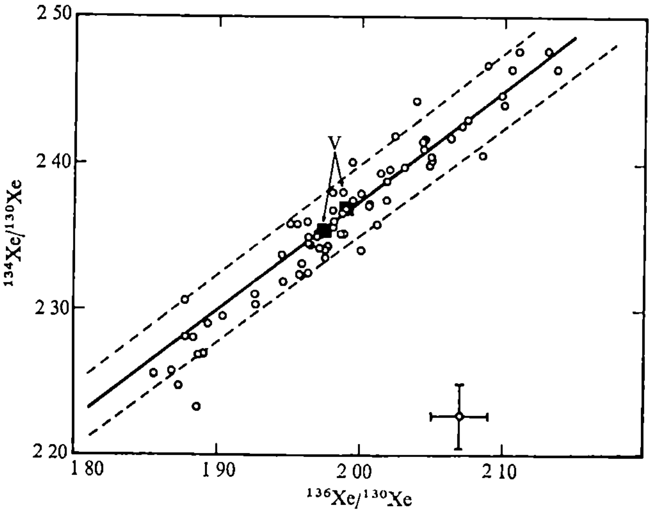

Fig 4 The correlation of ^{134}Xe/^{130}Xe with ^{136}Xe/^{130}Xe in the total xenon of meteorites Data are from a compilation by Mazor *et al*[26] The darkened squares, labelled, V, show the isotopic composition of AVCC and WAVCC xenon Typical error limits of $\pm 1\%$ are shown in the lower right corner

The correlation of excess ^{134}Xe with excess ^{136}Xe for total meteoritic xenon, in the manner observed for xenon released by stepwise heating experiments, suggests that the same mechanism may account for both the isotopic variations in different temperature fractions of a meteorite and the isotopic variations in the total xenon from different meteorites Recently Takaoka[30] reiterated the view that correlations between isotope ratios for ^{128}Xe, ^{130}Xe, ^{131}Xe, ^{132}Xe, ^{134}Xe and ^{136}Xe in the total xenon of different carbonaceous chondrites can be accounted for by the carbonaceous chondrite fission (CCF) hypothesis[6] Takaoka did not, however, consider the isotopic abundances of ^{124}Xe and ^{126}Xe Although the correlation shown in Fig 4 is consistent with both the CCF hypothesis and the component X hypothesis, we assume that the correlation results from variations in the relative amounts of component X for the following reason This same mechanism can also account for isotopic correlations observed in stepwise heating experiments, whereas the CCF hypothesis fails to account for the correlations of excess ^{124}Xe and excess ^{126}Xe with excess ^{136}Xe, as shown in Fig 2

Another mechanism which may contribute to differences in the isotopic composition of atmospheric, solar and AVCC xenon has been noted by Kuroda[31] He suggests that neutron-capture reactions in the interior of the sun during the deuterium-burning stage may have enriched solar xenon in the intermediate mass isotopes, $^{128-132}$Xe Xenon which had been isolated from the sun before the onset of deuterium burning would thus appear to be enriched in the lighter and heavier isotopes, a pattern observed in component X Fractional differences between the abundances of ^{130}Xe in component X and other sources are, however, much larger than those which Kuroda[31] attributes to solar nuclear reactions

From the range of ^{136}Xe/^{130}Xe values shown in Figs 3 and 4 we conclude that for total melt experiments the ^{136}Xe/^{130}Xe ratio may differ from the ^{136}Xe/^{130}Xe ratio in trapped meteoritic xenon by $\approx$0–11% as a result of variations in the relative amounts of component X, whereas stepwise heating experiments partially separate these two components of meteoritic xenon to yield ^{136}Xe/^{130}Xe ratios that are $\approx$0–58% higher than the ^{136}Xe/^{130}Xe ratio in trapped meteoritic xenon AVCC xenon represents the isotopic composition for the average observed mixture of trapped meteoritic xenon and component X

This investigation was supported by grants from NASA and NSF

Gas streaming in 2U0900-40 and Cyg X-1

D. T. Wickramasinghe & M. S. Bessell

Mount Stromlo and Siding Spring Observatory, Research School of Physical Sciences, The Australian National University, Australia

Published photometric data on 2U0900-40 and Cyg X-1 are interpreted as evidence of gas streaming in these systems The location and extent of the gas streams indicate that they originate from the accretion disk and extend to the far side of the primary We suggest that large scale mass loss is occurring from the outer regions of the accretion disk as a result of radiative acceleration by a high luminosity component of soft X rays ($\varepsilon \lesssim 1$ *keV*)*, and offer a possible interpretation of the radio observations of Cyg X-1*

Several X-ray sources have been identified with binary systems the light curves of which show two maxima and two minima per orbital period[1–5] characteristic of 'ellipsoidal' variables The recently reported failure to detect the secondary minimum of Cyg X-1 (refs 6–7) has, however, cast some doubt on the conventional interpretation of the light curves in terms of gravity and limb darkening effects of a tidally distorted star Here we suggest a possible interpretation of both the Cyg X-1 observations, and the recently published photometric data on HD77581 which indicates variability of the light curve following secondary minimum, in terms of a model invoking gas streaming on the 'far side' of the primary as viewed from the X-ray source It is suggested that the variable radio emission observed in Cyg X-1 could originate in an expanding envelope surrounding the binary system

Evidence of gas streaming

Wickramasinghe and Whelan[8] and Hutchings[9] have attempted to analyse the light curve of HD77581 in the framework of a model in which the primary is in near contact with its inner critical Roche lobe but were unable to obtain a detailed fit near secondary minimum Agreement between theory and observations was found to be better if an eccentric orbit is assumed[9] This interpretation, we feel, can now be ruled out on the basis of the detailed observations recently published by Jones and Liller[10] which we present in Fig 1 (Phase $\varphi = 0$ corresponds to X-ray eclipse—also secondary minimum) The solid line corresponds to the theoretical model computed by Wickramasinghe and Whelan[8] assuming a circular orbit The failure to recover full brightness following X-ray eclipse on March 5, 1973, as shown by these observations is strongly suggestive of obscuration of the primary between phases $\varphi = 0$ and $\varphi = 0\ 5$ There is also some evidence for a similar effect on a smaller scale over the same phase in the previous cycle and for even smaller effects at other phases

Any outflow of matter from the primary (defined as the more massive component) through the inner Lagrangian point L_1 is likely to be subsonic and therefore cannot give rise to a gas stream which extends to the far side of the star One of us[11] has recently pointed out the possibility of radiative acceleration of material at the outer edges of the accretion disk by a high luminosity component of soft X rays (of energy $\varepsilon < 1$ keV) In this case, it is possible that some of the radiatively accelerated material could give rise to an optically thick gas stream which falls back on the surface of the primary as illustrated in Fig 2 Alternatively, the material could be accelerated to velocities in excess of the escape velocity resulting in mass loss from the system Either way the flow is expected to be concentrated in the orbital plane with the density being highest near the stellar surface The observed anisotropy of the flow with respect to the line of centres is due to the initial angular momentum of the accelerated material We note that in addition to the diminution in light, the (U–B) and (B–V) colours are expected to become bluer during the equatorial obscuration, since only the hotter polar regions will be visible There is some evidence for this effect in the observational data (Fig 1)

An optically thick region of thickness $\Delta h_{st} \sim 1/10\ R_s$ (normal to the orbital plane) where $R_s \sim 30\ R_\odot$ is the stellar radius, would suffice to explain the observed (0 08 mag) diminution in light at phase $\varphi \approx 0\ 25$ Adopting a value of $5\ R_\odot$ for the radial thickness of the effective obscuring region, we estimate an electron number density $n_e \gtrsim 10^{13}$ cm^{-3} assuming that electron scattering is the dominant opacity source A lower density may be appropriate if the observed extinction occurs over an extended region in the orbital plane

A lower limit to the rate of mass transfer in the gas stream is given by $m_H \Delta h_{st}\ V_g/\sigma_T$ where σ_T, m_H and V_g are the electron scattering cross section, the mass of the hydrogen atom and the stream velocity respectively Assuming that V_g is near the escape velocity the above expression yields $\sim 10^{-7}\ M_\odot$ yr^{-1} The rate of mass loss from the entire disk is thus likely to be at least $10^{-6}\ M_\odot$ yr^{-1} and could be considerably greater

Such a high rate of mass ejection from the accretion disk of the secondary apparently occurs only during some cycles although there is probably continuous outflow at much lower densities This, together with the fact that the observed X-ray luminosity ($\sim 10^{37}$ erg s^{-1}) requires a steady accretion rate of 10^{-8}—$10^{-9}\ M_\odot$ yr^{-1} (ref 12) for a neutron star or black hole secondary, suggests that a local enhancement in the rate of mass transfer from the primary through L_1 could trigger an increase in the rate of radiation-pressure driven mass loss from the outer edges of the disk with little change in the X-ray luminosity In this connection it should be noted that there is considerable observational and theoretical evidence, which supports the hypothesis that mass transfer through L_1 is the dominant mechanism of mass exchange in X-ray binaries with a supergiant component[11]

We note that the theoretical light curve near secondary

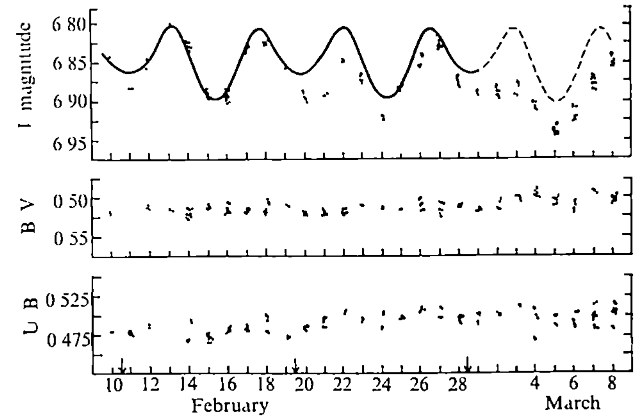

Fig. 1 The V, (B–V) and (U–B) observations of Jones and Liller[10] The arrow corresponds to X-ray eclipse The continuous curve is the zero eccentricity model of Wickramasinghe and Whelan[8] for an orbital inclination $i \sim 90°$ and a mass ratio $q \sim 0\ 09$

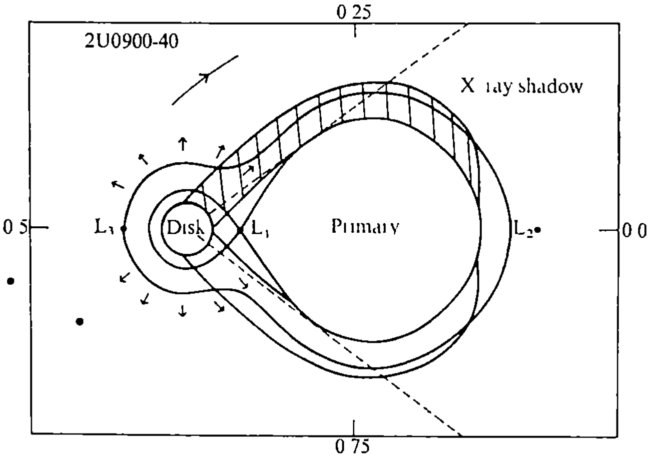

Fig 2 A schematic representation of a possible flow pattern in the orbital plane (neglecting rotation) for a mass ratio $q \sim 0.09$ The Roche equipotentials through the Lagrangian points L_1 and L_3 have been drawn to scale The hatched area represents the probable location of the gas streams causing maximum obscuration

minimum is shallower than the observed light curve even during the first cycle It is plausible that the continuous low density outflow from the disk envisaged earlier could give rise to obscuration mainly near secondary minimum when the material in the region of the X-ray shadow lies between the observer and the primary[8] The possibility of detecting the gas streams spectroscopically should also be greatest at these phases On this interpretation the gas streams nearest the stellar surface are required to fall back on the far side of the primary rather than be accelerated to velocities in excess of the escape velocity

The possibility that radiative acceleration by soft X rays may prevent the development of an appreciable stellar wind from the stellar surface facing the X-ray source has recently been discussed by one of us[11] It is accordingly interesting that the estimated mass flux in the stream indicates that rates of mass loss in excess of normal stellar wind values may be possible from the accretion disk during some cycles The flow patterns in the two cases are however likely to be quite distinct as indicated earlier A wind from the accretion disk would be concentrated largely in the orbital plane and will tend to avoid the region of the X-ray shadow

Walker[6] has observed the light curve of HD226868 over several cycles during the period May to June, 1973 and reports regular primary minima with variable secondary minima The secondary minimum is reported to be completely filled in during some cycles This result has also been confirmed by Martynov[7]

An explanation similar to that offered for HD77581 is possible if it is noted that this system is viewed at a high orbital inclination as is evident from the absence of an X-ray occultation A sufficiently extensive scattering region in the orbital plane at the far side of the primary could thus act as an additional source of light at secondary minimum

We note that the mass ratio $q(=M_2/M_1) \sim 0.6$ of the Cyg X-1–HD226868 system[13] is considerably larger than that of the 2U0900-40–HD77581 system[8] (~ 0.09) where M_1 and M_2 are the masses of the primary and secondary respectively The angular momentum problem is accordingly not as severe, and provided the initial acceleration of disk material is possible (for example by radiation pressure) gas streams may interact at the far side of the primary and form an accretion shock front which could serve as an effective scattering region (Fig 3) The exceptionally large scatter in the light curve[5] indicates that gas streams may contribute to the light at all phases

It is evident that the volume of gas responsible for the filling in of the secondary minimum must be situated sufficiently close to the primary so that it may be eclipsed at the appropriate phases (~ 0.5) A mean distance of $\sim 1.5 R_s$ from the centre of the primary may thus be appropriate (We note that the orbital inclination i must be $<< 90°$ for the present model to be viable suggesting that values of i corresponding to grazing eclipse of the secondary may be required) An order of magnitude estimate of the total number of electrons required to fill in the secondary minimum (of depth ~ 0.06 min) can be obtained from the equation $\sigma_T N_e W/\pi R_s^2 \sim 0.06$ where W is the geometrical dilution factor Setting $W \sim 1/10$, $R_s \sim 10^{12}$ cm we obtain $N_e \sim 10^{48-49}$ Assuming further that the gas occupies a volume 10^{36} cm^3 (1/10 stellar volume)—a plausible value from the eclipse point of view—we obtain an electron number density $n_e \sim 10^{12-13}$ cm^{-3} The scattering region is thus likely to be optically thin ($\tau_{es} \lesssim 1$) and could give rise to a detectable polarisation measure suggesting a possible test of the model Further consequences of the proposed model should be noted

(a) Accretion of matter on to the far side of the primary may result in the heating up of the stellar atmosphere Assuming $M_1 \sim 20\, M_\odot$ and a terminal velocity of the order of the escape velocity, we estimate a 10% increase in effective temperature for accretion rates $\sim 10^{-3}\, M_\odot\ \mathrm{yr}^{-1}$ The observed brightening of the star near secondary minimum could be the result of a general heating effect or a localised hot spot Simultaneous spectroscopic and photometric observations at the appropriate phases would help eliminate this possibility We note that on the scattering model the colours should remain almost unchanged when the secondary minimum is filled in

(b) If we assume that the scattering material is in the region of the shock, the temperature of the gas is likely to be $\sim 10^7$ K We estimate that the infrared contribution due to free–free emission should yield an excess ~ 0.5 mag in (K–M) near secondary minimum if $N_e \sim 10^{49}$ The optical contribution due to free–free emission is 0.1% of the stellar contribution and can be neglected

(c) Cyg X-1 was observed as a weak radio source (2×10^{-28} $W M^{-2}$ Hz^{-1} at 1415 MHz) in April 1971 (ref 14) The source has a nearly flat radio spectrum in the frequency range 1,415–10,630 MHz and was not detected in surveys made before this date[15] We note that free–free emission from an expanding envelope surrounding the binary system could result in an appreciable radio luminosity if the emitting region is optically thin to free–free absorption and is maintained at a high degree of ionisation The former condition requires $n_e^2 L \lesssim 2 \times 10^{25}$ (assuming a temperature $T \sim 10^4$ K characteristic of HII regions) where L is the linear dimension of the emitting region From the observed radio flux at 1,415 MHz we obtain $n_e^2 L^3 \sim 5 \times 10^{58}$ An extended region with $L \sim 5 \times 10^{16}$ cm and $n_e \sim 2 \times 10^4$ cm^{-3} would satisfy the above conditions Whether the gas can remain sufficiently ionised at distances $\sim 10^{16}$ cm from the binary system is difficult to estimate without a detailed model for the outflow.

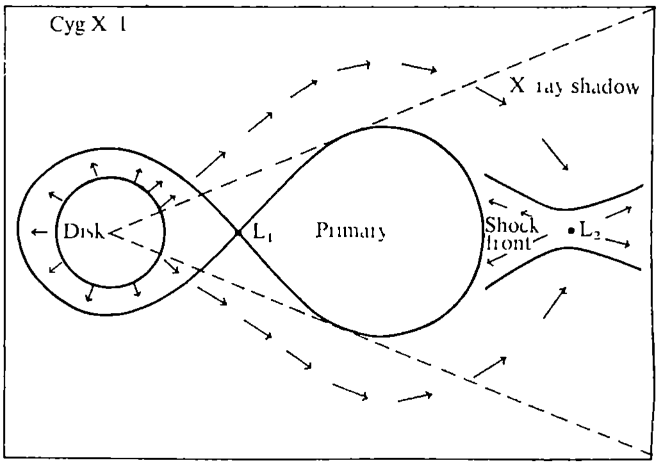

Fig 3 A schematic representation of a possible flow pattern in the orbital plane (neglecting rotation) for a mass ratio $q \sim 0.6$ The location of the accretion shock front is also indicated

We note, however, that a Stromgren sphere surrounding such a star would have a dimension ~ 10^{17} cm (ref 16) if the particle density is as high as ~ 2×10^4 cm^{-3} indicating that our suggestion is plausible

Since the details of the outflow from the accretion disk are not known it is not clear at present whether velocities in excess of the escape velocity can be achieved as a result of radiative acceleration by soft X rays Preliminary estimates indicate that continued radiative acceleration is more likely to be achieved by the stellar ultraviolet radiation Mass loss from the system may thus occur in the form of an intense 'stellar wind', the material of which originates from the accretion disk Until the details of the model are worked out, our suggested interpretation of the Cyg X-1 observations must be considered as tentative

Our conclusions may be summarised as follows

(1) The observed variations in the shape of the light curve of HD77581 following X-ray minimum can be interpreted in terms of a model invoking gas streaming The location and extent of the gas streams indicate that they originate from the accretion disk, possibly as a result of radiative acceleration The variability of the gas streams is attributed to local changes in the rate of mass transfer through the inner Lagrangian point, which in turn effects the rate of mass loss from the disk

(2) The Cyg X-1 observations can be interpreted in terms of a scattering region of volume 10^{36} cm^3 and electron density $n_e \sim 10^{12-13}$ cm^{-3} situated at a distance of ~ 1 5 stellar radii from the primary The model predicts a detectable polarisation measure and an infrared excess of ~ 0 5 mag in K–M near X-ray eclipse The observed variable radio emission could originate as a result of free–free emission from the optically thin regions of an expanding envelope surrounding the binary system

(3) In view of the possible importance of gas streaming in 2U0900-40 and Cyg X-1, the determination of orbital eccentricities from the light curves must be viewed with caution The interpretation of the radial velocity observations of these systems could also be complicated by gas streaming effects at certain phases

We thank Dr A R Hyland for discussions and the referee for his comments

DNA polymerase activity from two temperature-sensitive mutants of Rous sarcoma virus is thermolabile

Inder M. Verma,[†] William S. Mason,[*][‡] Stanley D. Drost & David Baltimore

Temperature sensitivity of growth and transformation by certain early Rous sarcoma virus mutants correlates with thermolability of their virion-associated DNA polymerase The enzyme is therefore encoded by viral RNA and is required for provirus synthesis

Two temperature sensitive mutants of Rous sarcoma virus (RSV) have been isolated which have defects very early in their growth cycle (ref 1 and W S M, R R Friis, M Linial and P K Vogt, in preparation) They are called *ts*335 and *ts*337 Their temperature sensitive function is necessary for the initiation but not the maintenance of both viral replication and cell transformation (ref 2 and in preparation) The DNA polymerase activity in the mutant virions appears to be temperature sensitive when assayed with either endogenous or exogenous templates (ref 2 and in preparation) (According to the system for virus nomenclature proposed by Vogt, Weiss and Hanafusa[3] these viruses are designated as *ts*LA335PR-C and *ts*LA337PR-C)

We have purified the DNA polymerase from both *ts*335 and *ts*337 and compared the activities of the purified enzymes with those of the DNA polymerase of wild type RSV The three known activities of the avian RNA tumour virus DNA polymerase have been studied RNA-directed DNA synthesis, DNA-directed DNA synthesis, and ribonuclease H (which selectively degrades the RNA portion of a DNA-RN hybrid[4])

Thermolabile enzymes

DNA polymerase activity of detergent-treated *ts*335 and wild type RSV virions at 34°, 37° and 40 5° C was measured both in the endogenous reaction and after addition of an exogenous template primer The endogenous activity of *ts*335 was slightly lower at 40 5° C than at 34° C, while the activity of the RSV wild type increased two-fold through this temperature range (Table 1) With poly(C) oligo(dG) as an added template·primer[5], *ts*335 DNA polymerase incorporated about one-third

Table 1 DNA polymerase activity associated with purified virions of *ts*335 and RSV wild type

Temperature (°C)	Endogenous activity (pmol ^{3}H-dAMP incorporated) *ts*335	RSV(WT)	Ratio of RSV(WT):*ts*335	Exogenous activity with poly(C) oligo(dG) (pmol ^{3}H-dGMP incorporated) *ts*335	RSV(WT)	RSV(WT):*ts*335
34	40	28	0.7	239	315	1.32
37	35	41	1.17	203	375	1.85
40.5	33	61	1.84	68	406	5.97

* The wild type sarcoma virus was the Prague strain (RSV(WT), *ts*335 was isolated as described[1]. Both viruses belong to subgroup C. The virus stocks were grown at 35° C and purified as before[2]. Protein concentrations were determined using the procedure of Lowry *et al.*[23] with bovine serum albumin as a calibration standard. All oligomers used as primers were 12 to 18 nucleotides long.

For the endogenous reaction, assays of heat lability were performed by incubating the purified virions in 0.1 ml of reaction mixture containing 50 mM Tris-HCl, *p*H 8.3, 5 mM dithiothreitol, 6 mM magnesium acetate, 60 mM NaCl, 60 nmol each dTTP, dCTP, and dGTP, 20 nmol ^{3}H-dATP (specific activity 100 c.p.m. pmol^{-1}), Nonidet P-40 to a final concentration of 0.2%, and 12 µg of viral protein. The reaction mixtures were incubated separately at 34° C, 37° C, or 40.5° C for 90 min and radioactivity in acid insoluble material was detected as described before[24]. To assay exogenous activity, purified virions containing 2.4 µg of protein in 0.05 ml of reaction mixture I (100 mM Tris-HCl, *p*H 8.3, 10 mM dithiothreitol, 12 mM Mg acetate, 60 mM NaCl, and 0.2% Nonidet P-40) were incubated at 34° C, 37° C, or 40.5° C for 10 min. After preincubation, to each reaction mixture was added 0.05 ml of reaction mixture II (20 nmol ^{3}H-dGTP, (100 c.p.m. pmol^{-1}), 2.0 µg poly(C) and 0.5 µg oligo(dG)). The reaction mixture was further incubated for 15 min at 34° C, 37° C or 40.5° C and acid-precipitable radioactivity monitored as described before[24].

the amount of ^{3}H-dGMP at 40.5° C as at 34° C, while incorporation by wild type RSV DNA polymerase was increased at 40.5° C (Table 1). Thus, in disrupted virions, the *ts*335 DNA polymerase was more sensitive to thermal inactivation than the wild type RSV DNA polymerase, in agreement with previous data[2].

DNA polymerase was purified from wild type RSV and from the two mutants by standard procedures[6]. Although the enzymes from the mutants were inactivated more extensively than the wild type enzyme during purification and subsequent storage at −70° C in 20% glycerol, the three enzymes behaved indistinguishably during ion-exchange chromatography on DEAE-Sephadex and phosphocellulose.

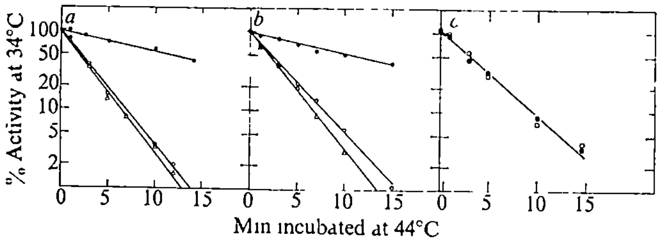

Fig. 1 Thermal inactivation of purified DNA polymerases from mutant and wild type virions using ribohomopolymers as templates. Purified virions of *ts*335, *ts*337 and wild type RSV were obtained as described before[2]. About 4 to 6 mg of viral protein was used for enzyme purification. Virions were lysed and the DNA polymerase purified by chromatography on DEAE-Sephadex and then on phosphocellulose columns as before[6]. DNA polymerase from the mutants *ts*335 and *ts*337 (clone β)[2] and wild type RSV (clone B)[2] eluted at a concentration of 0.06 to 0.08 M KCl from DEAE-Sephadex and 0.24 to 0.30 M KCl from phosphocellulose. A recovery of 40–50% of DNA polymerase was achieved by carrying out the procedures as rapidly as possible. Heat lability was assayed by preincubating the DNA polymerase in reaction mixture I, which contained 100 mM Tris-HCl, *p*H 8.3, 20 mM dithiothreitol, 12 mM magnesium acetate, 120 mM NaCl and 0.05–1.0 U of purified enzyme per 0.05 ml (A unit of enzyme activity is defined as the amount of enzyme required to incorporate 100 pmol of ^{3}H-dGMP at 37° C in 15 min[6].) The reaction mixture was incubated at 44° C. At various intervals aliquots of 0.05 ml were withdrawn and added to 0.05 ml of reaction mixture II which contained template, primer and substrates. This was kept on ice for 10–15 min, then incubated at 34° C for 15 min. Acid-precipitable radioactivity was measured as described[24]. The rate of the enzyme reaction at 34° C was linear for at least 15 min. *a*, Poly (C) (1.0 µg) and oligo (dG) (0.5 µg) were template primer with 20 nmol ^{3}H-dGTP (100 c.p.m. pmol^{-1}) as substrate. ●, RSV wild type; ○, *ts*335; △, *ts*337. *b*, Poly(A) (1.0 µg) and oligo(dT) (0.5 µg) were template primer with 20 nmol ^{3}H-dTTP as substrate. Symbols are as in (*a*). *c*, ●, rabbit reticulocyte 10S RNA (30 nmol nucleotide) and oligo(dT) (140 pmol nucleotide) were template primer with 20 nmol ^{3}H-dGTP (100 c.p.m. pmol^{-1}) and 60 nmol each of dATP, dCTP and dTTP as substrate and DNA polymerase from *ts*337. Reaction mixture II was incubated at 34° C for 60 min. ○, poly(C) oligo(dG) were template primer as in (*a*).

Electrophoresis on SDS-containing polyacrylamide gels followed by staining with Coomassie blue[7], showed that the purified DNA polymerases from *ts*335, *ts*337 and wild type RSV had two polypeptide bands of average molecular weight 88,000 and 56,000. The subunits were in equimolar ratio. In some samples there occasionally appeared a faint band at about 64,000 which we assume to be a contaminant. The purified DNA polymerase from avian myeloblastosis virus (AMV) was not distinguishable from the RSV enzymes. These values for the molecular weights of the polypeptides of the DNA polymerase are somewhat lower than those reported by others[8-10].

The heat-inactivation kinetics of the ability of the purified enzymes to copy ribohomopolymers were assayed using poly(C) oligo(dG) and poly(A) oligo(dT) as template primers. Enzymes were preincubated at 44° C and assayed at 34° C. The enzyme purified from mutant virions was inactivated about three times more rapidly at 44° C than that from RSV wild type virions (Fig. 1*a* and *b*). There was a small reproducible difference between the rates of inactivation of the two mutants, with the *ts*337 enzyme being more heat sensitive.

To test the ability of the enzymes to transcribe RNA heteropolymers, we used 10S RNA from rabbit reticulocytes (globin mRNA) as a template with an oligomer of dT as primer[4]. Figure 1*c* shows that the rate of heat inactivation of the ability of the *ts*337 enzyme to transcribe 10S RNA oligo(dT) was identical to that measured with poly(C) oligo(dG).

When heat-inactivation kinetics were assayed using a deoxyribohomopolymer, poly(dC) primed with oligo(dG), again enzymes from the mutants were inactivated more rapidly than the wild type enzyme. The enzymes from the mutants were inactivated slightly more slowly with this DNA template than with the homologous RNA template of poly(C), while the wild type enzyme was inactivated at the same rate with both templates. The *ts*335 enzyme was again slightly less thermosensitive than the *ts*337 enzyme. Using nuclease-treated calf thymus DNA[11], data indistinguishable from that in Fig. 2 were obtained with enzymes from both mutants and RSV wild type.

We investigated whether reduced binding of the enzyme from the mutants to the template might be partly responsible for their thermolability. Figure 3 shows that if template · primer was added to the reaction mixture during preincubation of DNA polymerases at 44° C, the wild type enzyme was protected against heat inactivation, whereas that of *ts*335 was inactivated at the same rate as in the absence of template. These inactivation conditions, which show such a large difference between wild type and mutant, may be more relevant to the *in vivo* situation than inactivation in the absence of template.

The purified DNA polymerases from *ts*335, *ts*337 and wild type RSV all exhibit, in addition to DNA polymerase activity, a nuclease activity which selectively removes the RNA moiety from a DNA–RNA hybrid (ribonuclease H activity). Figure 4*a* shows the activity of polymerase-associated ribonuclease H from *ts*335, *ts*337 and wild type RSV after incubation at 44° C for various times. The activity from the mutant was more sensitive to temperature than that from the wild type. However, the ribonuclease H activity was less sensitive to inactivation at 44° C than was the DNA polymerase activity[12]. At 47° C the ribonuclease H activity of *ts*337 DNA polymerase was much more thermolabile than the wild type enzyme (Fig. 4*b*).

The half lives of the synthetic and degradative activities of purified DNA polymerase from the mutants and the wild type RSV are collected in Table 2. The enzymes from the mutants were four to ten times more heat labile than those from the wild type virus.

Revertants and recombinants

Mason *et al.* (in preparation) isolated revertants of both *ts*335 and *ts*337 which are no longer temperature sensitive for the initiation of infection at 41° C. To see if the phenotypic reversion was paralleled by a reversion of DNA polymerase to wild type behaviour, the heat inactivation kinetics of the DNA polymerase activity in virions of revertants of *ts*335 and *ts*337 were compared with that of mutant *ts*337 utilising poly(C) oligo(dG) and poly(dC) oligo(dG) as template primers. The virion-associated DNA polymerase activity of the revertants was three or four times more heat stable than that of the mutants (Fig. 5*a* and *b*). Similarly, the ribonuclease H activity of the DNA polymerase of the revertants was ten times more resistant to thermal inactivation than ribonuclease H activity from the mutants (Fig. 5*c*). Therefore both the biological and biochemical parameters vary together during selection for reversion of the temperature sensitive lesion.

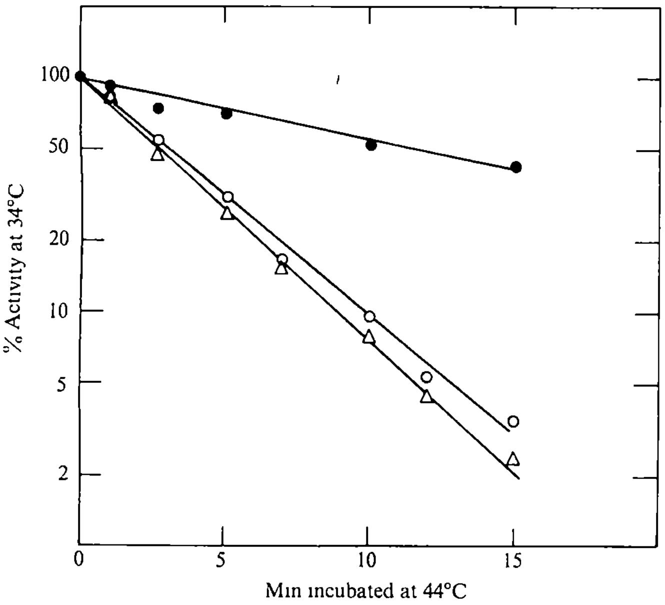

Fig. 2 Thermal inactivation of the DNA polymerase activity of mutant and wild type enzymes with poly(dC) oligo(dG) as template. The same reaction conditions were used as described in the legend to Fig. 1*a*, except that 1.0 μg of poly(dC) was substituted for poly(C). ●, RSV wild type, ○, *ts*335, △, *ts*337.

Because the mutants were isolated from a transforming virus of host range subgroup C Prague RSV, recombinants could be selected from mixed infections with the group B non-transforming leukosis virus, RAV-6[13,14]. Recombinants were selected as transforming viruses of group B. The temperature-sensitive lesion was an unselected marker because permissive temperature was used throughout the selection. Recombinant clones were then screened for temperature sensitivity of growth and transformation (W. S. M., R. R. Friis, M. Linial and P. K. Vogt, in preparation).

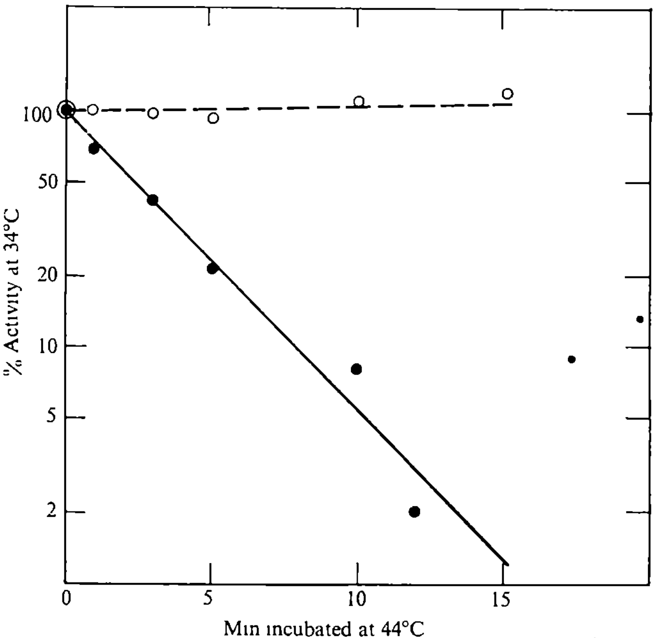

Fig. 3 Effect of template primer on the rate of heat inactivation of mutant and wild type RSV DNA polymerase activity. The reaction was as described for Fig. 1*a*, except that template primer was included in reaction mixture I. ○, RSV wild type, ●, *ts*335.

Heat inactivation kinetics of the DNA polymerase activity in the virions of the wild type and temperature sensitive recombinants were assayed (Fig. 6). Both synthetic and degradative activities of the DNA polymerases of the wild type viruses were more thermostabile than those of enzymes of the temperature sensitive recombinants.

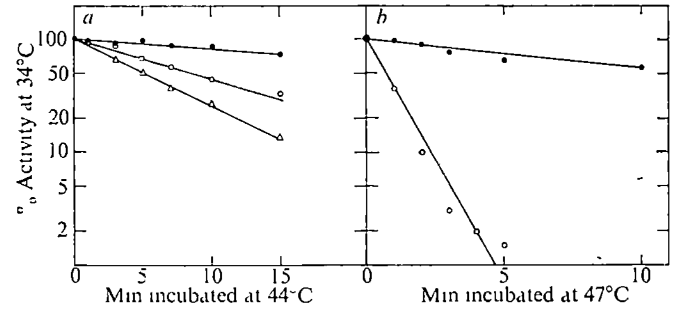

Fig. 4 Thermal inactivation of ribonuclease H activity of mutant and wild type RSV DNA polymerase. Ribonuclease H was assayed by using ^{3}H-poly(A) poly(dT) as substrate and monitoring the degradation of ^{3}H-poly(A) to acid-soluble material. Heat inactivation was carried out as for Fig. 1 by preincubation at either 44° C or 47° C followed by incubation at 34° C. Reaction mixture I was as for Fig. 1*a*, except that 40 mM Mg acetate and 60 mM NaCl were used. Reaction mixture II contained 10 pmol of ^{3}H-poly(A) (1,000 c.p.m. pmol^{-1}) and 2.8 pmol of poly(dT). The reaction at 34° C was carried out for 60 min under an atmosphere of nitrogen. The acid-soluble radioactivity was determined by first adding 10 μl of 10 mg ml^{-1} bovine serum albumin and 30 μl of 50% trichloroacetic acid to the reaction mixture at the termination of incubation. After 15 min at 4° C, the samples were centrifuged in a bench-top centrifuge at full speed for 3 min and 100 μl aliquots were withdrawn from the supernatant and counted directly in 5.0 ml of dioxane-based scintillation fluid. The degradation of poly(A) by the unincubated enzyme is represented as 100%. All other values are normalised to the value of the unincubated sample. *a*, ●, RSV wild type, ○, *ts*335, △, *ts*337. *b*, ●, RSV wild type, ○, *ts*337.

Table 2 Average times for inactivation of half of the activities of the purified DNA polymerase from mutant and wild type RSV

Source	DNA polymerase activity at 44° poly(C) oligo(dG)	 poly(dC) oligo(dG)	Ribonuclease H activity at 44° C	 47° C
RSV wild type	11 5	11 5	30	13
*ts*335	2	3	7 4	—
*ts*337	1 8	2 8	5	1 5

Values are expressed in min as $t_{1/2}$, which is the time required for inactivation of 50% the relevant activity as determined in Figs 1, 2 and 4

Implications of thermolability

RNA tumour viruses contain a DNA polymerase which can utilise polyribonucleotides as templates to synthesise a faithful complementary DNA transcript[4] This enzyme has been attributed a central role in the provirus hypothesis[15] In the scheme of events postulated in the provirus hypothesis, such an enzyme needs to be operational just after infection for the synthesis of DNA complementary to viral RNA However, it has not previously been possible to determine unambiguously if the virion DNA polymerase is responsible for provirus synthesis and if the enzyme is coded by the viral genome or is cellular in origin Virus-specificity of the enzyme has been suggested because it appears only after infection of the cell[16,17] The finding of noninfectious virions lacking DNA polymerase has been interpreted as evidence for an obligatory role for the enzyme[18-21]

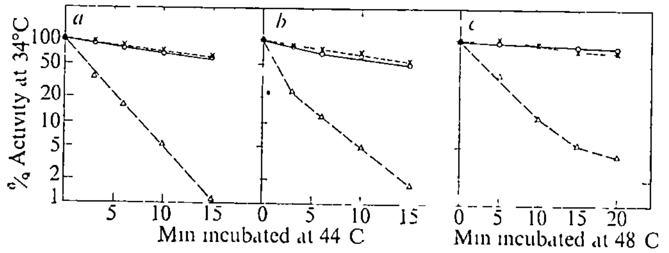

Fig 5 Thermal inactivation of polymerase and nuclease activity associated with purified virions of revertants of *ts*335 and *ts*337 Spontaneous revertants of *ts*335 and *ts*337 were selected by growth of the temperature sensitive viruses at the non-permissive temperature (41° C) Cloned revertant stocks were then isolated at the permissive temperature (35° C) For the experiments reported in this figure, 7 0 μg of viron protein from the following stocks was used *ts*335 revertant clone A-3, *ts*337 revertant clone γ-2 and *ts*337 clone γ (W S M , R R Friis, M Linial and P K Vogt, in preparation) *a*, Inactivation of polymerase activity measured with poly(C) oligo(dG) as in Table 1 *b*, Inactivation of polymerase activity measured with poly (dC) oligo(dG) as in Table 1 *c*, Inactivation of ribonuclease H activity measured as in Fig 4 Preincubation was at 48° C ×, *ts*335 revertant, ○, *ts*337 revertant, △, *ts*337

The study reported here demonstrates covariation of thermolability of the virion DNA polymerase with temperature sensitivity of infection and transformation by the virions Two early temperature sensitive mutants of RSV were found to have DNA polymerase more thermolabile than that of the wild type virus, while revertants of the mutants (W S M , R R Friis, M Linial and P K Vogt, in preparation) as well as a class of wild type recombinants[2] had DNA polymerase with wild type properties This indicates that RSV RNA encodes the information for at least part of the DNA polymerase molecule and the enzyme must be necessary to initiate infection or transformation by RSV Bishop *et al* [27] reported that less viral DNA is produced by *ts*335 and *ts*337 at nonpermissive temperature than is produced by the wild type virus, which implies that the virus-encoded DNA polymerase is responsible for the synthesis of DNA after infection by RNA tumour viruses

All three activities of the purified DNA polymerase from avian tumour viruses show increased thermolability in the DNA polymerase of the mutant viruses, and therefore seem to reside in the same polypeptide chain Grandgenett *et al* [8] have shown that the isolated, lower molecular weight subunit of AMV DNA polymerase manifests both the synthetic and the degradative activities of the whole enzyme We have confirmed this for RSV and have isolated the small subunit of the DNA polymerase from *ts*337 and wild type virus Both synthetic and degradative activities of the isolated small subunit of *ts*337 showed heat-inactivation kinetics indistinguishable from those of the complete *ts*337 DNA polymerase (I M V , A Panet and W S M , in preparation) The lower molecular weight subunit must therefore be encoded by viral RNA, the origin of the other subunit is under investigation

We thank Dr John Wyke for isolating *ts*335, Dr G F Temple for globin mRNA, Drs Hung Fan and William Haseltine for stimulating discussions, Nora Meuth, Tad Nitasaka and Philip Harris for technical assistance and Dr Peter Vogt for generous support This study was supported by contracts from the Virus-Cancer Program of the National Cancer Institute to D B and to Peter Vogt and by grants from the US Public

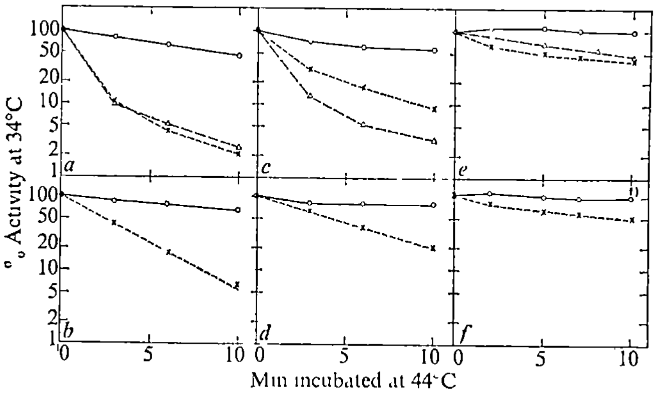

Fig 6 Thermal inactivation of DNA polymerase and ribonuclease H activity of various stocks of recombinants Recombinants between temperature sensitive RSV stocks of subgroup C and avian leukosis virus RAV-6 of subgroup B, were isolated as described (W S M , R R Friis, M Linial and P K Vogt, in preparation)[3] The recombinant sarcoma viruses had the subgroup B host range characteristic of RAV-6 and were of either wild type or temperature sensitive genotype We have used the following nomenclature *ts*337 × RAV(WT) or *ts*335 × RAV(WT) the mutant virus was co-cultivated with RAV-6 and the resultant viruses after appropriate screening could transform and replicate at non-permissive temperature (41° C) The following clones were used to prepare virus stocks *ts*337 × RAV(WT), clone 21, *ts*335 × RAV(WT), clone 17 (in preparation as above) *ts*337 × RAV(Ts) or *ts*335 × RAV(Ts) the mutant virus was cocultivated with RAV-6 and the resultant viruses after appropriate screening could not transform or replicate at nonpermissive temperature (41° C) The following clones were used to make virus stocks *ts*337 × RAV(Ts), clone 7, *ts*335 × RAV(Ts), clone 14 (in preparation as above) *a*, Poly(C) oligo(dG) was template primer ○ *ts*337 × RAV(WT), ×, *ts*337 × RAV(Ts), △, *ts*337 *b*, Poly(C) oligo (dG) was template primer 0, *ts*335 × RAV (WT), X, *ts*335 × RAV (Ts) *c* and *d*, Poly (dC) oligo (dG) was template primer Symbols as in *a* and *b*, respectively *e* and *f*, Ribonuclease H assays Symbols as in *a* and *b*, respectively

Membrane structure changes in rod outer segments associated with rhodopsin bleaching

P. A. Liebman, W. S. Jagger*, M. W. Kaplan & F. G. Bargoot
Department of Anatomy and Johnson Foundation, University of Pennsylvania, Philadelphia, Pennsylvania 19174

Static and time resolved birefringence analysis is used to quantitate a fast membrane structure change driven by the formation of metarhodopsin II in intact frog retina. This change can be accounted for by the disorientation of only one phospholipid molecule per rhodopsin bleached.

SCHMIDT'S discovery and analysis of the radially positive birefringence of myelin sheath and of the positive uniaxial birefringence of retinal rod outer segments (ROS) gave early evidence of a two-dimensional liquid crystalline structure for biological membranes[1]. More recently, time-resolved birefringence measurements have been made in attempts to detect structural alterations, such as lipid reorientation, suspected to accompany action potentials in excitable membranes. Very small transient changes from the resting birefringence associated with action potentials of nerve, electroplax and muscle have been detected, usually by summing many responses in a signal averager[2–6]. Where sufficiently extensive analysis of these responses has been possible, however, the birefringence transients have been found to be secondary to the excitation process rather than part of its mechanism[7]. This does not mean that there is no primary alteration of membrane anisotropy, but rather that the surface density of sites at which such changes occur in these tissues may be too small to be detected, or may be small compared with the background of less interesting changes.

It is not surprising that little effort has been made to look for small changes in the birefringence of rods coincident with excitation, since the light used to observe the birefringence may at the same time alter the system by bleaching its pigment. Nevertheless, our experience using infrared image converters and sensitive photomultipliers to deal with dark adapted ROS[8], suggested that a birefringence analysis of this material might be feasible and would be especially worthwhile for the following reasons.

Individual frog ROS contain 2.5 mM rhodopsin in an 1,800 μm^3 volume[9]. Thus 3×10^9 equipotent trigger molecules[10] are embedded in the 4,000 closely stacked lamellar membranes (2,000 disks), each of 28 μm^2 area to yield a surface density of 25,000 rhodopsins per μm^2. This, for example, exceeds by 1,000 times the density of sodium channels in nerve[11]. The 60-μm long ROS themselves lie parallel to one another in a dense array without intervening inactive material (cytoplasm, mitochondria, Schwann sheath, myelin) so predominant in nerve. In sum, the features of very high active membrane density and good alignment of extensive material of high purity provide a most appropriate subject for birefringence analysis.

ROS birefringence transient

Using an infrared dissecting microscope, dark adapted retinae from *Rana pipiens* were isolated in frog Ringer solution. For static birefringence studies, outer segments were dislodged on a microscope slide by gently tapping a piece of retina against the slide. A drop of Ringer or 12% gelatin-Ringer solution was added, the preparation closed with a cover-slip and the edges blotted dry and sealed with paraffin wax as before[12]. For kinetic studies, the retina was cut into a dozen or more strips, each of which curled spontaneously to form a tube with the ROS outermost. Each was transferred to a microscope slide and surrounded by a paper spacer to prevent squashing when the cover-slip and wax were added. These strips form so-called 'edge-fold'

---

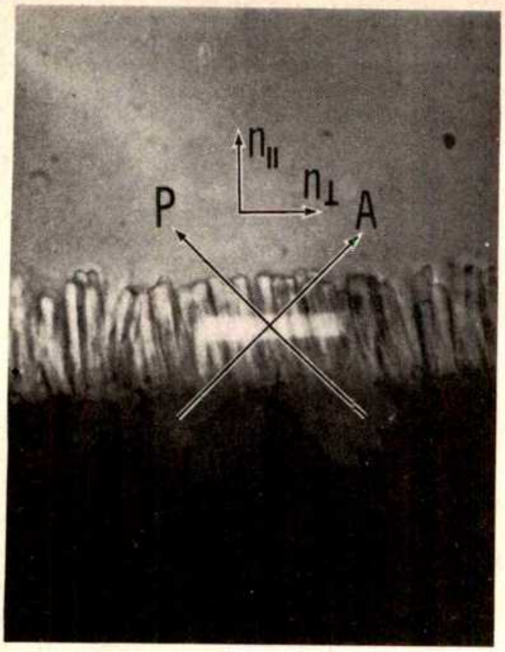

Fig. 1 Edge-folded retina showing aligned rows of rod outer segments with measuring beam superimposed. For birefringence measurement, light initially polarised at a 45° angle (P) with respect to the ROS axis traverses the cell. Since $n_{\parallel} > n_{\perp}$, the phase of the electric field component parallel to the rod axis is retarded with respect to the component perpendicular to it. An analyser (A) transmits only the minor axis component of the resultant elliptically polarised light emerging from the ROS. The birefringence, $\Delta n = n - {}_{\parallel}n_{\perp}$, is defined as axially positive when $n_{\parallel} > n_{\perp}$.

preparations in which aligned rows of ROS project from the edge of the retina[13]. Birefringence observations were made using a low numerical aperture polarising microscope equipped for infrared viewing and with an inverted objective lens as a condenser. A low intensity measuring beam of monochromatic light (30 μm × 300 μm at the specimen plane) was imaged on the ROS layer (Fig. 1). A 1-ms xenon bleaching flash beam was demagnified to the same dimensions as the measuring beam and superimposed on it using a beam splitter. The flash was made blue-green by a Wratten 47B filter together with a series of infrared absorbing glass filters. Its intensity was sufficient to bleach 50–60% of the pigment with each flash, a saturating bleach[14,15]. The flash was blocked from the photomultiplier by a red-transmitting cutoff filter. Birefringence transients initiated by the flash were detected as a change in measuring beam intensity through a system of crossed polariser and analyser with the specimen in between. The axis of the ROS was at an angle of 45° with respect to the polariser axis (Fig. 1). Transmitted intensity was recorded using a storage oscilloscope directly coupled to the amplified output of the detecting photomultiplier (S-20 cathode).

To avoid problems of interpretation due to visual pigment absorption changes on bleaching, flash-induced birefringence changes were initially sought at wavelengths longer than 650 nm, outside the absorption band of rhodopsin. Exposure to a saturating flash initiated a rapid 6–8% loss of light transmission, corresponding to a 3–4% decrease in the net birefringence (Fig. 2). Flashes of reduced intensity caused proportionally smaller changes. The transmission loss had the action spectrum of rhodopsin. A 1/20λ retardation plate inserted between polariser and specimen served both to calibrate the instrument and to prove that the signal measured was a change in birefringence. When this plate was positioned so as to add to the specimen birefringence, the flash-induced signal was a reduction of transmitted light intensity. When the plate was rotated to produce a total static retardation of the same magnitude but of opposite sign, the signal was inverted. This shows that the flash-induced signal was not due to absorption, optical rotation or light scattering changes in the specimen, but that it was due to a change in birefringence.

Wavelength dependence

In experiments using measuring lights of different wavelength, the birefringence transient (BRT) was found to be achromatic at wavelengths between 700 nm and 650 nm, to vanish between 650 nm and 600 nm and to be reversed in sign (birefringence increase) from 600 nm to 550 nm, increasing in magnitude with decreasing wavelength. This peculiar wavelength-dependent behaviour of the BRT was understood through measurement of the static wavelength dependence of the birefringence of single dark adapted ROS. Our dual beam low-light-level wavelength scanning microspectrophotometer[8] was altered by insertion of crossed polarisers and a 1/20λ retardation plate to allow birefringence recording. The logarithm of the transmission ratio between a region containing the retardation plate alone and that containing a single ROS plus retardation plate was measured using microbeams of cellular dimensions without detectable visual pigment bleaching. Figure 3*a* shows the results of such a recording with the slow axis of the retardation plate parallel to the ROS long axis (the birefringence slow axis). Reversal of the retardation plate orientation leads to mirror inversion of the recorded spectrum, indicating that the entire spectrum is due to birefringence. The effect of fractional bleaches of the visual pigment is immediately to reduce the peak-to-peak amplitude of the spectral excursions. A slow achromatic increase in birefringence also occurs subsequent to bleaching with a half-time of about 20 min at 20° C. The retardation spectrum in Fig. 3*b* was computed from the recorded transmission spectrum using the formulae derived by Szivessy[16]. The resulting curve can be understood in the following way. When matter interacts

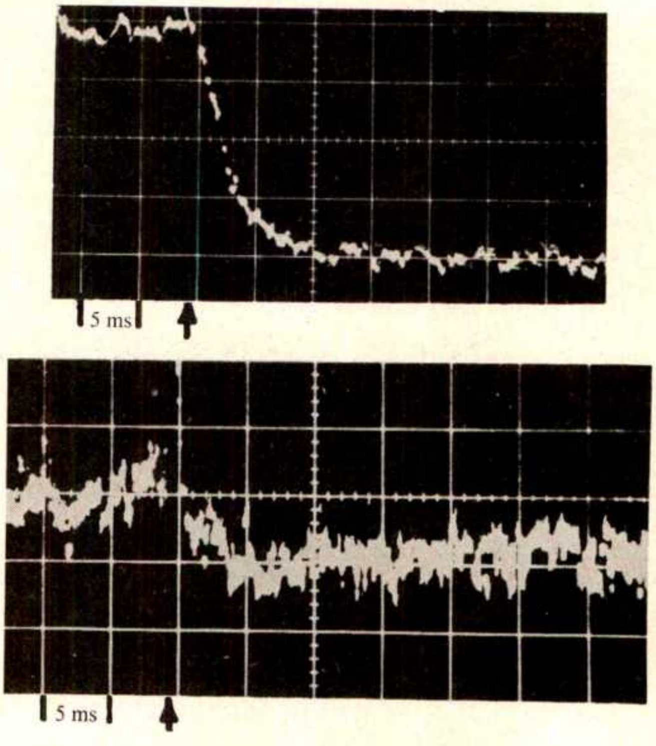

Fig. 2 Comparison of metarhodopsin II (MII) formation and the BRT. The upper oscilloscope trace shows the *in situ* loss of light transmission at λ=380 nm due to a flash induced (at arrow) increase in MII concentration. The temperature was 21.5° C. The lower trace shows the BRT at λ=680 nm under the same conditions. The temperature was 21.8° C.

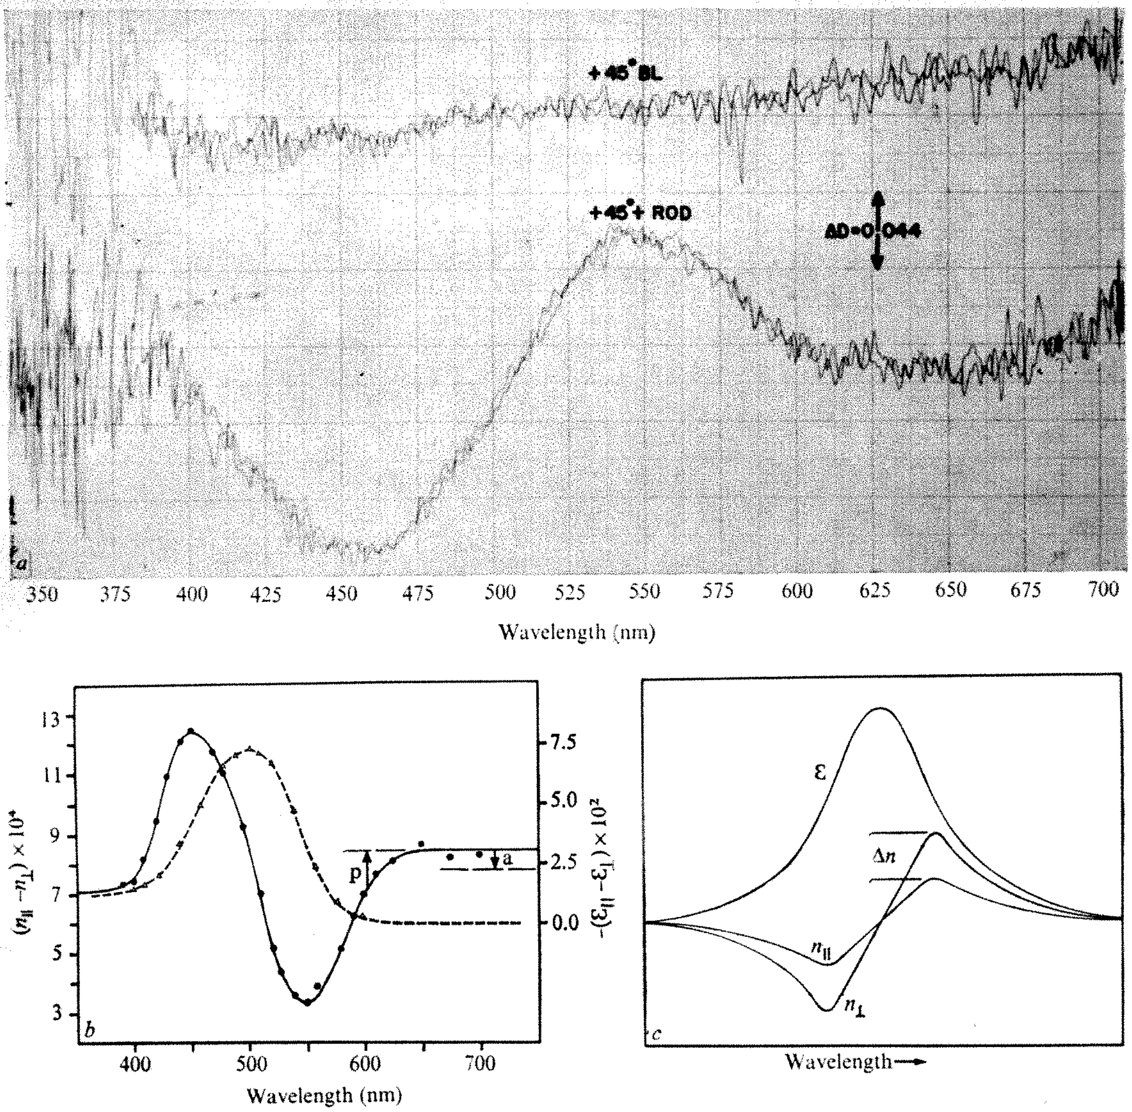

Fig. 3 *a*, Wavelength dependence of transmitted light intensity due to dark adapted ROS static birefringence plus a λ/20 plate aligned with its slow axis along the ROS axis, 45° from the polariser axis (+45° + ROD). Superposition of two successive scans shows that no bleaching occurs during the measurement. Baseline taken in the absence of the ROS (+45° BL). Intensity increases downward. ΔD is the equivalent optical density change. *b*, Birefringence spectrum (●) computed from data of (*a*). Arrow a indicates the flash-induced achromatic birefringence loss. Arrow p indicates the wavelength-dependent birefringence change due to loss of visual pigment related anomalous dispersion differences. The direction and magnitude of the BRT depends on the relative magnitudes of a and p at a given wavelength. Dichroism spectrum (△) showing a higher absorption coefficient for the perpendicular (to the rod axis) component than for the parallel component, the maximum difference occurring at the absorption peak of rhodopsin. *c*, Schematic diagram showing that the anomalous dispersion of the refractive index in the region of the rhodopsin absorption peak is more pronounced for the perpendicular direction, $n_{\perp}$, than for the parallel direction, $n_{\parallel}$, due to dichroism of the visual pigment. For wavelengths longer than the absorption peak, the anomalous dispersion-dependent birefringence component is negative ($n_{\parallel}-n_{\perp}<0$). Loss of this negative component on bleaching contributes an increase to the net birefringence.

with light, in the region of an absorption band, there can be both absorption of photons and a phase change (retardation) of the transmitted wave. These properties are expressed as the imaginary and the real part of the complex index of refraction respectively. The two components of the complex index are mathematically related by the Kramers-Kronig or other dispersion relationships[17,18]. In spectral regions distant from the absorption peak, the real part of the refractive index, *n*, decreases with increasing wavelenght ($dn/d\lambda<0$). However, in the region of the absorption peak, *n* increases with increasing wavelength ($dn/d\lambda>0$), producing an anomalous dispersion effect. Intact ROS are dichroic because of the net orientation of rhodopsin chromophores in the membrane. Absorption of light polarised perpendicular to the rod axis (in the plane of the lamellar membranes) is four to five times more efficient than of light polarised parallel to the rod axis[12]. Similarly, this means that the anomalous dispersion associated with rhodopsin absorption will be more pronounced for the perpendicular component of the refractive index, $n_{\perp}$, than for the parallel component, $n_{\parallel}$, as shown schematically in Fig. 3*c*. Our birefringence spectrum in the region of the absorption peak measures the difference, $\Delta n=n_{\parallel}-n_{\perp}$, between the dispersion curves for the two polarisations. Note that this anomalous dispersion component of the overall birefringence is negative with respect to the rod axis for wavelengths longer than the absorption peak.

Possible sources of BRT

Could the disappearance of the visual pigment anomalous dispersion effect as a result of bleaching then explain the observed long-wavelength BRT. Evidently not, for this loss of negative birefringence would cause an increase in the (positive) net birefringence whereas a decrease is actually observed. If the long-wavelength BRT, however, is due to the concurrent loss of a wavelength-independent positive contribution to the net birefringence, such as would

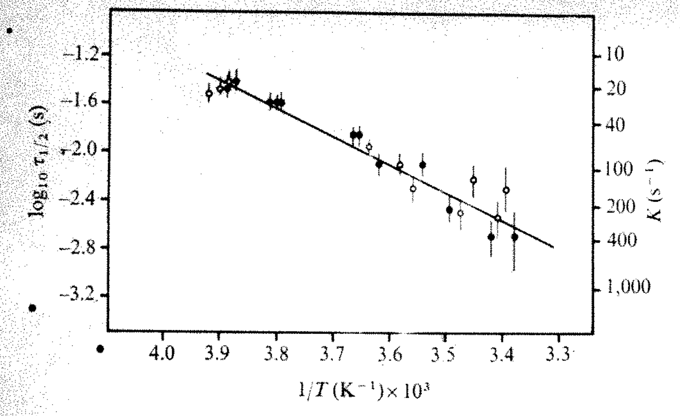

Fig. 4 Arrhenius plots of the half-times of MII formation (○) and of the BRT (●) for an edge-folded retina. The equivalent first order rate constant scale is on the right.

be associated with a lipid phase transition of the disk membranes, or to the gain of a negative one, we would expect to find some shorter wavelength at which the gain in birefringence due to loss of the anomalous dispersion effect would be just offset by the loss in birefringence caused by the achromatic component. This is in fact the case, as described above.

Although this analysis shows that the achromatic BRT cannot be attributed to a loss of the visual pigment anomalous dispersion effect, its millisecond relaxation time suggested that it is linked to the formation of the photoproduct metarhodopsin II (MII), which appears at a similar rate in solution[91]. To test this hypothesis we measured the half-times of *in situ* MII formation and of the BRT (Fig. 2) as a function of temperature, using edge-folded retina preparations mounted on a theromostatically controlled Peltier cooler on the microscope stage. Coincidence of the Arrhenius plots of these measurements is taken to support the notion that the BRT is closely linked to the formation of MII (Fig. 4). Formation of MII might only be a rate-limiting trigger, however, and the nature of its linkage to the BRT remained to be explored.

In studies on bleached ROS, Schmidt showed that the total static birefringence is the sum of two opposing components, the form and the intrinsic birefringence, $n_T = n_F + n_I$. A body constructed of layers of membrane alternating with cytoplasm must have a negative form birefringence, independent of considerations of molecular orientation, that is quantitatively predicted by Wiener's equation[20]:

$$(n_{\parallel} - n_{\perp})_F \equiv \Delta n\mathrm{F} = -[f_c f_m (n_m{}^2 - n_c{}^2)^2]/[2n_T(f_c n_m{}^2 + f_m n_c{}^2)] \quad (1)$$

where Δn_F is the form birefringence, f is volume fraction, n is refractive index and the subscripts m, c, and T refer to membrane, cytoplasm and mean index for the whole body, respectively. Schmidt reasoned that since ROS show net positive birefringence ($n_{\parallel} > n_{\perp}$), there must also be an intrinsic component that is positive and of greater magnitude than the negative form component. He concluded that the intrinsic component resulted from net orientation of the lipid hydrocarbon chains perpendicular to the plane of the membrane, giving a higher refractive index along the chains than perpendicular to them. This constituted the discovery of membrane 'crystallinity'.

From the Wiener equation it is easy to see that a small change in the cytoplasmic volume fraction, f_c, could cause Δn_F to change. This might be mediated by an MII-driven change in osmotic pressure of the cytoplasm secondary to ion flow or a chemical dissociation reaction. It has also been shown, using X-ray diffraction techniques, that at some time during the 4–8 h after bleaching, rhodopsin has sunk from a position of $\frac{1}{3}$ immersion to a position of $\frac{1}{2}$ immersion in the frog lamellar membranes[21]. Since the membrane refractive index, n_m, is due to both lipid and embedded protein, and the protein refractive index is higher than that of lipid, increased protein immersion on bleaching would cause n_m to increase at the expense of n_c. Wiener's equation predicts that such a redistribution of refractive index components would cause an increase in the magnitude of the negative form birefringence, again consistent with our measured result if this change were driven by the formation of MII. Alternatively, a change in disk membrane surface potential concurrent with MII formation such as could be associated with an ionic redistribution or the early receptor potential, might cause compression and/or expansion of the membrane or a Kerr effect dipole realignment, as has been postulated for nerve by Cohen *et al.*[2,6,7]. This could change n_m, f_m or both.

To determine whether ionic mechanisms might be involved in either osmotic or surface potential effects, we looked for the BRT in retinae immersed in Ca^{2+}-free, Na^+-free, K^+-free and Cl^--free media and in media containing tetrodotoxin or ouabain. The BRT during all these treatments was indistinguishable from normal. In addition, the BRT persisted in frozen (< −10° C) and in glutaraldehyde-fixed retinae. Clearly, the BRT is not dependent on shifts in water distribution or on ionic diffusion potentials, known to be important in nerve. We therefore ruled these out as causal agents.

To examine the possibility that the BRT is caused by rhodopsin sinking into the lamellar membrane concurrent with MII formation, we note the finding of Korenbrot *et al.*[22] that glycerol readily enters ROS and permeates the cytoplasmic space. Using the glycerol imbibition method, we did index matching experiments, analogous to those done by Blasie using X-rays, with the advantage of the millisecond time resolution of the birefringence measurement. Retinae or single ROS were equilibrated in a series of Ringer solutions containing increasing fractions of glycerol. Since the refractive index of glycerol is 1.47, the

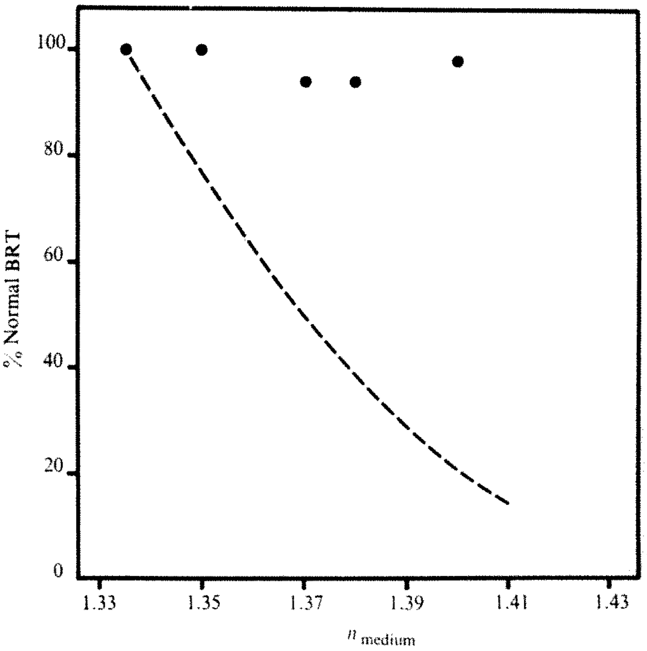

Fig. 5 Effect of glycerol imbibition on the relative magnitude of the BRT. Static form birefringence measurements indicate that, if the BRT was due to a change in form birefringence, the experimental points should lie on the dashed line. Lack of dependence of the BRT on imbibing medium refractive index, n_{medium}, shows that the achromatic BRT is due to a loss of intrinsic birefringence.

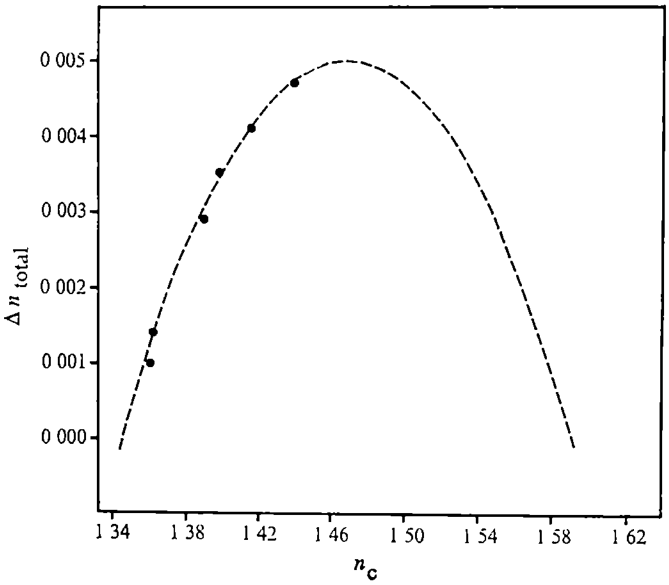

Fig 6 Static birefringence imbibtion curve of single ROS Experimental points (●) lie on a plot of the Wiener equation for which the following best fit values have been used n_m=1 475, n_c=1 365, f_m=0 37 and f_c=0 63 The curve shows that the net static birefringence of +0 0010 in Ringer solution is the sum of +0 0050 intrinsic component and a −0 0040 form component

effect of these treatments was progressively to diminish refractive index contrast between membrane and cytoplasm as the cytoplasm index increased If the BRT is caused by refractive index redistribution due to sinking of part of the rhodopsin molecule from cytoplasm to membrane, the influence of this redistribution should be diminished as the cytoplasmic index increases, up to the point were the index of the cytoplasm (glycerol) matches that of the non-rhodopsin part of the membrane At match, a sinking rhodopsin can only move between two media of identical refractive index and its effect on the birefringence should then be eliminated The results of these experiments show that the BRT is independent of the cytoplasmic refractive index and thus of the magnitude of the form birefringence component (Fig 5) This rules out the sinking of rhodopsin as a cause of the BRT More importantly it shows that the bleach-induced sinking of visual protein inferred by Blasie cannot occur on a time scale concurrent with visual excitation The hypothesis that visual protein might float on one surface of the membrane in darkness and then, on light excitation, sink to bridge the lipid phase with a pore, allowing Ca^{2+} to escape, is therefore not supported by our measurements

The experiments described here provide strong evidence that the achromatic BRT signals either lipid reorientation or a change in protein conformation, or both A small negative activation entropy calculated from our Arrhenius plots of MII formation argues against a sizeable membrane conformation change, although it is difficult to say how much would be enough It is also conceivable that compensating entropic changes occur in different parts of the lipid-protein complex, thus masking the true size of a conformational transition One of these changes might be optically anisotropic while the other is not

Birefringence and rod structure

We were able to learn something further of rod structure by measuring their static birefringence in glycerol-containing media of increasing refractive index The result (Fig 6) constitutes a so-called imbibition curve whose form is given by the Wiener equation As described above, glycerol imbibition allows the form birefringence to be eliminated progressively It not only unmasks the positive intrinsic birefringence previously compensated by the nearly identical negative form birefringence, but it allows the values of n_c, n_m, f_c and f_m to be determined From these measurements we find Δn_F to be −0 0040 for dark adapted *Rana pipiens* rods Since we measure the total birefringence of normal dark adapted cells to be +0 0010, the intrinsic birefringence, Δn_I, is +0 0050 Other values obtained by fitting the curve to Wiener's equation are n_m =1 475, n_c =1 365, f_m =0 37 and f_c =0 63 Since the refractive index for Ringer solution is 1 336, the value n_c =1 365 suggests that the cytoplasmic space contains about 16% solids, based on the mean refractive increment for sugars and proteins of ~0 016 per g % (ref 23) More than half of this value can be accounted for by protrusion of rhodopsin molecules from the membrane surface into the cytoplasmic space, while the remainder might be due to the protruding saccharide groups of glycolipids Cytoplasmic bridges between disk membranes have been reported[24], and similar structures have been postulated to account for the restorative force in osmotic shrinkage experiments on ROS[25] The cytoplasmic volume fraction, f_c, is in reasonable agreement with estimates of other workers[22,26]

It is useful to compare our value for the intrinsic birefringence of ROS, +0 0050, with that of myelin, +0 011 (ref 27) Although the two-fold difference suggests a more crystalline lipid order in myelin, it must be remembered that the large cytoplasmic volume fraction of ROS dilutes the measured membrane birefringence by more than a factor of two[28] Thus the true membrane value for ROS is about the same as for myelin In view of the higher degree of unsaturation of ROS membrane phospholipids[29,30] and low cholesterol content[31], this result is rather surprising and implies that ROS protein may impose a more crystalline order on the ROS lipids than would occur in an equivalent protein-free bilayer Alternatively, rhodopsin may itself be birefringent

Implications

If the BRT is due to a loss in crystallinity of the lipids of ROS membranes, it is interesting to learn what fraction of the total crystallinity it represents The ratio of the BRT to the intrinsic birefringence is about 1% when extrapolated to complete rhodopsin bleaching Since there are about 100 phospholipid molecules per rhodopsin in ROS disk membranes[32], the BRT could, therefore, be due to the disorientation of only one phospholipid molecule per rhodopsin bleached Alternatively, a small anisotropic change in protein structure as MII is formed might account for our results

On the basis of changes in ultraviolet absorption[33,34], ultraviolet circular dichroism[35,36], chemical reactivity[37,38] and molecular size[39] of detergent-solubilised rhodopsin, previous workers have concluded that a change in protein conformation accompanies bleaching Nevertheless, circular dichroism measurements on rod suspensions fail to confirm this evidence when rhodopsin is in its native milieu[40,41] Though flash photolysis measurements have been said to point independently to a conformation change during MII formation because of a large positive activation entropy found with this step[42,45] such measurements have been confined largely to detergent-solubilised rhodopsin or to suspensions of previously frozen or otherwise aged rod particles Contemporary evidence suggests that both these conditions alter the activation parameters found in fresh material[46] and we in fact find a negative activation entropy in our work on fresh rods Thus, it is difficult to judge the significance of either the very specific assays of conformation change such as circular dichroism or of the less specific activation energy analyses for our work In seeking an explanation for the BRT in intact retinae, however, it seems that a change in protein conformation must occur, for without such a prime mover, there would be no evident trigger for a lipid reorientation. On the other hand, if the BRT does not signal lipid reorientation, it must be directly detecting a protein conformation change.

There is keen interest in the use of biophysical techniques to detect and identify dynamic properties associated with physiological function of cell membranes or their isolated constituents. The ideal detection technique would be sensitive, time resolved, and specific for a particular molecule or molecular property. Measurements would be possible on intact cells without significant perturbations in structure through introduction of extrinsic probes. Needless to say, the ideal does not exist in a single technique and choice is frequently dictated by problems peculiar to each tissue.

Though it is easy to fault birefringence analysis on the basis of poor specificity, we have found in its application to rod outer segments a technique that is sensitive, time resolved, without perturbation and applicable to intact cells. In addition, specificity may be designed into the experiment. It has thus been possible for us to detect a membrane structural alteration in intact visual receptors that is specifically linked to one stage in pigment bleaching and that is fast enough to be associated with visual excitation.

Large outbursts in Cygnus X-3

Two radio outbursts in Cyg X-3 were observed during December 1973 and January 1974. The source was observed at 4.2 GHz using the 26-m radio telescope of Kashima Branch of the Radio Research Laboratories, which has a half power beamwidth of 10 arc min. Flux densities were obtained using drift scan so as to avoid interference from HII regions surrounding Cyg X-3. An average of four or five scans was taken to determine the flux densities. The receiver gain was calibrated during each determination using the output from a noise tube. It was also calibrated at five hour intervals by observing 3C147 (assumed flux density 9.3 Jy—1 Jansky=1 f.u.—) and 3C274 (80 Jy) in December 1973, and 3C123 (19.0 Jy) in January 1974. We measured the total flux densities alternately in orthogonal planes of polarisation by rotating the polariser, except on December 23 and 24, 1973. On those occasions the flux densities were measured in only one plane of polarisation. The pointing accuracy was checked frequently by the scans with declination offset. The error in flux density is less than $0.3+0.05S_{4.2}$ Jy, where $S_{4.2}$ is the flux density at 4.2 GHz.

An outburst was first recognised at 2200 UT on December 23, 1973, with a flux density of about 6.5 Jy. On December

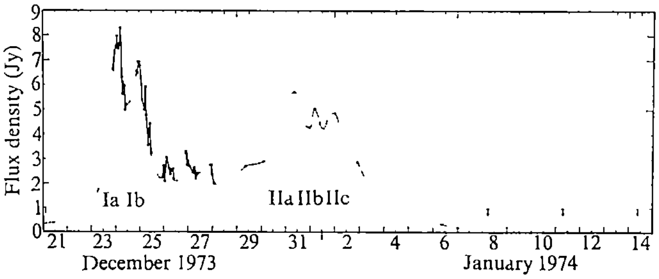

Fig 1 Observed variation in the flux density of Cyg X-3 at 4 2 GHz Peaks are numbered Ia–IIc

21 the flux density of the source had been less than the noise level (upper limit 1 Jy) Five hours after it was first detected, the flux density reached its maximum of 8 30 Jy (Fig 1) Seven days after the first event, a second outburst was observed The second outburst was observed only a few times a day

The two outbursts occurred about a week apart and both had a few peaks, each lasting about a day (Fig 1) Both of these features are similar to those observed during the outbursts of Cyg X-3 in September 1972 (refs 1–3)—before now the only large event known to have occurred on the source since its radio identification on July 19, 1971 (ref 4) It has, however, been monitored at intervals of a few months at Kashima since January 31, 1973, and except for this event, the flux densities have not exceeded 1 Jy

We thank F Takahashi and T Miki for their collaboration This work was one of the cooperative observations between Radio Research Laboratories, Japan, and the Tokyo Astronomical Observatory, University of Tokyo

Timing results for thirteen pulsars

As part of a continuing programme of pulsar timing measurements at the Arecibo Observatory, timing results have been obtained for thirteen pulsars following a year or more of observations at 430 MHz Precision timing results for these thirteen objects have not been reported previously The discovery names, references, and relevant least-squares fitting information are given in Table 1 The fitted parameters right ascension, declination, period (P) and period derivate ($\mathrm{d}P/\mathrm{d}t$) are listed in Table 2

The techniques used in the observations were basically the same as in previous work at Arecibo[1,2] Arrival times were determined by the template-matching method[2], the template in the present case being the sum of a large number of pulses processed by an incoherent de-dispersing device[3] The error bars assigned to daily average arrival times are the standard deviation from the mean of all the arrival times (usually ten or more) within the day Ephemeris corrections were carried out using data supplied by the Massachusetts Institute of Technology Lincoln Laboratory and were based on the work of Ash, Shapiro and Smith[4] The errors assigned to the fitted parameters in Table 2 are twice the formal standard errors resulting from the least-squares fitting process, the latter being computed according to Jurgens (unpublished) in order to reflect explicitly the value of χ^2

There are several aspects of the results which require comment Fits for several of the pulsars yielded a χ^2 rather small compared with the number of degrees of freedom The errors in the daily-average arrival times are apparently overestimated in these cases, perhaps as a result of 'pulse jitter' predominantly on time scales of several minutes The two pulsars PSR0611+23 and PP0943 behave in the opposite way, having a much larger value of χ^2 than expected It may well be that these two objects are further examples of pulsars exhibiting erratic behaviour in pulse phase on time scales greater than a few minutes, as do the Crab pulsar[5], PSR1642—03 and PSR0329+54 (ref, 17) Another possible explanation is in terms of the changes in pulse shape that are seen in averages of several minutes for both

Table 1 Information on pulsars for which timing results were obtained by least squares

*Errors in least significant digits are shown below each parameter

PSR0611+23 and PP0943 A quantitative study of this effect has not yet been made

Perhaps the most surprising results of these measurements are the unusually small values of dP/dt for MP1944 and JP1953, leading to the long 'lifetimes' of Table 1 According to our tabulation of dP/dt for 42 pulsars, dP/dt for MP1944 is about one order of magnitude less than the previous smallest value (AP2016—$dP/dt = 0\ 15 \times 10^{-15}$), and that for JP1953 may be two orders of magnitude smaller F D Drake (personal cummunication) has suggested that JP1953 may in fact be a white dwarf rather than a neutron star, but at present there seems to be no definitive way to confirm this possibility by calculation The total radio flux, an essential parameter in testing such a hypothesis, has, unfortunately, not yet been measured for either JP1953 or MP1944 Until more is known about the emission mechanism of pulsars, it will be difficult to decide on theoretical grounds whether or not JP1953 represents a new class of object

Effects of thermal photon scattering on relativistic electrons near pulsars

WE assume that pulsar radiation is generated close to the surface of a neutron star The production of this radiation clearly involves some sort of coherent motion of relativistic electrons, which are presumed to have been accelerated off the stellar surface by large electric fields along magnetic field lines of force Rengarajan[1] has pointed out that these electrons may scatter against black body photons emitted by the hot neutron star The hotter the star, the greater is the density of these photons, and the greater the probability that electrons will scatter against them Our purpose here is to examine the consequences of such collisions and the conditions required for them to take place

First, we find the limit on the neutron star temperature such that scattering occurs between a thermal photon and a relativistic electron Let $\mathscr{E}'$ be the energy of a photon in the rest frame of the electron, and $\mathscr{E}$ the corresponding energy in the rest frame of the neutron star We have $\mathscr{E}' \simeq \gamma\mathscr{E}$ and $\mathscr{E} \simeq 3kT$ where γ is the Lorentz factor of the electron, k is Boltzmann's constant and T is the surface temperature of the star Defining

$$\chi \equiv (2\mathscr{E}'/mc^2) \simeq (6\gamma kT/mc^2) \qquad (1)$$

(where m is the mass of the electron and c the speed of light), the cross section σ for electron-photon scattering is given by the Klein–Nishina formula[2]

$$\sigma = \begin{cases} \sigma_T & \text{for } \chi \ll 2 \qquad (2a) \\ 3/4\,\sigma_T \dfrac{(ln\chi+1/2)}{\chi} & \text{for } \chi \gg 2 \qquad (2b) \end{cases}$$

where the Thompson cross section $\sigma_T = 0\ 66\times 10^{-24}$ cm^2 The scattering cross section is Thompson if $\chi \ll 2$, $\chi = 2$ corresponds to $\gamma = \gamma_T \equiv 2\times 10^9\ T^{-1}$ If $\gamma \gg \gamma_T$, the scattering is Compton The number density of photons within a black body enclosure is 0 244 $(kT/hc)^3$, where h is Planck's constant, n, their number density just above the neutron star surface, is half this value The mean free path λ of an electron is then $\lambda \simeq (n\sigma)^{-1}$ for distances much less than the stellar radius

Regarajan estimates the critical temperature in order that mildly relativistic electrons scatter within about one stellar radius R from the surface With $\gamma \leqslant 10^3$ the scattering is Thompson or close to it, so that the condition that $\lambda \leqslant R$ is approximately given by $R \geqslant (n\sigma_T)^{-1}$ Thus he finds (using a slightly more rigorous method)

$$T \gtrsim R^{-1/3}\ 10^8,$$

which for $R = 10^6$ cm yields the limit $T \geqslant 10^6$ K, a very reasonable temperature for pulsars We will show, however, that such estimates are good only if the accelerating electric field strengths are unusually low

We now consider an electron accelerated by an electric field along a magnetic field line leading away from the surface of a neutron star If it scatters (against anything) and acquires a component of momentum across the magnetic field, it is then decelerated by the emission of synchrotron radiation The energy of such an electron in a medium with aligned electric (E) and magnetic (B) fields has an energy in time[3]

$$\gamma(t)mc^2 = mc^2[1-\beta_\perp^2(1-\beta_\parallel^2)^{-1}\exp(-2\Omega_B\delta s)]^{-1/2} \cosh(\Omega_B\alpha s+a) \qquad (3)$$

where s is the proper time given by $t = \int_0^s[\gamma(s')]^{-1}ds'$, and $\Omega_B = eB/mc$, $\alpha = E/B$, $\delta = \Omega_B\tau(1+\alpha^2)$, and $\tau = 3/2\ e^2/mc^3$ Here $\cosh a = (1-\beta^2)^{-1/2}$, where $c\beta_\parallel$ and $c\beta_\perp$ are the initial velocities parallel and perpendicular to the field For pulsar parameters $B = 10^{12}$ and $E \ll B$ we have $1 \gg \delta \gg \alpha$, the electron energy drops rapidly to $\mathscr{E}_{\min} = mc^2(1-\beta_\parallel^2)^{-1/2}$ in a proper time $s \sim (\Omega_B\delta)^{-1}$, and then begins to accelerate parallel to the field

Suppose first that the scattering is Thompson In Thompson scattering the energy of the photon is typically increased to $6\gamma^2kT$ This photon is emitted at an angle $\theta \sim \gamma^{-1}$ to the initial direction of the electron along the magnetic field The change in perpendicular momentum of the photon is then about $6\theta\gamma^2kT/c$ or $6\gamma kT/c$ The electron likewise experiences a change of perpendicular momentum $p_\perp \approx 6\gamma kT/c$ and its $\beta_\perp \approx 6kT/mc^2$ This momentum is non-relativistic so that the electron will emit cyclotron radiation at frequency[4] $\gamma\Omega_B$ From equation (3) we see that it will lose primarily only its perpendicular energy, which is small compared with its total energy, before being reaccelerated So the electron's motion along the magnetic field line is essentially unaffected by Thompson scattering (This discussion corrects that of Rengarajan[1], who erroneously concluded that Thompson scattering would drastically affect the electron's motion)

Secondly suppose that the scattering is Compton In Compton scattering the scattered photon and electron typically come out with about the same energy ($\sim 1/2\ \gamma mc^2$) at an angle $\theta \approx (6kT/\gamma mc^2)^{1/2}$ The electron's initial perpendicular momentum is about $p_\perp = (3/2\ \gamma kT/mc^2)^{1/2}mc$ and is relativistic ($\gg mc$) From equation (3) we see that its final energy before being reaccelerated, though relativistic, is now much less than its initial energy

$$1 \ll \gamma_{\text{final}} \simeq (\gamma mc^2/6kT)^{1/2}$$

For example, with $\gamma = 10^7$ and $T = 10^6$, $\gamma_{\text{final}} \simeq 10^{-2}\gamma$ Because the cross section for scattering (equation (2)) increases as γ decreases, the probability for scattering will again be greatly increased In fact the electron will Compton scatter again before it can recover its initial energy In this way the electron's energy will be progressively decreased until $\chi \simeq 2$, after which the scatterings are in the Thompson regime and the electron's energy will be only slightly affected by collisions

Compton scatterings will therefore limit electron energies in pulsar magnetospheres to $\gamma_T = 2\times 10^9T^{-1}$ Many people regard the radio emission from pulsars as curvature radiation In order for this to be so one requires $\gamma \geq 10^3$, which places an upper limit on the temperatures of the pulsars of about 2×10^6 K This limit, however, is only relevant if such scatterings do, in fact, take place This, in turn, is a question which depends on the specific structure of the pulsar magnetosphere, and we have been unable to come to any general conclusions with regard to it In what follows we will re-examine the conditions for scattering within the context of the pulsar model proposed by Sturrock[5]

Within Sturrock's model the electric field E increases linearly with distance r above the surface and is given by $E=3\times 10^2\,rP^{-1}$ statvolt cm^{-1} for $r \leq r_P \equiv 2\times 10^4\ P^{-1/2}$, where P is the pulsar's rotation period in seconds If the electron accelerates from rest at the surface it will have an energy $\gamma mc^2 = 1/2\ Eer$ at a height r, or $\gamma = \gamma_r = 10^{-1}r^2P^{-1}$ But in fast pulsars with $P \leqslant 0\ 7$ s, at a distance of $r_L = 3\times 10^4\ P^{4/7}$, the emission of curvature radiation slows the increase of energy, limiting γ to $\gamma_L = 10^7\ r^{1/4}$ for $r_L \leq r \leq r_P$ Finally, at heights $r \geq r_P$ the accelerating electric field presumably decreases with a scale height of about r_P The energy of the electron then rapidly decreases due to the continual emission of curvature radiation At about one stellar radius the energy reaches its asymptotic value given by $\gamma \simeq \gamma_\infty = 6\times10^7P^{1/3}$ for fast pulsars and $\gamma \simeq \gamma_{\max} = 3\times10^7P^{-2}$ for slow pulsars ($P \geqslant 0\ 7$ s)

The scattering cross section will be Thompson if $\gamma \leq \gamma_T$, that is at heights $r < r_T \equiv 2\times10^5T^{-1/2}P^{1/2}$ The condition that the mean free path $\lambda_T = (n\sigma_T)^{-1} \approx 10^{23}T^{-3}$ by less than r_T requires $T > T'$ where $T' = 2\times10^7P^{1/5}$ K This condition is more severe than that given by Rengarajan, because he required only that $\lambda \leqslant R \simeq 10^6$ cm Turning then to the Compton scattering limit $\chi \gg 2$ we have the mean free path

$$\lambda = 4/3\,\lambda_T[\chi/(ln\chi+1/2)] \qquad (4)$$

and $\chi = 6\times10^{-11}\ Tr^2P^{-1}$ for $r_T \leq r \leq r_L$ At $r = r_T$, $\lambda > r$, because $\chi \propto r^2$, λ increases faster than r Thus $\lambda \gg r$ for $r > r_T$ and electrons will never scatter in this regime For $r_L \leq r \leq r_P$ in fast pulsars the energy of the electron is ultimately radiation reaction limited, and $\chi = 10^{-2}Tr^{1/4}$ The mean free path then increases more slowly than r, but because $\gamma \gtrsim 10^8$ already, $\lambda \leqslant r_P$ only if $T \geqslant 10^8$ K Finally, beyond r_P, γ decreases and the scattering cross section increases The condition that $\lambda \leqslant R$ at $r = R$, where R is the stellar radius, is that

$$T^2 \ln(10^{-0\ 8}P^{1/2}T) \geq 10^{16}P^{1/3}$$

for fast pulsars and that

$$T^2 \ln(10^{-1\ 3}P^{-2}T) \geqslant 10^{15\ 6}P^{-2}$$

for slow pulsars Thus electrons will Compton scatter at least once if T exceeds $10^{7\pm0\ 2}$ K for $3\times10^{-3} \leqslant P \leqslant 3$ s

These limits for both Compton and Thompson scattering lie significantly above the observational upper limits on the temperatures of the known pulsars[6] The processes under consideration cannot, therefore, be occurring within them With regard to new pulsars, however, the situation is reversed, for the surface temperature of a newly-formed neutron star is very great By our analysis such a neutron star will be unable to generate curvature radiation (because of the low limits on γ) until it has cooled to below 10^7 K, a process which may take as long as several years Thus we conclude that very young neutron stars may not be pulsars

The above model conditions for scattering are, of course, dependent on the specific spacial structure and strengths of the electric fields that give rise to the radiating electrons The electric fields may in fact be much weaker than those chosen, thus less stringent (lower) limits on the temperatures are possible But in stars of low temperatures the photon-electron scatterings will have negligible effect on the coherence properties of the electron stream Therefore, it is doubtful that thermal photon collisions with the radiating electrons place any theoretical limits on the temperature of known pulsars

Dicarboxylic acids in the Murchison meteorite

INVESTIGATIONS of the extractable organic material found in the Murchison meteorite, a carbonaceous chondrite, have led to the identification of many different classes of compounds, including amino acids[1–5], hydrocarbons[3,6 7], heterocycles which contain nitrogen[8 9], and monocarboxylic acids[10] We report here a large suite of aliphatic dicarboxylic acids found in extracts from the chondrite This suite includes many of the branched and straight chained isomers with up to nine carbon atoms The large number of compounds and the isomeric distribution suggest that, like the amino acids, they are the product of an abiotic synthesis

The meteorite sample used for this study was prepared by removing the outer surface and reducing the interior piece to a fine powder with a mortar and pestle A hot water extract of a 2-g sample was obtained by refluxing for 20 h with 6 ml of water After centrifuging, the supernatant and subsequent wash solution were dried by rotary evaporation and redissolved in 0 5 ml of 0 09N HCl–methanol (The 0 09 N HCl–methanol solution was prepared by dissolving 0 36 ml of 12 N HCl in 48 ml of absolute methanol) The resulting solution was applied to a bed of clean, dry silica gel (0 9 cm by 10 cm) and eluted with 0 09 N HCl–methanol The first 3 0 ml of the eluate was collected, evaporated to dryness, and the residue taken up in 3 0 ml of 1 0 NCHl saturated with sodium chloride The solution was extracted continuously with diethyl ether for 18 h The ether extract was divided into three fractions The first fraction was evaporated to dryness and the di-(+)-2-butyl esters prepared by heating the residue for 1 h at 105° C with 1 ml of absolute (+)-2-butanol which was 8 N in HCl (ref 11) The second fraction was evaporated to dryness and the *n*-butyl esters prepared by heating the dry residue for 30 min at reflux with 1 ml of absolute *n*-butanol which was 1 25 N in HCl (ref 12) Similarly, the methyl esters were prepared by reacting the residue of the dry third fraction in methanol, with ethereal diazomethane

The di-(+)-2-butyl esters were separated by gas chromatography (GC) using a wall coated column of UCON 75 H-90000 (150 feet by 0 02 inch) The column was programmed from 100° C to 155° C at 1°C min^{-1} The same gas chromatograph was coupled to a mass spectrometer (MS) by means of a membrane separator, for GC/MS investigations A data system was used to acquire, store, and process the data The GC and GC/MS studies of the *n*-butyl esters and methyl esters were performed using a gas

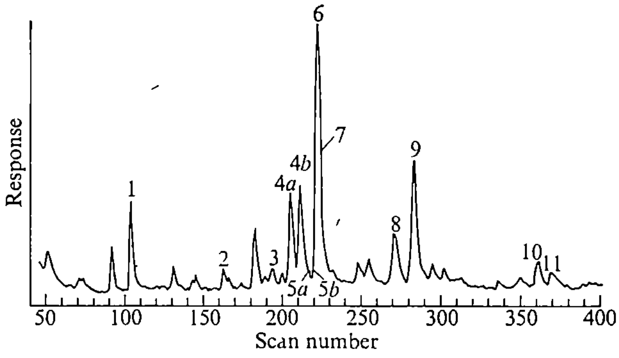

Fig. 1 Total ion plot, reconstructed by computer, of the di (+) 2-butyl esters of the dicarboxylic acids from the Murchison carbonaceous chondrite 1, Oxalic acid, 2, malonic acid, 3, 2,2-dimethylsuccinic acid, 4*a*, *b*, methylsuccinic acid, 5*a*, *b*, 2,3-dimethylsuccinic acid, 6, succinic acid, 7, fumaric and/or maleic acid, 8, 3-methylglutaric acid, 9, glutaric acid, 10, adipic acid, 11,3-methyladipic acid

chromatograph coupled by means of an all-glass membrane separator[13] to a mass spectrometer interfaced to a computer system The GC separations were carried out using a coiled-glass column (6 feet by 0 25 inch) packed with Tabsorb The column was programmed from 100° C to 210° C at 4° C $\min^{-1}$ Both mass spectrometers were operated at an ionising energy of 70 eV A procedural blank showed no dicarboxylic acids

The dicarboxylic acids found in the extract of the chondrite have been identified by their GC rentention values and by comparison of their mass spectra with those of authentic standards Thus, 17 dicarboxylic acids have been identified positively (Table 1) In addition, numerous other GC peaks were observed (Figs 1 and 2), many of which yielded mass spectra suggestive of the aliphatic dicarboxylic acids, but which, at this time, remain unidentified because of a lack of authentic standards

The presence of a large suite of dicarboxylic acids in carbonaceous chondrites has not been reported previously The isolated dicarboxylic acids consisted of a number of straight and branched chain isomers with up to nine carbon atoms All of the structural isomers of the dicarboxylic acids with two, three and four carbon atoms have been identified, and six of the eight possible structural isomers of the aliphatic dicarboxylic acids with five and six carbon atoms have been identified Many of the remaining isomers seem to be present, that must be confirmed by comparison with authentic standards The presence of a large number of isomers of the low molecular weight dicarboxylic acids is analogous to the distribution of amino acids found in this specimen of the Murchison meteorite (Pereira, W E , *et al*, unpublished), it is also analogous to the distribution of amino acids and monocarboxylic acids found in other specimens of the Murchison and Murray carbonaceous chondrites[1-5,10] The distribution of the aliphatic dicarboxylic acids suggests, therefore, that a random chemical synthesis may be responsible for their presence The state of all of the dicarboxylic acids in the meteorite sample is not known Whewellite, the calcium salt of oxalic acid has, however, been isolated and identified[14] Whether all of these compounds occur as salts or whether they are present as free dicarboxylic acids or some type of precursor to the dicarboxylic acids is unknown

Table 1 Dicarboxylic acids found in extracts of the Murchison meteorite

Oxalic acid
Malonic acid
2,2-Dimethylsuccinic acid
Methylsuccinic acid
2,3 Dimethylsuccinic acid
Succinic acid
Maleic and/or fumaric acid
3-Methylglutaric acid
Glutaric acid
Adipic acid
3-Methyladipic acid
Pimelic acid
Suberic acid
Azelaic acid
Methylmalonic acid
3,3-Dimethylglutaric acid
2,2-Dimethylglutaric acid

In addition to the saturated dicarboxylic acids, some unsaturated dicarboxylic acids were observed Mass chromatography has been used to detect an unsaturated dicarboxylic acid (maleic and/or fumaric acid) which elutes with succinic acid during GC analysis But maleic and fumaric acids have the same GC retention values on the columns which we used, and their mass spectra are virtually identical, so we were unable to distinguish between these two dicarboxylic acids in this investigation

In addition to the large number of structural isomers found in this sample, some of the dicarboxylic acids with asymmetrical centres show a GC separation of their enantiomers (see Fig 1) Although the separation of the optical isomers of amino acids has been accomplished by the preparation of the diastereoisomeric (+)-2-butyl derivatives, similar separation of the optical isomers of the dicarboxylic acids as the (+)-2-butyl diesters has not been reported previously A detailed investigation of the appropriate conditions, reagents, GC columns, and so on, necessary to derive these products, is in progress and will be reported in the future It should be noted that, in the manner analogous to amino acids obtained from abiotic sources, both enantiomers of R and S-methyl succinic acid seem to be present in nearly equal concentration (see Fig 1) A similar finding has been reported for a stimulated, abiotic, chemical evolution experiment[15] The continued investigation of the dicarboxylic acids is important because, apart from amino acids, they are the only other compounds so far found in meteorites in which the optical isomers have been separated The aliphatic dicarboxylic acids thus represent a potential suite of marker compounds for distinguishing between indigenous nonbiological and biological compounds found in extraterrestrial samples In addition, they are present in extracts of the Murchison meteorite at concentrations approximately one to two orders of magnitude higher than the amino acids The exact quantity and distribution of aliphatic dicarboxylic acids, when compared with similar information for amino acids and fatty acids, should provide insight into the organic reactions responsible for their presence in carbonaceous chondrites

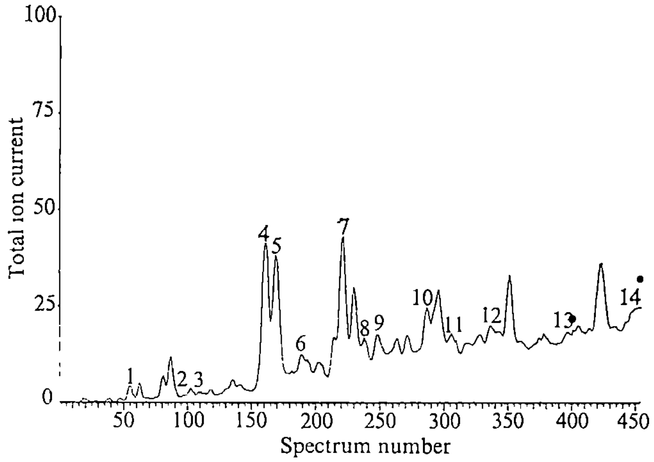

Fig 2 Total ion plot, reconstructed by computer, of the di-*n* butyl esters of the dicarboxylic acids extracted from the Murchison carbonaceous chondrite 1, Oxalic acid, 2, methylmalonic acid, 3, malonic acid, 4, succinic and maleic or fumaric acid, 5, methylsuccinic acid, 6, 2,3-dimethylsuccinic acid, 7, glutaric acid, 8, 3-methylglutaric acid, and 3,3-dimethylglutaric acid, 9, 2,2-dimethylglutaric acid, 10, adipic acid, 11, 3-methyladipic acid, 12, pimelic acid, 13, suberic acid, 14, azelaic acid

We thank the Smithsonian Institution for providing the sample (5455) used in this study The research performed by W E P , R E S , and A M D was supported financially by NASA

Dicarboxylic acids from electric discharge

OPARIN[1] and Urey[2] have suggested that methane, ammonia, hydrogen and water were present in the primitive atmosphere of the Earth Significant yields of amino, hydroxy, and monocarboxylic acids have been produced by the action of electric discharge on such a primordial gas mixture[3,4], and numerous chemical evolution experiments have produced many types of biologically significant molecules[5] Apart from the detection of succinic acid[3,4,6], no other dicarboxylic acids have been reported in chemical evolution experiments

A large suite of dicarboxylic acids, indigenous to the Murchison meteorite, have been identified, and they were probably produced in a random, nonbiological synthesis[7] As a result of this discovery, the possible synthesis of a similar suite of dicarboxylic acids was investigated in a chemical evolution experiment which simulated electric discharge through the primitive atmosphere of the Earth Among the products of this experiment, saturated, unsaturated, methyl and chloro-substituted dicarboxylic acids were detected, using gas chromatography (GC) and mass spectrometry (MS)

A 10-l electric discharge chamber equipped with four Tesla coils was used (see ref 8) A reaction mixture of 200 mm CH_4, 200 mm N_2, and 400 ml NH_4Cl solution (0 05 M, *p*H 8 77) was sparked for 48 h (ref 9) The aqueous phase was rendered strongly basic with NH_4OH, then filtered and stored in a freezer until the analysis Fifteen millilitres of this filtrate was concentrated to 5 ml by freeze-drying For the analysis, 0 5 ml of the concentrated filtrate was evaporated to dryness and redissolved in 0 5 ml of 0 09 N HCl in methanol (prepared by adding 0.36 ml 12 N HCl to 48 ml of absolute methanol) This solution was applied to a dry column (0 9 cm by 10 cm) of Adsorbosil-2, a silica gel without binder This adsorbent was batch-washed seven times with 0 1 N HCl in methanol, then dried and equilibrated to room humidity before use After the application of the sample, a 10-cm head of 0 09 N HCl in methanol was placed over the column and the chromatography was begun When the solvent reached the bottom of the column, nitrogen pressure was applied and fractions of 0.5 ml were collected The fractions were monitored using thin-layer chromatography The first 2 5 ml (containing the amino acids and dicarboxylic acids) were centrifuged to remove silica gel fines and then evaporated to dryness The residue was dissolved in 1 N HCl saturated with NaCl This solution was continuously extracted with diethyl ether for 16 h (to separate the amino acids from the dicarboxylic acids) The ether extract was dried, and diester derivatives of the dicarboxylic acids were prepared by heating the residue for 1 h, under anhydrous conditions, with (+)–2–butanol which was 5 N in HCl. Excess reagent was evaporated with a stream of dry, filtered nitrogen The di–(+)–2–butyl esters of the diacid were dissolved in 10 μl of methylene chloride A 2-μl sample of this solution (equivalent to 0 25 ml of the original electric discharge aqueous phase) was subjected to analysis by GC/MS A gas chromatograph was coupled to a mass spectrometer (operated at 70 eV) by means of a membrane separator A data system was used to acquire, store, and process the data No dicarboxylic acids were detected in the procedural blank Identification of the derivatised diacid electric discharge products is based on laboratory comparisons of their mass spectra with those of authentic standards Further confirmation was obtained by comparing gas chromatographic retention times of the products and standard compounds by co-injection techniques No significant racemisation was observed when R-methylsuccinic acid was run through the analytical procedure

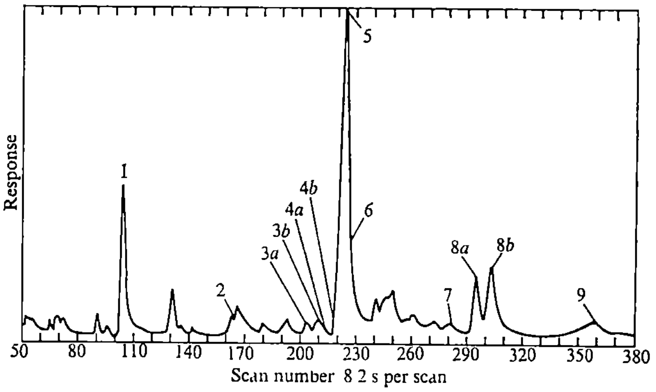

Fig 1 Gas chromatogram, reconstructed by computer, of the di–(+)–2–butyl esters of the dicarboxylic acid products of electrical discharge Identifying numbers as in Table 1 A wall coated column of UCON 75 H 90000 (150 feet by 0 02 inches) was temperature programmed from 100° C to 150° C at 1° C min^{-1} The helium flow was 5 ml min^{-1}.

Figure 1 shows the gas chromatographic separation of the derivatives of the diacids produced by spark discharge Table 1 lists those compounds that were confirmed by correlation of both chromatographic retention times and mass spectra with the corresponding authentic standards Mass chromatography was used to detect fumaric and/or maleic acid which elute with succinic acid The characteristic *m/e* 157 for succinic acid and *m/e* 155 for fumaric and maleic acid were monitored (Fig 2) These mass fragments correspond to the fragments of the respective derivatives minus one butoxy group Fumaric and maleic acid have identical retention times under the chromatographic conditions used and their mass spectra are virtually the same In a similar manner, mass chromatography revealed two peaks for the three possible configurational isomers of 2,3–dimethylsuccinic acid The use of optically active (+)–2–butanol to prepare diester derivatives of the diacids was necessary for the separation of those compounds containing asymmetric carbon atoms Enantiomeric pairs, such as R,S–methylsuccinic acid and R,S–2–chlorosuccinic acid, were separated using gas chromatography, with good resolution The exact order of elution of the enantiomers is under investigation in our laboratory, subject to the availability of pure, optically active standards

Table 1 Dicarboxylic acids identified as products of electric discharge

1	Oxalic acid	5	Succinic acid
2	Malonic acid	6	Fumaric and/or maleic acid
3*a*	Methylsuccinic acid*	7	Glutaric acid
3*b*	Methylsuccinic acid*	8*a*	2-Chlorosuccinic acid*
4*a*	2,3-Dimethylsuccinic acid*	8*b*	2-Chlorosuccinic acid*
4*b*	2,3-Dimethylsuccinic acid*	9	Adipic acid

* Elution order of configurational isomers is uncertain

Five of the eight possible structural isomers of the nonchlorine containing aliphatic dicarboxylic acids with two to five carbon atoms have been detected Furthermore, many of the unidentified peaks (Fig 1) have mass spectra suggestive of dicarboxylic acids Their identification is subject to the availability of pure standards The variety of structural isomers found is not surprising, because similar arrays of isomers arising from random chemical synthesis have been detected for hydrocarbons, amino acids, and monocarboxylic acids derived from chemical evolution studies[5]

The suite of dicarboxylic acids in the electric discharge experiment is similar to that of the Murchison meteorite, except for the fact that 2–chlorosuccinic acid is present in the spark discharge Because NH_4Cl was used in the experiment, chloro-acids were probably formed by the interaction of the discharge with aerosol particles suspended in the gas phase, or by interaction of chloride ions with reactive intermediates in the liquid phase, or both

Apart from work with amino acids[9], this gas chromatographic separation of R,S isomers represents the only case in which molecules possessing asymmetric carbon atoms synthesised in chemical evolution experiments were resolved chromatographically This gas chromatographic capability seems to provide a rapid, routine, new tool for the differentiation of biologically and nonbiologically produced dicarboxylic acids

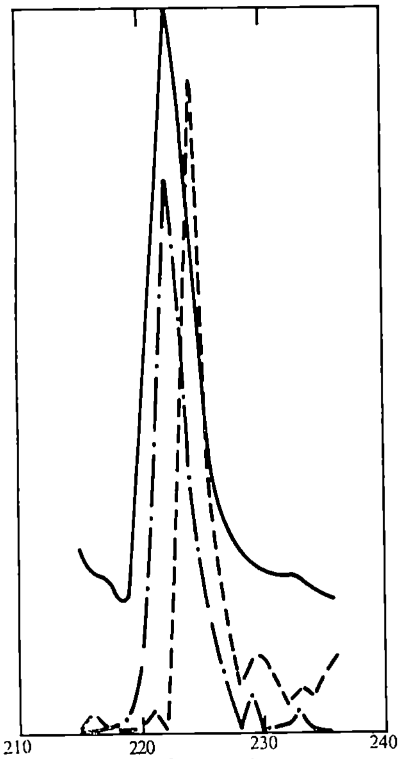

Fig. 2 Mass chromatogram, reconstructed by computer, of a portion of the GC/MS run shown on Fig 1 Solid curve, total ion current (scaling factor=1), dashed curve, $m/e=155$ (scaling factor=128), — — —, $m/e=157$ (scaling factor=16)

Dicarboxylic acids are important metabolic intermediates, especially with respect to photosynthesis and bioenergetics (as in Krebs cycle) The discovery that these compounds can be produced by spark discharge supports the view that dicarboxylic acids were probably present in the prebiotic *milieu* Thus, the abiotic synthesis of this class of molecules has implications for chemical evolution Because similar arrays of dicarboxylic acids, as well as amino acids[9,10], were found in the Murchison meteorite and the electric discharge experiments, it is possible that a high energy process such as electric discharge, played an important role in the production of the organic matter found in meteorites To explore this relationship, we are engaged in comparative studies of the organic and stable isotope chemistry of the meteoritic and synthetic products Such studies may shed light on the conditions of, and mechanisms involved in, organic synthesis in the early Solar System

We thank Steven Nitenson, College of San Mateo, for running the electric discharge experiments

Vertical mixing in the deep ocean

SEVERAL authors[1-3] have reported *in situ* observations of light scattering intensity in the deep ocean, which reveal the widespread occurrence of an ~ 1 km thick layer of suspended mineral and organic matter above the ocean floor The thickness of this nepheloid layer is several orders of magnitude greater than the characteristic thickness of the turbulent Ekman layer at the ocean floor[4] Analysis of observations of the nepheloid layer in the western North Atlantic indicates that an average vertical mixing coefficient, A, ~ 100 cm² s⁻¹ is required to maintain the layer[2] in the lowest kilometre or so of the ocean This value is significantly greater than the traditional (1 cm² s⁻¹) estimate based on water mass analysis[5,6] of vertical eddy diffusivity in the deep ocean

Here, I point out that this rather large mixing coefficient is consistent with mixing induced by internal waves[6,7] in the lowest kilometre or so of the ocean The relatively high vertical mixing rates in that region can be accounted for by the peculiarities of the generation of internal waves as a result of the interaction of topographic Rossby waves with relatively small scale ($\leqslant 1$ km) topographic features on the ocean floor

Following Bell[8], the rate of energy production in internal waves, E, arising from the flow of a steady uniform current, of speed, U, over a rough bottom, may be approximated as

$$E \sim 2\ \rho\ fNUH^2$$

where ρ is seawater density, f is the Coriolis parameter, N is the representative Brunt–Vaisala frequency, and H is the contribution to the r m s elevation of the topography in the internal wave passband of wave numbers, k, such that $f < kU < N$ In fact, deep ocean currents are not steady, being composed for the most part of tidal and inertial period motions and quasigeostrophic motions with periods of a week or longer[9] It is this latter component of flow which is relevant here The characteristic time scale for such motions is sufficiently large that they may be considered as steady as far as processes of internal wave generation are concerned

Swallow[10] has reported the results of a series of current measurements made during a period of 14 months in the western North Atlantic. The observed structure of the currents may be interpreted in terms of bottom trapped topographic Rossby wave modes[11], with velocity decaying on a vertical scale of several kilometres, from a near bottom maximum of roughly 10 cm s^{-1}. The presence of significant topographic structuring on horizontal scales of 10 km and smaller[12] should introduce further variability in the basic current field in the lowest kilometre. The interaction of this topographically modified quasisteady current field with the smaller scale topographical features is responsible for the generation of internal wave energy. As the internal waves propagate away from the bottom, the relative frequency, kU, decays with height. That has serious implications as far as the internal wave field is concerned. The ultimate catastrophe for any given wave component occurs when it encounters a critical level[13,14] at which the relative frequency is reduced to the local inertial frequency, f. Nonlinear effects inevitably destroy the internal wave component in the vicinity of such a critical level, so that as a consequence of the general decay of background current speed with distance above the bottom, a substantial portion of the internal wave energy should be dissipated in the lowest kilometre or so of the ocean.

The rate of production of internal wave energy may be estimated for conditions representative of the western North Atlantic. A typical deep current speed is, $U \sim 10$ cm s^{-1}. A representative value for the Brunt–Vaisala frequency is[15] $N \sim 7 \times 10^{-4}$ s^{-1}. Analysis of a large number of topographical profiles of abyssal hills in the eastern North Pacific[8] suggests that a value of $H^2 \sim 10^3$ m^2 is representative, and consistent with the results of an analysis of sonic sections[16] in the North Atlantic. At a latitude of 30° N ($f \sim 7 \times 10^{-5}$ s^{-1}), then, $E \sim 10$ erg cm^{-2} s^{-1}. If it is assumed that 50% of that energy goes into mixing in the lowest kilometre of the ocean, then there must be an associated buoyancy flux, F, $\sim 5 \times 10^{-5}$ cm^2 s^{-3}. With a Brunt–Vaisala frequency, N, $\sim 7 \times 10^{-4}$ s^{-1}, that implies a vertical mixing coefficient ($A = F/N^2$) of ~ 100 cm^2 s^{-1}. That is precisely of the same order as the vertical mixing coefficient based on the analysis of observations of the western North Atlantic nepheloid layer[2]. Further support of the proposed relationship between mixing induced by internal waves and the nepheloid layer is provided by the apparent correlation between bottom roughness and thickness of the nepheloid layer[3]. The mixing induced by internal waves discussed here must be balanced in the overall thermohaline energy budget. Acting over 50% of the North Atlantic, the vertical mixing estimate made here implies a rate of energy conversion of the order of 10^{18} erg s^{-1}. In this connection, Wright[17] has investigated the rate at which available potential energy is released by the sinking of cold water masses in the northern North Atlantic. He found that the two Norwegian Sea overflows, and winter convection in the Labrador Sea, contributed $\sim 0.85 \times 10^{18}$ erg s^{-1}. The North Atlantic seems to be somewhat unique in the intensity of its deep currents. Near-bottom currents of 3 or 4 cm s^{-1} are probably more representative of the world ocean[4], so that an estimate of E, ~ 1 erg cm^{-2} s^{-1}, with a corresponding mixing coefficient, A, of the order of 10 cm^2 s^{-1} may be considered as more representative of the world ocean.

Thermonuclear micro-explosions with intense ion beams

HIGH density pellet compression may be important in laser fusion[1]. In this way the minimum energy input for break-even can be substantially reduced to levels within reach of expected future laser technology. Further[2] when this concept is applied to a fissionable pellet surrounded by a small neutron reflector, preferably TD, which is compressed together with the reflector, to high densities, very small critical masses become possible, in addition the fission process could ignite a thermonuclear reaction in the TD reflector. In these proposals very large laser energies of ~ 1 MJ, which may be difficult to reach, are required. As an alternative to laser fusion I have proposed the use of intense relativistic electron beams[3], but here the beam pulse length is longer than for laser beams, and the electron stopping range may be too long.

I present here an alternative idea based on the possibility of generating intense ion beams in a magnetically insulated diode[4,5]. In such a diode a pulsed laser beam is directed on to the anode surface as a high voltage is applied to the diode, and a magnetic field directed parallel to the cathode surface prevents the flow of electrons from the cathode to the anode, but not the flow of ions from the anode to the cathode, provided that the magnetic field is strong enough to make the electron Larmor radius, but not the ion Larmor radius, small compared with the anode–cathode gap. The laser beam hitting the anode surface will produce a surface plasma from which the ions are drawn and accelerated towards the cathode. After their passage through the cathode, which has the form of a grid to minimise the energy losses by collision, the ions are projected into a drift tube. This drift tube is filled with a tenuous plasma of high electrical conductivity. Because of their large inertia the ions draw into their flow electrons which pass through the highly conducting plasma from the cathode surface or the inner surface of the drift tube. They thus compensate for an electric space charge field which would otherwise build up. Furthermore, because of their small mass and high mobility, the electrons will follow the ion flow with the same velocity, thus also cancelling the self-magnetic field of the ion beam entering the drift tube. The ion beam therefore drifts freely as an electrically and magnetically neutral beam.

Calculations for magnetically insulated diodes pulsed with several megavolt predict current densities of the order $j \sim 3$ kA cm^{-2} such that for an area of ~ 30 cm^2 a total current of $I \sim 10^5$ A could be produced[5]. To deliver a total energy of ~ 1 MJ with a voltage of $V \sim 10^7$ V and current of $I \sim 10^5$ A the total discharge time would be $\tau \sim 10^{-6}$ s. In order to take full advantage of the low ion velocities we may choose singly

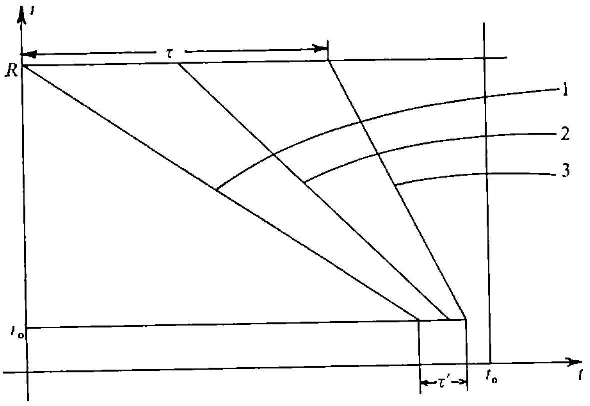

Fig 1 Time focusing of the beam

ionised heavy ions, such as ions of lead or uranium, with which the anode surface would have to be made or coated For a voltage V and atomic weight A, the ion velocity is given by $v \simeq 1\ 38 \times 10^6\sqrt{(V/A)}$ cm s^{-1} Putting $A = 200$ gives $v \simeq 10^5\sqrt{V}$ cm s^{-1} For $V = 10^6$ V, $v \simeq 10^8$ cm s^{-1} and for $V = 10^7$ V, $v \simeq 3 \times 10^8$ cm s^{-1} I propose that this variation of the ion velocity with the voltage may be used to focus the beam by increasing the voltage at the diode during the pulse Assume for example, that the pulse lasts $\simeq 0\ 7 \times 10^{-6}$ s and that an ion at the beginning of the pulse has a velocity of $\simeq 10^8$ cm s^{-1}, as compared with another ion at the end of the pulse with a velocity of $\simeq 3 \times 10^8$ cm s^{-1} One can then easily calculate that after the time $\simeq 10^{-6}$ s the ion emitted at the end of the pulse would have caught up with the ion emitted at the beginning of the pulse, at a distance of $\simeq$ 100 cm and time $\simeq 3 \times 10^{-7}$ s after the end of the pulse So by shaping the time behaviour of the voltage pulse properly at the diode one can make the ions converge at the same time and place, shortening the beam pulse and raising the beam power by perhaps many orders of magnitude

By making the ion source spherically symmetric and by projecting a beam of spherical symmetry towards a common centre of convergence, the total beam power density can be further increased This could be approximated by a large number of diodes in a spherically symmetric arrangement, with the diodes having a concave shape so that each beam pulse would have the form of a spherical segment

Figure 1 shows how the ion velocity would have to be changed in time during the pulse to focus the beam at time $t = t_0$ and at the common centre of convergence $r = 0$ The ions are emitted at the position $r = R$ The lines 1, 2 and 3 represent the $r - t$ diagram for the initial and intermediate and the final ion of the pulse Time focusing of the beam then requires for the ion velocity to follow

$$v = R/(t_0 - t) \qquad (1)$$

If a target to be bombarded by the beam is placed at $r = r_0$, the pulse length at the target τ' (at which $r = r_0$) is then shortened in comparison to the pulse length at the source (at which $r = R$) by the factor $\tau'/\tau = R/r_0$

It follows that for an ion velocity of v and a pulse length τ a linear beam can be focused in time after a distance $x \sim v\tau$, with a beam energy $E \sim IVx/v$ For $I \sim 10^5$ A, $V \sim 10^7$ V and $v \sim 10^8$ cm s^{-1} it follows that $E \sim 10^4 x$ J Therefore, for $x = 10^2$ cm, with $\tau \sim 10^{-6}$ s one would have $E \sim 1$ MJ and for $x = 10^4$ cm with $\tau \sim 10^{-4}$ s one would have $E \sim 100$ MJ A drift tube 100 m long is still well within the technical possibilities and the energy of 100 MJ to be pumped into the beam could probably be supplied by an inductive energy storage system But the energy stored in the drift tube can be delivered in a much shorter time depending on the perfection of the time focusing, which depends on the velocity spread of the ions Since the ions are produced from the anode material by a pulsed laser beam, two types of velocity spreads will occur first, by a differing degree of ionisation, second, by the initial thermal motion It is conceivable that by a properly chosen laser frequency a high degree of uniform ionisation can be achieved The most important velocity spread therefore results from the initial thermal ion energy at the anode surface This energy is of the order 1 eV In the anode–cathode gap the ions are then accelerated by a voltage of $\sim 10^6$–10^7 V, which for singly ionised ions implies an energy of $\sim 10^6$–10^7 eV Therefore, the beam will be monoenergetic to the order $\sim 10^{-6}$ to 10^{-7} corresponding to a relative velocity spread of $\sim 10^{-3}$ to $10^{-3\ 5}$ Thus, a time focusing of the beam by the same factor will be possible This would imply, for example, that in the case of the 100 MJ beam the energy could be delivered in a time of about $\sim 10^{-7}$ to 3×10^{-8} s, thus raising the beam power to 3×10^{15} W

Because of the pulse shortening by time focusing which is possible because of the low ion velocities, energy can be pumped into the beam slowly by inductive energy storage devices pulsing the diode Since the peak voltage is several million volts, this might be done with a cascade of pulse transformers

The range of heavy ions in dense matter is rather small (typically $\sim 10^{-4}$ cm), so the beam can be easily stopped if projected on to a solid piece of fusionable (or fission–fusion hybrid) material Furthermore, by properly shaping the time behaviour of the laser light impinging on the anode, the ion current and thus the beam power can be changed with time This is of importance if one wants to shape the beam pulse as has been proposed by Nuckolls *et al*[1] for adiabatic high density pellet compression with a power profile approximately given by

$$\varepsilon = \text{const}\ (1 - t/t_0)^{-15/8} \qquad (2)$$

It follows that the same power profile can be obtained with

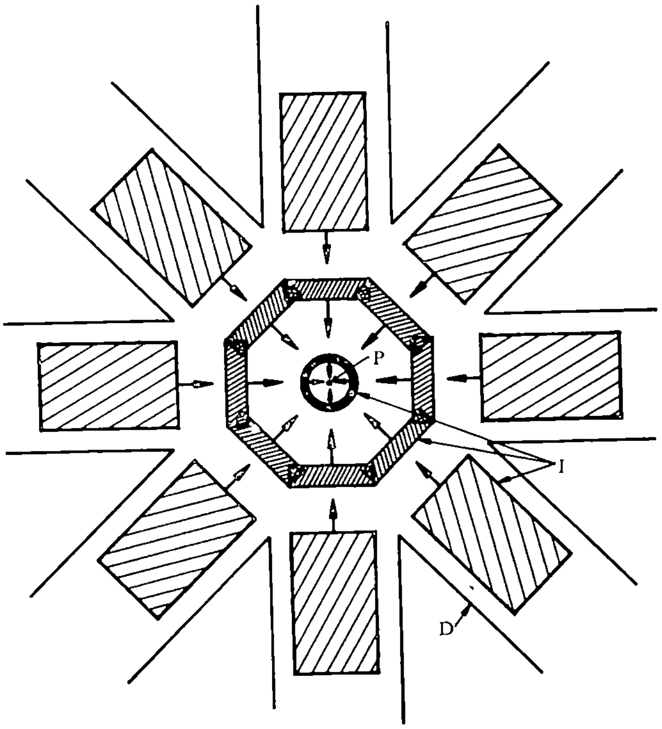

Fig 2 Coalescence and projection of several ion beams on to a thermonuclear pellet I, Ion beam, D, drift tube, P, thermonuclear pellet

the proposed ion beam technique. If the accelerating voltage is V and the ion current I then

$$v = \text{const}\ \sqrt{V} \quad (3)$$

$$\varepsilon = IV \quad (4)$$

From equations (1–4)

$$v = \text{const}\ (1 - t/t_0)^{-1} \quad (5)$$

$$V = \text{const}\ (1 - t/t_0)^{-2} \quad (6)$$

$$I = \varepsilon/V = \text{const}\ (1 - t/t_0)^{1/8} \quad (7)$$

Since the ion current is approximately proportional to the laser light intensity, a simultaneous change in both the accelerating voltage and laser light intensity can produce the power profile equation (2).

The proposed technique offers two possibilities for nuclear micro-explosions.

First, the ignition of rather large micro-explosions with two beams of ~100 MJ produced in two ~ 100 m drift tubes clashing head on, compressing and heating between them a sandwich of dense thermonuclear or fission–fusion hybrid material. For fusion pellets a minimum energy of ~ 10^2–10^3 MJ and for hybrid fission–fusion pellets somewhat less energy would be here required. It is therefore conceivable that two beams each having an energy of ~ 100 MJ would suffice.

Second, the use of many beams approximating one beam of spherical symmetry and which are projected simultaneously into a spherical combustion chamber as shown in Fig. 2. There, after having entered the chamber, the different beam pulses would coalesce into one ion pulse having the shape of a spherical shell, the thickness of which would decrease with time as the pulse approaches the centre of convergence at which the pellet to be ignited is placed. For reactor conditions a total beam energy of ~ 1 MJ would be required, as in the case of laser fusion, but since the focusing here may not be as perfect as for optical radiation a larger input energy may be needed, this does not, however, seem to present a problem since the energy can be drawn from cheap inductive storage devices. The pulse length required for solid pellet heating is of the order ~ 10^{-8} s and less. If the pellet has the form of a spherical shell the pulse can be somewhat longer. So if the pulse is delivered from the diode in about ~ 10^{-6} s it has to be compressed by a factor ~ 10^3, shortening the pulse length down to ~ 10^{-9} s. This implies a radial beam compression from an initial beam width of ~ 1 m down to ~ 1 mm. It seems that there is a fairly good chance that this can be done.

Measurement of the speed of light

WE report here the completion of a determination of the speed of light at the National Physical Laboratory[1]. The value was obtained from the product of the measured frequency and the wavelength, determined through up-conversion, of the radiation from a CO_2 laser stabilised to the R(12) transition of CO_2 at 9.3 μm.

The frequency was determined relative to the caesium standard, using successive stages of harmonic multiplication and beat-frequency detection, with HCN and H_2O lasers used as transfer oscillators. The value obtained[2] was ν = 32,176,079,482 kHz, with a statistical uncertainty, σ_m, of 0.13 × 10^{-9}, and a systematic uncertainty of ± 0.7 × 10^{-9}. (The systematic uncertainty is less than that published previously, because only the reproducibility of the CO_2 stabilised frequency is considered, rather than the uncertainty of obtaining the unperturbed R(12) transition frequency.) The wavelength was determined using interferometric measurements on up-converted light at 0.68 μm and was related to the ^{86}Kr primary length standard, realised in accordance with the latest recommendations of the Comite Consultatif pour la Definition du Metre (CCDM). The value obtained[3] for the free space vacuum wavelength is λ = 9,317,246.348 pm, with σ_m = 1.14 × 10^{-9} and a systematic uncertainty of ± 1.4 × 10^{-9}.

The product of these results gives the value for the speed of light

$$c = 299{,}792{,}459.0 \pm 0.8\ \text{m s}^{-1}$$

The uncertainty (corresponding to ± 2.7 × 10^{-9}) is the arithmetic sum of the standard error of the mean (1.1 × 10^{-9}) and the total systematic uncertainty (± 1.6 × 10^{-9}). Each of these was derived by quadrature summation of the contributions from the frequency and wavelength measurements.

Our measurement may be compared with values derived from a frequency measurement, by Evenson *et al.*[4], of the methane stabilised He–Ne laser at 3.39 μm, and the wavelength measurements made in that and other laboratories. The available data was reviewed by the CCDM in June 1973, when the method of realising the metre through the ^{86}Kr source was reconsidered. It was decided that where asymmetry of the spectral profile is observed, the defined wavelength applies to a point midway between the peak and centre of gravity. Thus, the result of Evenson *et al.* becomes c = 299,792,457.4 ± 1.1 m s^{-1}. On consideration of wavelength measurements in four laboratories, however, the CCDM recommended[5] for general use, the value c = 299,792,458 m s^{-1}, with an uncertainty of ± 4 × 10^{-9} resulting from the uncertainties of the wavelength measurements.

The satisfactory agreement of our result with those based upon the 3.39 μm laser confirms both the recommended value for c and the reliability of frequency and wavelength measurement techniques involving infrared laser radiations.

Accurate wavelength measurement on up-converted CO_2 laser radiation

WAVELENGTH measurements, which are part of an accurate determination of the speed of light[1], have been made on the radiation from a carbon dioxide laser, stabilised to the R(12) transition at 9.3 μm by saturated fluorescence in an external CO_2 cell, which has a measured frequency[2] reproducible to better than one part in 10^9. The problems of a direct intercomparison of infrared and visible wavelengths were avoided by mixing the CO_2 radiation with light from a 10-mW He–Ne laser at 0.63 μm to give a difference frequency sideband at a wavelength of 0.68 μm. This mixing process, known as up-conversion, was performed in a cooled, single crystal of proustite[3,4]. The wavelength of the CO_2 radiation was then determined using the relationship $\lambda_{9.3} = \lambda_{0.63}/(1-R)$, in which it is assumed that c is the same for the two visible radiations. The wavelength measurements were thus of the ratio $R = \lambda_{0.63}/\lambda_{0.68}$ and the value of $\lambda_{0.63}$ with respect to the primary length standard.

The value of $\lambda_{0.63}$ was determined by observing the frequency of beats against a He–Ne laser stabilised by saturated absorption of iodine, which is reproducible to better than one part in 10^{10}. The $^{127}I_2$ wavelength has been determined with a precision of 4 parts in 10^{10} by direct interferometric comparison with the ^{86}Kr standard[5]. Measurements from five other laboratories give a mean value within 1 part in 10^9 of our determination[6].

The wavelength ratio, R, was measured using Fabry–Perot interferometers with silvered plates and interchangeable fused silica spacers which incorporated piezoelectric adjustments. Two interferometric techniques were used, the first, and less precise, used a pressure scanning system developed from the arrangement used previously for precision measurements of wavelength[5]. For this first set of measurements the 10-mW laser was stabilised by reference to a Lamb dip laser which was ultimately referred by beats to component 'h' of the $^{127}I_2$ stabilised laser (λ = 632,991,369.6 fm). Using a spacer of 187 mm we took 37 measurements. A further 11 were taken with a 15 mm spacer. These observations lead to a value for $\lambda_{9.3}$ of 9,317,246.33 pm, with an uncertainty of ± 0.06 pm ($\pm 7 \times 10^{-9}$), which is the linear sum of random and systematic uncertainties (Table 1).

Table 1 Uncertainties of pressure scanning measurement (parts in 10^9)

Observational statistics	
	σ_m
Determination of $\lambda_{633}(^{127}I_2)$	0.4
Determination of $(1-R)$	
Short etalon	2.8
Long etalon	3.1
Resultant σ	4.2
Estimated systematic uncertainties	
Drift of Lamb dip laser (± 1 MHz)	±2
Refractive index calculations	
Pressure (± 0.1 torr)	±1
Temperature (± 20 mK)	±0.5
Nonuniformity of illumination	±1
Chromatic aberration	±0.7
Quadrature summation	±2.6

In the second, more precise, interferometric method the Fabry-Perot enclosure was evacuated. The interferometer was used with servo control of its length so as to be at a maximum of an interference fringe for the standard laser radiation, which was component 'd' (λ = 632,991,178.3 fm) of the $^{127}I_2$ stabilised laser. Using electronic feedback control to the 10-mW laser, the wavelength of the up-converted radiation was adjusted so that its interference pattern was also at the maximum of a fringe. The beat frequency between the 10-mW laser and the $^{127}I_2$ standard was counted directly. This measurement replaces the fringe interpolation necessary with the pressure scanning system. Thirty observations of the beat frequency, each of duration 10 s, were combined to give a single measurement. Using an etalon 187 mm long, 30 measurements were taken. A further 11 were taken using an etalon 19 mm long. Combined, they give a value

$$\lambda_{9.3} = 9{,}317{,}246.348 \pm 0.024 \text{ pm}.$$

The uncertainty, corresponding to $\pm 2.5 \times 10^{-9}$, is the linear sum of random and systematic uncertainties (Table 2).

Table 2 Uncertainties of servolock measurement (parts in 10^9)

Observational statistics	
	σ_m
Determination of λ_{633} ($^{127}I_2$)	0.4
Determination of $(1-R)$	
Short etalon	0.84
Long etalon	0.66
Resultant σ	1.14
Estimated systematic uncertainties	
Drift of etalon length	
Short etalon	±0.6
Long etalon	±0.3
Nonuniformity of illumination	±0.7
Chromatic aberration	±0.7
Modulation of $^{127}I_2$ intensity	±0.7
Reproducibility of $^{127}I_2$ laser	±0.2
Quadrature summation	±1.4

Differences of interferometer length, resulting from defects of flatness and parallelism, coupled with differences in the uniformity of illumination from the two sources, are important causes of error in the intercomparison of wavelengths. We measured the effect in our instrument by passing light from the 10-mW laser directly through the optical elements and diffuser normally used for the up-converted radiation. Operation of the servosystem should then result ideally in a zero beat frequency. The actual beat offset was determined using bidirectional counting, and verified as mainly systematic (7 parts in 10^9) by interchanging the optical elements with those used for the standard. The uncertainty ascribed to modulation of the standard laser results from a possible discrepancy between the time averaged frequency and time averaged wavelength when third derivative locking[5] is used.

The value determined with the servolock system is regarded as the final result of these measurements. The pressure scanning result was significantly less precise, although in excellent agreement. The wavelength standard throughout was the radiation of the $^{127}I_2$ stabilised He–Ne laser. The wavelength values assigned to it are those measured here recently[5] and in accordance with the advice of the Comité Consultatif pour la Définition du Mètre[6], relate to the 'as maintained' metre at the National Physical Laboratory. As mentioned already, that wavelength measurement, which used the ^{86}Kr source, is in excellent agreement with those of other laboratories, so that the results reported here are in direct accordance with the metre as it is internationally realised.

A burner for mixtures of very low heat content

We must anticipate a growing demand in the future for the means to burn low grade fuels, and fuel/air mixtures which may not even be normally flammable. Upcast gases from coal seams, ventilation air from mines, exhaust gases from a wide variety of industrial processes, and lean methane/air mixtures from some fermenting wastes are examples.

When gases such as these are allowed to escape unburnt, some particularly undesirable pollutants are added to the atmosphere quite apart from the wastage of energy. The amounts are far from negligible: it has been calculated that the methane content of the ventilation air from mines would be sufficient[1] to supply alone the entire power requirements of colliery machinery in the UK.

The majority of our combustion systems, being mixing-controlled, are quite unnecessarily inefficient, polluting and archaic[2,3]. Even for premixed reactants, combustion theory has treated flame properties such as temperature in the reaction zone and thus burning velocity, flammability, and so on, in terms of the initial fuel/air ratio alone. Yet merely arranging for a variable amount of heat recirculation breaks this dependence[4]. Our present concern is the burning of very lean mixtures, and it has been shown[5] that the percentage of fuel required to render a mixture flammable, decreases almost linearly with initial temperature, for example, at −0.0045% per ° C for CH_4. A study of the rate of burning of exceedingly lean methane/air mixtures, heated by an external source, has shown[6] that preheating gases in a furnace to, for example, 1,000° C, would ensure the complete reaction of even 0.5% CH_4 in air within 10^{-3} to 10^{-2} s.

Providing this heating by the 'borrowing' of some of the product enthalpy, without simultaneous dilution of reactants by products, has been considered[4], and the beneficial effects on limiting burning rates and compositions, on pollutant emission, on fuel saving and on the efficiency of conversion to electrical power when the unconverted energy is incorporated in the heat recycle, have been calculated[7]. Although the feasibility of such a scheme was demonstrated experimentally, this was carried out using a counter current heat exchanger surrounded by a Dewar flask, all constructed in fused silica[7] which was too transparent in the infrared and somewhat removed from current practice. Calculations reveal that it is necessary to provide many surfaces between the combustion region and the ambient atmosphere, and the maximum possible heat exchanger area must be arranged so that a layer of cold reactants shields the device from its surroundings.

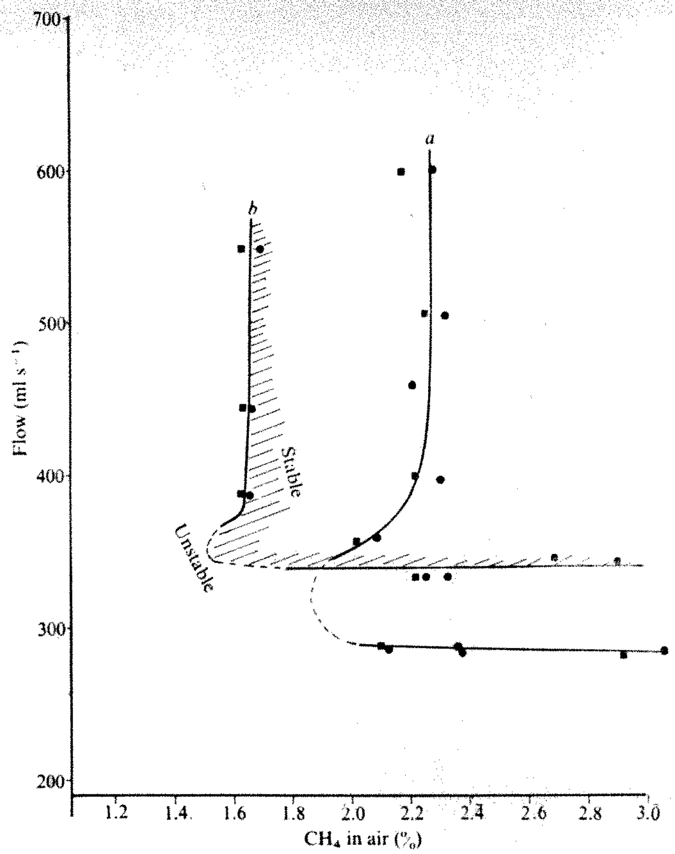

Fig. 2 Steady state stability characteristics of two burners as a function of mixture strength. Both burners are constructed of Inconel 600 strip 5 cm wide and the flow channel dimensions are 0.4 cm by 3.5 cm. *a*, 145 cm strip made into spiral of 4.5 turns; *b*, 229 cm strip made into spiral of 8 turns. ●, Stable flame; ■, unstable flame.
NOTE: The normal limit of flammability of methane is 5.3%.

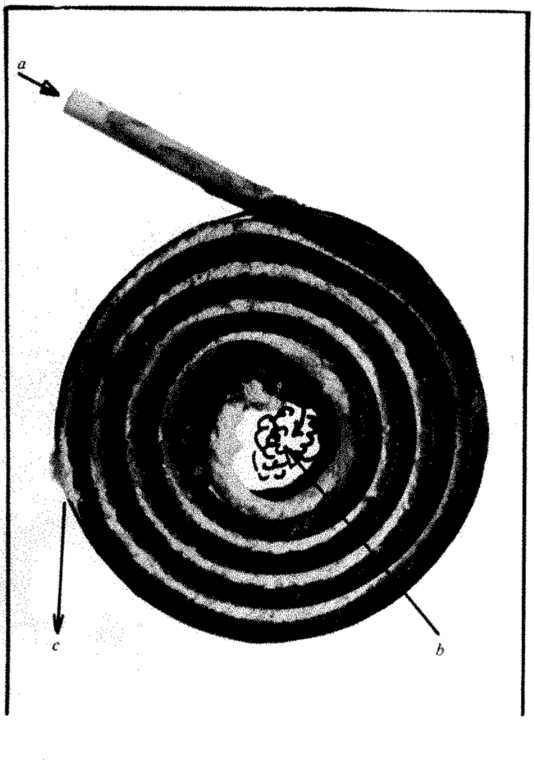

Fig. 1 Model of a burner of the type described in the text. *a*, Reactions (dark in simulation); *b*, combustion chamber; *c*, products (light in simulation).

Figure 1 shows a model of a slice of virtually the simplest device which combines these attributes. The cylindrical geometry of the burner is a compromise between the theoretical ideal of spherical symmetry on the one hand and reasonable ease of construction on the other. The experimental burners were readily constructed of strips of high temperature metal alloys (Inconel 600, Nimonic 75) by winding the spirals on spacers situated at the flat ends, which were subsequently sealed with high temperature cement. For laboratory feasibility studies, relatively thin slices (less than 5 cm open channel width) were deemed adequate. Thermocouples, igniters and any other instrumentation could be inserted before sealing instead of taking the leads out in between the spiral layers. Thermocouples at the inlet and outlet of the combustion chamber allow the position of the flame to be monitored, and indicate the amount of preheat and the heat release by combustion. A thermocouple at the exit allows the assessment of total heat losses when the exit enthalpy is compared with the chemical energy fed in. Certain ceramic materials also lend themselves to this form of construction, and would be suitable if very much higher temperatures are required.

Preliminary results were obtained with combustion chambers consisting simply of a cavity at the centre of the spiral. The reactants enter it through apertures in the cen-tial fold of the metal strip As with any other type of burner, the flame is stable for a limited range of flow rates, one difference which arises, however, is that blow-off, consequent on too high a flow, or flash-back, which occurs when the flow is too low (that is equivalent to premature ignition) decreases the effective length of the heat exchanger by moving the flame away from the centre of the spiral This introduces an automatic self stabilising mechanism against flash-back Figure 2 shows two limiting stability curves (flow velocity against fuel/air ratio) illustrating the effects of varying the length of the strip and of the geometry of the combustion chamber Even with the present small sizes (see Fig 2) extended ranges of stable burning were obtained for mixtures of fuel content corresponding to 1/3 the normal limit of flammability, and a much smaller fraction of the leanest mixtures stabilisable on conventional burners At this point the amount of heat recirculated is more than double that released by the reaction

The potentialities of such devices range from burning up undesirable pollutants, through association with fluidised beds, to direct power generation The design in which a high temperature fluidised bed combustor contained in a thoria crucible is located at the centre of the spiral, permits heat removal at the maximum temperature either by radiation or by a heat pipe Association with Stirling motors seems promising Here again the ability to vary the bed temperature independently of the fuel/air ratio and the flow velocity, by varying the amount of heat recirculated, makes it possible to maintain the most desirable conditions within the combustor Thus, poor solid fuels could be burnt at the same time as lean gas mixtures are combusted, and temperatures can be maintained below values at which concentrations of NO become appreciable

No less interesting are the possibilities regarding the direct generation of electricity In the past, magnetohydrodynamic, calorelectric, thermionic and other schemes have been considered in the field of combustion[8], but with little success Several attributes of the present burners make it seem worth while to reconsider some of these schemes One such attribute is the automatic feedback of the unconverted heat to the incoming reactants Another is the convenient geometry of the burner (for example for the application of magnetic fields) and the very large area of metal which it maintains at a high temperature with the smallest possible input of fuel In the small experimental devices under test, the ratio of the surface area of the metal strip to the cross-sectional area of the duct is over 2,000 and a throughput of about 200 W maintains approximately 0 1 m^2 of metal at white heat There can be little doubt that a thermionic generator constructed in a shape suitable for this spiral burner would yield an excellent overall efficiency[7] with lean mixtures

We carried out a simple experiment at atmospheric pressure, based on the supposition that, as the paths which the charge carriers have to cross is only of the order of 4 mm, many electrons will remain unattached[8] We coated two small electrode strips, one with barium oxide (to emit electrons) and the opposite one with potassium chromate (the positive ions from which would help to neutralise their space charge) The strips were again separated with insulating spacers, surrounded by radiation shields to simulate the coils of the spiral, and heated to various temperatures by flame gases while the currents flowing between them, and the potential, were measured The current gradually decayed with time and there was an associated deposition (presumably from the potassium chromate) on the barium oxide Potentials were of the order of 0 6–0 8 V, and graphs of log (current density) against $1/T$ gave straight lines corresponding to an activation energy of $1\ 81 \times 10^5$ J mol^{-1} Maximum current densities extrapolated to zero time and a temperature of 1,200° C were about 200 A m^{-2} These current densities are of course orders of magnitude smaller than the least values that have, in the past, been considered necessary to render viable an evacuated diode thermionic generator Our objective was not to produce a generator but merely to illustrate the feasibility of the principle, no doubt many other coatings and systems would yield better results Even so, at 1,200° C the maximum initial power density of about 150 W m^{-2} could yield an output of several tens of watts if an appreciable area of our small experimental spiral were maintained at that temperature This is to be compared with an input enthalpy flow rate of 200 W already attained in our preliminary experiments When used in this capacity, the spiral would, in any case, be built up to a large diameter so that the exit temperature, after abstraction of electrical power, need not exceed that of the incoming gas by more than the very small amount required to drive the heat transfer

We therefore conclude that devices of this kind are not only capable of burning exceedingly lean fuel/air mixtures —well below the conventional flammability limit—but may, with some experimental refinements, also lend themselves to direct power generation from such mixtures

The stability of connected linear systems

GARDNER and Ashby[1] have given an account of the sudden onset of instability at a particular connectance in a set of N first-order linear equations, described by $\dot{x}_i = A_{ij} x_j$ They gave graphs for $N = 4$, 7 and 10, showing how the probability of stability varied with the connectivity, C, which was defined as the fraction of the coefficients A_{ij} $(i \neq j)$ allowed to be non-zero These couplings, A_{ij}, were uniformly distributed randomly between $+1\ 0$ and $-1\ 0$, and the diagonal terms, A_{ii}, were uniformly distributed between $-0\ 1$ and $-1\ 0$ This result seemed to be of great importance as a model for many real systems

As a preliminary to a study of the effects which it has been anticipated would occur if there were strongly local structure, we have repeated these calculations, but could not confirm the sharp, stepwise onset of instability Figure 1 shows our results compared with those of Gardner and Ashby[1]

Points were calculated by actually finding the eigenvalues and examining them for real parts equal to, or greater than, zero (using the Nottingham Algorithms Group subroutine for non-symmetrical real matrices) Figure 2 shows the low-connectivity region on an increased scale

R M May[3] examined the situation theoretically and concluded that the critical connectivity, C, is given, for sufficiently large N, by $a^2NC = 1$, where a^2 is the mean square value of the non-zero A_{ij} He finds that "the relative

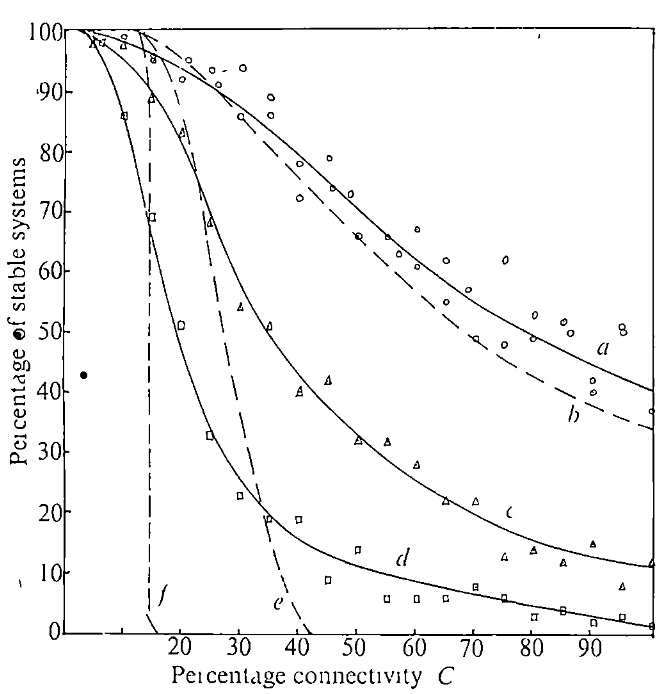

Fig. 1 Connectivity, C, against percentage of stable systems Each point corresponds to 100 randomly filled matrices, except in cases of $N=20$ Dotted lines, results of Gardner and Ashby[1], solid lines, our results a, $N=4$, b, $N=4$, c, $N=7$, d, $N=10$, e, $N=7$, f, $N=10$

width of the transition region, scales as $N^{-2/3}$"

From the slopes of the curves where they are roughly linear, we found that the width of the transition region (the inverse of the slope) is approximately proportional to $N^{-3/2}$ Ashby and Gardner[1] found a much steeper function, the width approached zero for $N = 10$

It seems that, given a number of systems which are stable in isolation from one another, increasing the connectivity (keeping equal probabilities of positive and negative couplings) simply increases the probability of instability All authors are agreed upon that general conclusion The conjecture of Gardner and Ashby, that the sudden change from stability to instability occurs at a certain critical nonzero connectivity, has not been confirmed Therefore, although earlier comments[2-4] on that particular step-like feature remain valid in their general analyses, they can be refuted once it has been shown, as it has been shown here, that the feature is an artefact of the computations of Gardner and Ashby[1]

Evolution of organic compounds in volcanic regions

According to Oparin[1], the origin of life is a natural consequence of the long evolution of organic compounds Much effort has been devoted to the abiogenic synthesis of biologically important compounds[2] but because little is known about conditions on the primitive Earth, the results of such experiments are inconclusive For this reason, the examination of volcanoes, hydrothermal systems and submarine volcanoes as sources of organic compounds seems to be highly promising

In fact, several theoretical[3,4] and experimental studies[5] have confirmed the thermal abiogenic synthesis of a wide range of organic compounds, and it may be possible to confirm the formation of organic compounds in volcanic regions

Amino acids and nucleic acid bases, such as adenine[4], can be easily synthesised in the presence of hydrogen cyanide, so the discovery of cyanide and thiocyanate compounds in areas of volcanic activity is essential if the volcanic model of the evolution of organic compounds is to be substantiated The results of examining volcanic material for the presence of some prebiological components (hydrogen cyanide and its derivatives) are given below In the search for these compounds some areas in Kamchatka and the Kuriles Islands are very suitable because intensive outbursts of juvenile material are observed in many eruptions there

From June to July 1973, the volcanic areas of the Kuriles (the Mendeleev and Golovnin volcanoes on Kunashir Island, the Alaid volcanoes on Atlasov Island) and Kamchatka (the Uzon, Malyi Semyachek and Mutnovsky volcanoes) were explored

Some thermal springs in the caldera of the Golovnin volcano (Kunashir Island) contain thiocyanates and hydrogen sulphide This indicates the primary formation of hydrogen cyanide with its subsequent transformation into thiocyanates Thiocyanates have been recorded previously[5] in other volcanic areas

In the water of several thermal springs in the caldera of the Uzon volcano (Kamchatka), cyanides were detected in the form of soluble ferrocyanides confirming some previous data[6] As might be expected, free hydrocyanic acid has not been found in these springs, because it is very reactive and because a large number of accompanying substances, such as sulphur in various stages of oxidation, are present

Free hydrocyanic acid can exist in active volcanic regions in conditions of fairly high temperatures and in the complete absence of substances that interact with it. Such conditions are found in the lava stream area on the Alaid volcano (the Kuriles) that erupted in 1972 and hydrocyanic acid was discovered in concentrations of the order of 0.01 mg l^{-1} in gas samples with a temperature of about 900° C that were taken from crevices in sheets of lava. The presence of the acid was determined by converting hydrocyanic acid to cyanogen chloride later identified using glutacondialdehyde (which forms a polymethine dye with 5,5-dimethyl-1,3-cyclohexane dionin) and also by the Berlin blue test. The presence of hydrocyanic acid derivates in volcanic exhalations has been noted before, but the detection of hydrocyanic acid proper calls for some additional discussion.

The character of the hydrogen cyanide detected is very important because it can also result, for instance, from a pyrolytic destruction of nitrogen-containing organic compounds. Nevertheless, the sampling conditions and the geological structure of the slag cone of the Olimpiiskii break (the site where gas samples were taken) in the Alaid volcano, point to the 'juvenile' character of recorded hydrocyanic acid.

The analysis of the volcanic gases and the temperatures indicate that hydrocyanic acid is a probable component of volcanic activity. The experimental data obtained can be considered as a confirmation of an earlier hypothesis about the role of volcanism (particularly submarine volcanism) and thermal springs in the processes of prebiological evolution on the primitive Earth.

Indeed, in strong eruptions, approximately 10^9 cubic metres of gas are released. If my results are correct, the amount of hydrogen cyanide liberated into the atmosphere in a single eruption would be about 10^7 g. Evidently volcanism must have played a significant role in the synthesis of organic compounds. Amino acids have also been detected in several thermal springs. But conclusions about the 'juvenile' nature of these compounds can be made only after undertaking additional investigations.

Experimental production of diabetes mellitus by a nonendocrinal approach

THE immunofluorescent demonstration of large deposits of fibrin in the microvascular lesions[1,2], and evidence of a slow consumptive fibrinocoagulopathy in maturity onset diabetes mellitus[3,4], suggested the possibility of a primary fibrinocoagulopathic vascular aetiopathogenesis of the disorder. The present work was undertaken to investigate the possibility of an experimental production of diabetes mellitus in animals by induction of slow consumptive fibrinocoagulopathy[5].

A batch of 14 rabbits, weighing 1.5–2 kg was studied. The animals were kept on a standard pellet diet of the following composition, crude protein, minimum 20.0%, ether extract, minimum 6.0%, crude fibrin, maximum 4.0%, ash maximum 8.0%, calcium, minimum 1.5%, phosphorus, minimum 0.6%, nitrogen-free extract 48.0%, metabolisable energy, 3,000 calorie kg^{-1}. Mineral stabilised vitamin A and D_3 (Roche), vitamin E, vitamin K, vitamin B_{12}, vitamin C, thiamine, riboflavin, pantothenic acid, niacin, choline chloride, folic acid and trace minerals (cobalt, copper, iron and mangaese) were also added to this formulation. The animals were fed wih 60 g of the pellet diet and 110 g of vegetables and clean fresh water daily.

The production of 'slow consumptive fibrinocoagulopathy' was achieved by intermittent administration of intravenous bovine thrombin (Upjohn, USA) in small doses. The optimum dose of thrombin was determined by trying graduated doses of bovine thrombin from 5 National Institute of Health (NIH) units to 13 NIH units.

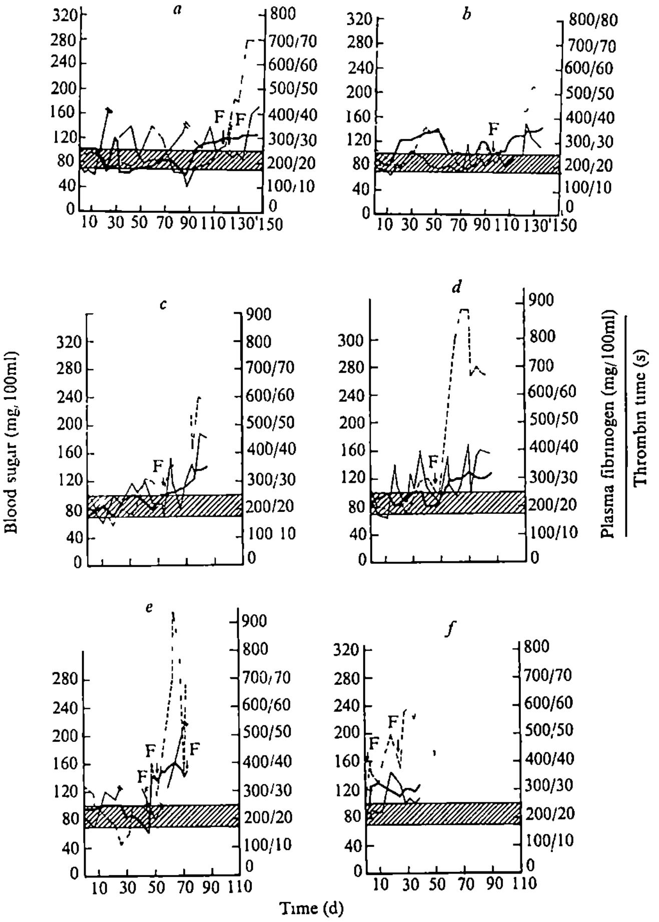

Fig 1 Blood sugar (▬▬), plasma fibrinogen (— — — —) and thrombin time (————) in six fibrinopathic diabetic animals. Shaded area shows the normal range (70–100 mg per 100 ml) of blood sugar. F, intravenous injections of bovine fibrinogen. *a*, Rabbit No 2, *b*, rabbit No 5, *c*, rabbit No 8, *d*, rabbit No 10, *e*, rabbit No 11, *f*, rabbit No 12.

While no significant alterations were observed with 5 NIH units, rapid deaths occurred with 12 and 13 NIH units. The thrombin dose was accordingly standardised at 10 NIH units, diluted in 10 ml normal saline, and administered at the rate of 1 U ml^{-1} min^{-1}. A faster rate of injection and higher concentrations of the thrombin solution produced fatal results. On this dosage schedule, it was possible to keep the animals alive in a state of fibrinocoagulopathy. The thrombin solution was routinely injected through the ear vein of the animals.

The haematological assessment for the fibrinocoagulopathic

Table 1 Results of experimental fibrinocoagulopathy in 14 animals

Rabbit No	Dose of thrombin administered	Rate of thrombin infusion	Haematological state	Clinical result
	1 Standarisation of thrombin dose and rate of infusion			
R_1	12 NIH/ 5 ml	1 ml min^{-1}	— —	Immediate death
R_3	13 NIH/10 ml	1 ml min^{-1}	— —	Immediate death
R_6	10 NIH/10 ml	Rapid injection (5 U min^{-1})	— —	Immediate death
R_9	10 NIH/10 ml	Rapid injection (2 U min^{-1})	— —	Immediate death
	2 Non fatal vascular complications			
R_7	10 NIH/10 ml	1 ml min^{-1}	Fibrinocoagulopathic state with prolonged thrombin time and reduced plasma fibrinogen (< 350 mg/100 ml)	Developed sudden hind limb paralysis after eleven injections without developing hyperglycaemia Experiment discontinued (blood sugar < 100 mg/100 ml)
	3 Experimental fibrinopathic diabetes mellitus			
R_2 R_5 R_8 R_{10} R_{11} R_{12}	10 NIH/10 ml	1 ml min^{-1}	Maintained 'Slow fibrinocoagulopathic state', with prolonged thrombin time and plasma fibrinogen above 350 mg 100 ml	Sustained diabetes mellitus (blood sugar 110–160 mg/100 ml)
	4 Central group			
R^4 R_{13} R_{14}	No thrombin injection, normal saline 10 ml injected intravenously		Normal thrombin time 20–22 min with 10 NIH units of thrombin and plasma fibrinogen 270–320 mg per 100 ml	Euglycaemic (Blood sugar 70–100 mg per 100 ml Mean 87 7 mg per 100 ml)

state was done by carrying out the thrombin time estimation by the method as described in our earlier communications[3-5], and plasma fibrinogen estimation as described by Ratnoff and Menzie[6]

After the initial induction of fibrinocoagulopathy, hypofibrinogenaemia was prevented in the animals by maintaining the plasma fibrinogen level above 350 mg per 100 ml, while on thrombin treatment, by periodic intravenous administration of 50 mg of bovine fibrinogen dissolved in 10 ml normal saline

The blood sugar estimation was carried out by the method of Asatoor and King[7] A batch of three central animals were kept on the standard diet schedule and received injections of the diluent normal saline used in the experiment A 'double blind' method with the coded blood samples, by two independant teams of laboratory workers, was adopted in carrying out the plasma estimations Results of the study of 14 animals are shown in Table 1 and in Figs 1 and 2

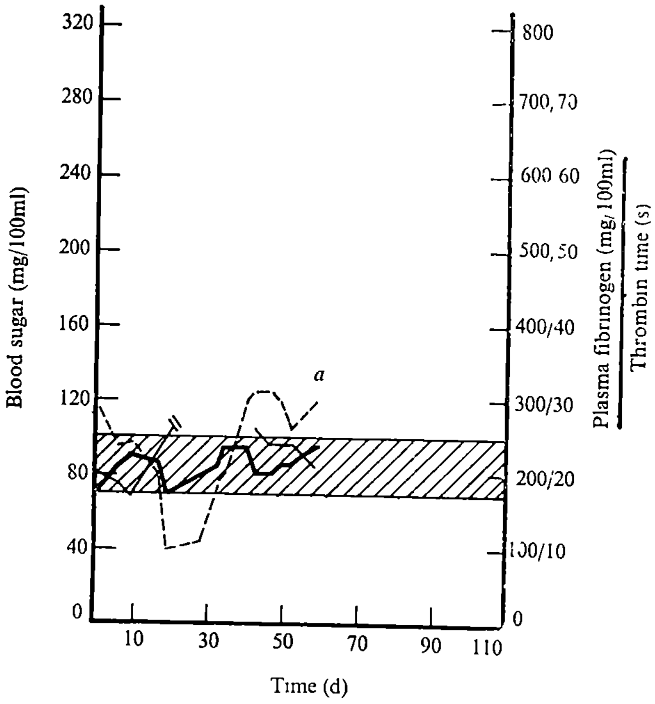

Fig 2 Blood sugar (▬), plasma fibrinogen (— — — —) and thrombin time (————) in animal R_7 Shaded area shows the normal range of blood sugar a, Acute spastic paraplegia

Our experimental procedure successfully developed a state of slow consumptive fibrinocoagulopathy in seven animals (R_2, R_5, R_7, R_8, R_{10}, R_{11}, R_{12}) and these were maintained in that state to study the alterations in the blood sugar level

In the three control animals (R_4, R_{13}, R_{14}), on scheduled diet regime, the blood sugar values ranged from 70 to 100 mg per 100 ml, with a mean value of 87 7 mg per 100 ml and the animals remained euglycaemic for the entire experimental period of 6 months, without alterations in the thrombin time or plasma fibrinogen level

In the experimental group, all seven animals showed an elevation in blood sugar values with the induction of consumptive fibrinocoagulopathy, in about 2–4 weeks' time The primary rise in the blood sugar levels, however, showed a decline with the hypocoagulability and reductions in the plasma fibrinogen concentrations In animal R_7, the primary elevation was within normal range, while the remaining six animals (R_2, R_5, R_8, R_{10}, R_{11}, R_{12}) became hyperglycaemic with values above 110 mg 100 ml

In all six animals (R_2, R_5, R_8, R_{10}, R_{11}, R_{12}) (100%), the hyperglycaemia could be reinduced by raising the plasma fibrinogen level above 350 mg per 100 ml, by supplementary injections of 50 mg of bovine fibrinogen Thereafter the animals remained diabetic, being maintained on fibrinocoagulopathic state with the plasma fibrinogen level above 350 mg per 100 ml (Fig 1)

Animal R_7, however, was not given any supplementary fibrinogen injection and the animal continued to be euglycaemic in a state of consumptive fibrinocoagulopathy till it developed acute spastic hind limb paralysis indicating a macrovascular occlusive lesion of the spinal artery (Fig 2)

In the case of R_{12}, the animal was given the supplementary dose of fibrinogen on the first day along with the primary dose of thrombin and developed a sustained diabetic state right from the very beginning, without showing any decline in the blood sugar values (Fig 1, R_{12})

The observations therefore provide convincing experimental evidence of a production of diabetic state by consumptive fibrinocoagulopathy in the animals The critical factor in developing the fibrinopathic hyperglycaemia seems to be a normal or raised plasma fibrinogen in a state of consumptive fibrinocoagulopaty in the animals As far as we are aware, this is first reported since the discovery of insulin, of an experimental production of diabetes mellitus by a nonendocrinal approach.

This work was carried out by grants from the Research and Development Organisation, Ministry of Defence, Government of India. We thank Brigadier S. Gopal Krishnan, Medical Superintendent, Safdarjang Hospital, for permission to carry out the experimental work. The technical co-operation and assistance of Subhash Chander and D. Das are gratefully acknowledged.

Mode of action of ancrod as a defibrinating agent

ANCROD is a thrombin-like enzyme obtained from the venom of *Agkistrodron rhodostroma*. When added to plasma, ancrod initiates fibrin polymerisation by the cleavage of fibrinopeptide A from fibrinogen[1] but activates factor XIII (plasma transglutaminase) very slowly[2]. Factor XIII, when activated, catalyses the formation of crosslinks between the α chains and between the γ chains of fibrin[3]. The absence of these crosslinked chains, especially the α chain polymers, allows fibrin to be easily degraded by plasmin[4,5]. Thus it is believed that ancrod acts as a defibrinating agent *in vivo* by producing non-crosslinked easily lysable fibrin deposits. We wish to present some preliminary evidence to show that commercial preparations of ancrod activate factor XIII in plasma *in vitro* and may also mediate the conversion of prothrombin to thrombin. In addition a hypothesis is presented to explain the defibrinating effect of ancrod *in vivo*.

Human fibrinogen (Grade L from KABI, Stockholm, Sweden) and bovine (Diagnostic Reagents, Thame, Bucks) or human (Parke-Davis) thrombin were used in these experiments. Human plasma was collected in 0.38% sodium citrate and stored in aliquots of 1 ml at −70° C when not used immediately. Hirudine, an inhibitor of thrombin activity, was obtained from Sigma, Surrey, and a naturally prothrombin deficient plasma was donated by Dr P. Barkhan (Guy's Hospital, London) through the offices of Dr M. Brozovic of this Institute. This prothrombin deficient plasma was immunologically and biologically devoid of prothrombin activity. Clinical grade ancrod (Arvin, batch F 1623) and a more highly purified extract (IRC 50 Arvin, batch DRP 1/143) were donated by Mr G. W. Tunnah of Twyford Laboratories, Beckenham, Kent.

Sodium dodecyl sulphate polyacrylamide (SDS–PA) gel electrophoresis was performed by the method of Weber and Osborn[6]. This technique has been successfully used to examine the subunit composition of the degradation products of fibrinogen by plasmin[7] and the degree of crosslinking of the γ chains and α chains of clotted fibrin[3]. Artificially made ($BaSO_4$ absorption) prothrombin-deficient plasma was treated separately with ancrod (40 Twyford units per ml plasma, 9 mM $CaCl_2$) and thrombin (2 NIH units per ml plasma, 9 mM $CaCl_2$) as was a 0.3% prothrombin-free fibrinogen solution (0.9% NaCl–0.4% Na citrate). After incubation at 37° C for 2 h the plasma fibrins were washed in saline–0.2 M ε-aminocaproic acid (ε–ACA) and reduced overnight in 4 M urea–1% SDS–0.2 M β-mercaptoethanol before examination by electrophoresis. The results are shown in Fig. 1. The γ chains are crosslinked and there are no α chain polymers in the Arvin-mediated plasma fibrin; however an α chain fragment of molecular weight 38,000 is evident (Fig. 1*a*)[1,8,9]. The IRC–50 Arvin-treated plasma fibrin was made up of β chains, γ dimers, some α polymers and some α chain fragments (molecular

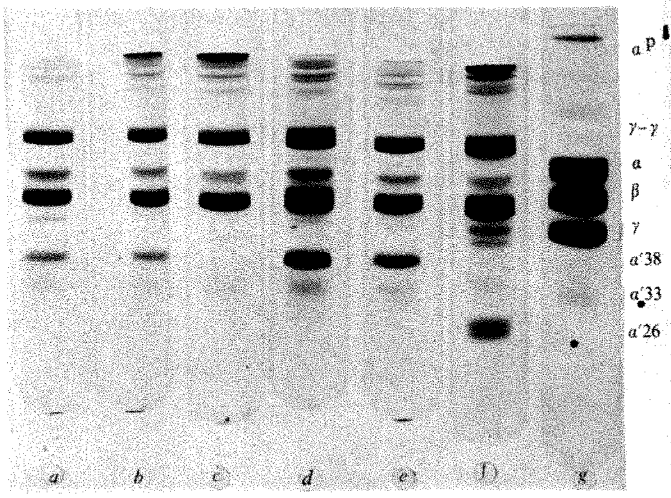

Fig. 1 Sodium dodecyl sulphate polyacrylamide (SDS–PA) electrophoresis (7% gel) of polypeptide chain subunits of fibrins obtained from plasma and from purified fibrinogen by treatment with ancrod preparations and thrombin. *a*, Plasma fibrin obtained by Arvin, batch F1623; *b*, plasma fibrin by IRC–50, batch DRP 1/143; *c*, plasma fibrin by thrombin; fibrins from purified fibrinogen by *d*, Arvin, batch F1623; *e*, IRC–50 Arvin, batch DRP 1/143; *f*, thrombin. Pattern *g*, show the three chains of fibrin α, β, γ. Electrophoresis was conducted for 16 h at 2 mA per gel. weight 38,000) (Fig. 1*b*). The thrombin–fibrin from plasma contained β chains, γ chain dimers and α chain polymers but no α chain fragments (molecular weight 38,000) (Fig. 1*c*). Figure 1 (*d-f*) shows that high levels of Arvin, IRC–50 Arvin and thrombin cause activation of factor XIII to crosslink most of the γ chains of purified fibrin; also that both ancrod preparations lyse the α chains of fibrin to form a 38,000 molecular weight fragment while thrombin does not. Thrombin produces some α chain fragments of molecular weight about 26,000 which have been described elsewhere[10].

Plasma naturally deficient in prothrombin was treated with a clinically used level of IRC–50 (0.07 Twyford units ml^{-1}) in the presence of 9 mM $CaCl_2$. Normal plasma, containing 250 units of Hirudine ml^{-1}, was treated with IRC–50 Arvin while normal plasma samples (1 ml) treated separately with 0.07 Twyford units of IRC–50 Arvin and 0.25 NIH units of thrombin, were used as controls. The fibrins were examined for their subunits on SDS–PA electrophoresis and the results are shown in Fig. 2. It is evident that Arvin IRC–50 by itself slowly activates factor XIII (as shown by the presence of some γ chain dimers) when there is no prothrombin present (Fig. 2*a*) or when thrombin is totally inhibited by hirudine (Fig. 2*b*). It is notable that at these concentrations of ancrod no α′ chain fragments (molecular weight 38,000) are produced and no α chain polymers are found during the 2 h incubation when the prothrombin–thrombin complex is absent or inhibited. In normal plasma (prothrombin present) the subunit pattern (Fig. 2*c*) with low level Arvin is the same as that obtained with thrombin (Fig. 2*d*). It can be seen that again there is no α chain fragment (α′ 38) formed while α polymerisation (α^p) is nearly complete. This suggests that the enhanced crosslinking induced by Arvin in normal plasma is a result of thrombin activation and that low levels of Arvin activate factor XIII slowly and do not lyse fibrin α chains. The α′ 38 fragment reported here (Fig. 1) and elsewhere[2,8,9] is an effect *in vitro* of high levels of ancrod and thus could play no part in the susceptibility of Arvin-fibrin to lysis by plasmin *in vivo* as has been suggested[8]. It is emphasised that calcium levels (< 9 mM) in these experiments were such as not to clot normal plasma during the course of these experiments.

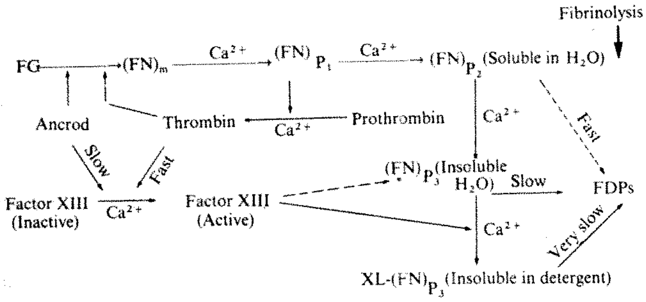

Fig. 3 Hypothetical scheme of ancrod generation of fibrin (FN) from fibrinogen (FG) *in vivo* and the ability of the fibrinolytic system to lyse the various possible fibrin polymers ($P_1 < P_2 < P_3$) to fibrin degradation products (FDPs). XL = crosslinked α chains and γ chains.

It is evident that low levels of the above ancrod preparations generate fibrin which is more rapidly cross linked in normal plasma than in plasma which does not contain prothrombin (Fig. 2). We suggest that by a mechanism as yet unknown these ancrod preparations may generate thrombin assuming that, in plasma, only thrombin can activate factor XIII. The proteolytic attack by ancrod on the α chains of fibrin (Fig. 1) does not occur at a low ancrod concentration (Fig. 2) and it can be shown that the α chains can crosslink slowly to α polymers. We have recently described[5], a fragment called D-dimer, which is formed during the lysis of fibrin clots and which contains the γ-γ crosslinks of the originating fibrin. This fragment has been also shown[11] to be released from crosslinked clots of whole plasma. But plasma from patients undergoing defibrination treatment with Arvin does not contain any of this D-dimer fragment (our unpublished results). The idea, based on *in vitro* evidence, that some soluble fibrin monomer complexes can be crosslinked by their γ chains[12,13] was not supported as we could not detect D-dimer in the plasmas of patients undergoing Arvin treatment. Since the deposition of fibrin and the formation of some γ-γ crosslinks take place at about the same time it seems that Arvin does not cause the deposition of fibrin *in vivo*. Instead fibrin, while still soluble, seems to be lysed by the fibrinolytic system in plasma.

The sequence of reactions outlined in Fig. 3 presents our current views on ancrod as a defibrinating agent, and other features of 'normal' fibrinolysis. Many aspects of this scheme need to be tested *in vitro* and *in vivo*. The main features of this hypothetical scheme are that fibrinolysis can most readily degrade soluble (under physiological conditions in plasma) fibrin polymers of size P_2 to fibrin degradation products (FDPs), that the 'lysability' of fibrin of an 'insoluble size' (P_3) and containing some crosslinks is decreased, and that totally crosslinked fibrin, XL(FN) P_3, is resistant to plasmin degradation to FDPs. It is proposed that an intermediate size fibrin polymer, $(FN)_{P_1}$ might be responsible for the activation of plasma prothrombin noted in the presence of ancrod preparations (Fig. 2). The suggestion that fibrin activates prothrombin has been expressed elsewhere[14], while both crude Malayan pit viper venom and a purified component of the latter can activate factor X[15,16]. The newly generated thrombin would then be available to augment the weak factor XIII activation potential of ancrod and would also explain why *in vivo* low levels of ancrod can defibrinate plasma so rapidly. The scheme also suggests that when normal fibrinolysis is depressed there is a greater probability of *in vivo* formation of fibrin deposits which may be crosslinked. Recent work[17] using the rabbit experimental model partly supports this aspect of the hypothesis. On the other hand it should be noted that Arvin, during infusion into man, has not caused[18] the deleterious side effects which might be expected from the *in vivo* generation of thrombin.

Differential effects of electrical stimulation on release of ^{3}H-noradrenaline and ^{14}C-α-aminoisobutyrate from brain slices

AMINO acids, especially γ-aminobutyric acid (GABA), glutamate, aspartate, glycine and taurine have been postulated to act as central neurotransmitters in vertebrates[1,2] Aside from GABA, which seems to have met the stringent criteria necessary for establishing its neurotransmitter role[3-6], the evidence for their role is mainly circumstantial Part of it is based on electrically induced release of amino acids from slices[7], chopped tissue[6,8,9] and synaptosomes[10] derived from different portions of the central nervous system In several of such studies, there are released not only the amino acids active as neuronal excitors (glutamate and aspartate) or inhibitors (glycine and taurine), but also amino acids with no known effects on the electrical activity of neurones such as lysine, arginine, leucine, cycloleucine, proline and glutamine[7,8] There is no criterion for believing that these last are transmitter susbtances

We have studied the conditions under which electrical stimulation is a valid method for releasing neurotransmitters from brain slices For this we have chosen to study simultaneously the efflux from neocortical thin slices of a known transmitter, ^{3}H-L-noradrenaline (NA) and a known amino acid non transmitter, ^{14}Cα-aminoisobutyrate (AIB) We repeatedly stimulated the slices electrically, with increasing intensities This we call the 'voltage profile' approach Both NA and AIB are actively transported into the cells by sodium-dependent processes NA by a specific transport system into noradrenergic cells[11], when its concentration is low (under 10^{-6} M), and AIB into both neurones and glia[12] through a transport system that shows preferential affinity for small neutral amino acids[13]

The release of ^{3}H-L-NA from unstimulated slices is similar to that reported previously for ^{3}H-DL-NA (ref 14) Two different first-order components may be distinguished A fast initial one represents the washout of extracellular NA, plus NA metabolities The second component is much slower and is believed to represent the efflux of NA from intracellular stores The efflux of ^{14}C-AIB follows a similar pattern, although the initial component is much less marked than that of NA, probably because of the nonmetabolisable nature of this amino acid

After the first efflux component became negligible (that is, after 40 min) the slices were stimulated with increasing voltages (Fig 1*a*) At low voltages (0 5–3 V), only ^{3}H-NA was released, in an amount roughly proportional to stimulus strength, at higher voltages the specificity of the response was lost, and both NA and AIB were released by electrical stimuli Under

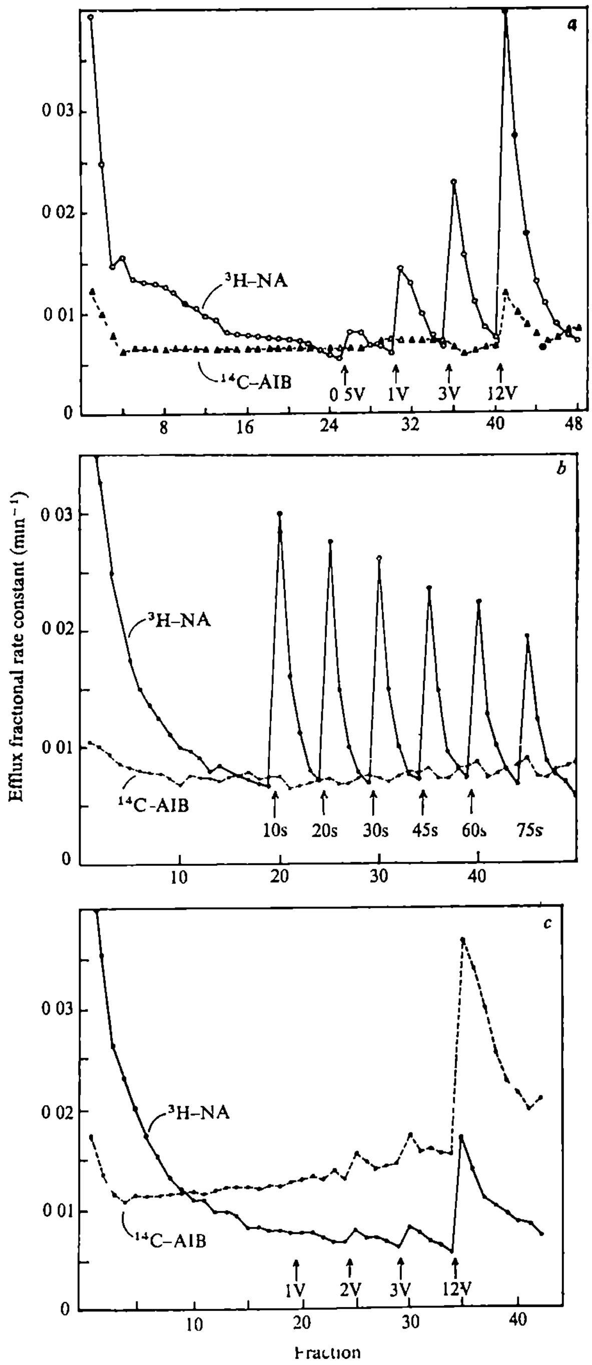

Fig 1*a* Electrically induced release of NA and AIB Slices were obtained from 120 to 150 g Sprague-Dawley rats, with blade and blade guide[15,16] Only the outermost slices were used Slices of both hemispheres remained attached and could be floated together The slices were initially incubated for 60 min in a Dubnoff shaker (37° C, 100 cycles min^{-1}) in 25 ml Erlenmeyer flasks containing 1 ml of a physiological glucose-salt solution[17], equilibrated with 5% CO_2 in O_2, and 7 8 × 10^{-7} M ^{3}H-L-NA (5 μCi, specific activity 6 4 Ci mmol^{-1}) and 10^{-4} M ^{14}C-AIB (1 μCi, specific activity 10 mCi mmol^{-1}) After this period, in which both NA and AIB were actively transported into the cells, the slices were floated into a McIlwain quick transfer electrode, and this was placed in a 30 ml beaker containing 4 ml of the same salt solution, but without ^{3}H-NA or ^{14}C-AIB The beaker was kept at 37° C in a thermoregulated water bath and vigorously gassed with 5% CO_2 in O_2 Every 2 min the fluid was aspirated with a 2 5 mm polyethylene tube connected at one end to a 3 mm Pyrex tube soldered to the bottom of the beaker, and at the other end to one of two perforations of a neoprene stopper fitted tightly to a 16 × 160 mm test tube The other perforation in the stopper connected the tube, through Tygon tubing and three-way valve, to a water pump After each aspiration the stopper was changed to a contiguous empty test tube The beaker fluid was replenished by means of an automatic syringe that aspirated the fluid from a reservoir and injected it, through latex tubing connections, to one of the two openings of a neoprene stopper placed on another 16 × 160 mm test tube, immersed in the water bath From this test tube, used for thermal equilibration, the fluid passed through a latex tube connected to a 3 × 80 mm Pyrex tube that was placed in the beaker The slice was stimulated with sine wave a c current, 50 cycles s^{-1}, obtained from the mains line and passed through two Variac variable transformers placed in series The stimulation voltage was monitored with a Tektronix model 532 oscilloscope, with its horizontal sweeping suppressed The voltage then appeared as a vertical line on the screen whose height represents twice the magnitude of the maximum instantaneous voltage (MIV) All voltages are expressed as MIV At the end of the experiment the slice was homogenised in 4 ml incubation fluid One millilitre of each collected fraction and 0 1 to 0 2 ml of the slice homogenate (with the total volume made 1 ml with incubation fluid), were counted with 10 ml of a mixture of toluene, containing 4% PPO and 0 05% POPOP, and Triton X-100 (2 1 v/v), in a two-channel liquid scintillation spectrometer Background substraction, and the calculation of ^{3}H and ^{14}C counts in each channel were performed with an IBM digital computer The efflux of ^{3}H-NA and ^{13}-C-AIB were finally expressed as efflux fractional rate constants[9] *b*, Slice stimulation with constant voltage and increasing times *c*, Stimulation in medium with no added calcium The initial incubation was done in normal glucose-salt solution, while the superfusion was in medium nominally without calcium In a second experiment, identical results were found, except that no NA or AIB were released with stimuli of 0 5 V, 30 s, or 2 V, 10 s

our experimental conditions, the limits between which electrical stimulation was a valid tool for neurotransmitter release was between 0 5 and 3 V (Fig 2) At and above 4 V, AIB, and probably all actively transported nontransmitter amino acids, are released

When the slices were stimulated repeatedly with 3 V for different lengths of time (Fig 1*b*), a progressive decline in the induced ^{3}H-NA efflux, quite analogous to synaptic fatigue became apparent With stimulation times longer than 30 s, small increases in AIB efflux could also be elicited In stimulated slices, the efflux of AIB assumed an undulating character, not seen in the absence of stimuli, that might be related to fluctuations in the concentrations of intracellular sodium

Markedly different results were obtained when the efflux of NA and AIB was studied in slices superfused with calcium-free medium (Fig 1*c*) The efflux of ^{3}H-NA did not increase when the slices were stimulated with 0 5 and 1 V, and the extra efflux induced by higher potentials was greatly reduced ^{14}C-AIB was however now released by stimuli as weak as 2 V, and at 12 V, its stimulated efflux is considerably larger than when calcium was present Independently of the stimulation voltage, the efflux of AIB also now showed a steady increase with time

The most straightforward interpretation of the electrically induced release of AIB is based on the sodium hypothesis[18] of active amino acid transport Release seen at high stimulation potentials is probably due to increased intracellular sodium[19] that enhances the affinity for AIB of the transport carrier on the inside of the membrane Similarly, it is known that in calcium-deficient media, sodium influx during stimulation is increased [20] This should also lead to an enhanced amino acid efflux during stimulation Finally, independently of stimulation, brain slices placed in media nominally without calcium[21] steadily increase their intracellular sodium[17] This correlates well with the steady increase in AIB efflux seen in calcium-free medium

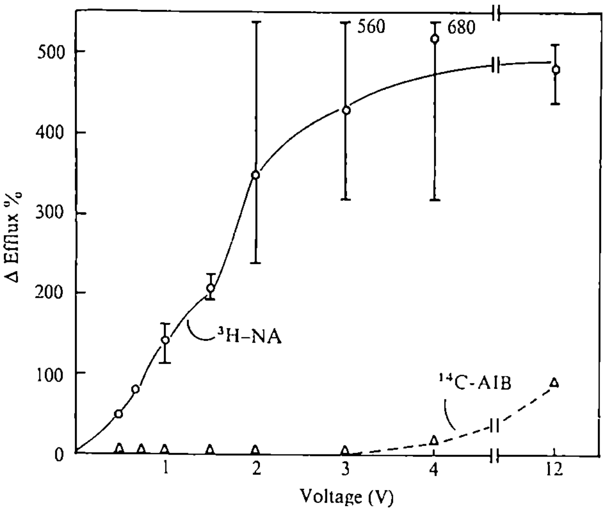

Fig 2 Differential effects of electrical stimulation on NA and AIB release Each point represents 3–5 estimations Ranges are shown as vertical lines All the triangles in the 0 to 3 V region have zero values

It seems likely that the electrically induced release of NA seen at low stimulating potentials is not immediately dependent on the reverse operation of a sodium activated, carrier mediated, transport system, but represents true calcium-dependent exocytotic neurotransmitter secretion With more intense stimuli, both calcium-dependent and sodium-dependent mechanisms may be set in operation The small electrically induced NA release seen in medium that lacks calcium could be interpreted as being due to the presence of residual amounts of calcium which still support some secretion But the strict parallel that exists under these conditions between the electrically induced release of NA and of AIB, strongly suggests that all of the NA released in the absence of calcium is due to the reverse operation of the sodium-activated NA membrane transport system The source of NA is presumably free NA present in the cytoplasm The coexistence of sodium-dependent and calcium-dependent neurotransmitter release processes, in these *in vitro* preparations, with a great enhancement of the sodium processes when no calcium is present, makes it very difficult to demonstrate an absolute calcium requirement for neurotransmitter release For this, stimulation conditions must be very carefully controlled, and there should be internal controls for sodium-dependent processes, as is the case with AIB efflux

The voltage profile approach is essentially a qualitative procedure, by which substances released by electrical stimulation may be classified as neurotransmitter-like or amino acid-like, the actual amount of substance released is, in itself, irrelevant for this classification This approach may be applied to any of the various systems used for superfusing and stimulating nerve tissue preparations *in vitro*, although the stimulation parameters will vary considerably from one system to another Its use will determine whether many of the substances reported to be released by electrical stimulation behave in a transmitter-like or in an amino acid-like manner This approach may however only be used with stimuli of alternating polarity, because monophasic pulses rapidly polarise the electrodes

We are grateful to Mr P Frigerio for constructing the quick transfer electrodes, to O Petit for technical assistance, to E Moraga for the computer program and to Conicyt and Comisión de Investigación Científica, Universidad de Chile, for financial help

Insulin unmasks latent sodium pump sites in frog muscle

INSULIN stimulates the movement across the cell membrane of a variety of substances such as glucose[1], amino acids[2], and alkali cations Na^+ and K^+ (refs 3 and 4) All these substances move through specific membrane sites but it is not known whether insulin stimulates transport by increasing the available number of sites or by increasing the efficiency with which the sites operate

The alkali cation transport system, the Na-K ATPase, is well suited to explore this problem The Na-K ATPase is selectively inhibited by ouabain[5,6] By the use of ^{3}H-ouabain it is possible to determine the extent of the binding of the inhibitor and estimate the number of transport sites, while the alkali cation transport can be assayed by measuring the transport of labelled cations

We have studied the effects of insulin on ^{3}H-ouabain binding and ^{22}Na efflux of frog muscle Paired sartorii dissected from the same frog (*Rana pipiens*) were used to provide control and test muscles The techniques used to measure the efflux of labelled sodium have been described several times[7,8] An apparatus that transfers the muscles automatically from container to container was used[9] ^{3}H-ouabain (New England Nuclear) binding was measured in the following manner after equilibrating the muscles in the labelled solution for 50 min, they were transferred through six containers, 10 min in each, containing ouabain-free Ringer solution at 0° C Insulin-treated muscles were incubated in Ringer with insulin for 1 h before being exposed to a solution containing both insulin and ^{3}H-ouabain Excess fluid was removed and the muscles were weighed in a Mettler H10 balance Then they were digested with NCS and counted in a toluene mixture on a Beckman LS150 liquid scintillation counter Quenching was determined by the External Standard-Channels Ratio method In all experiments the concentration of insulin used was 250 mU ml^{-1}

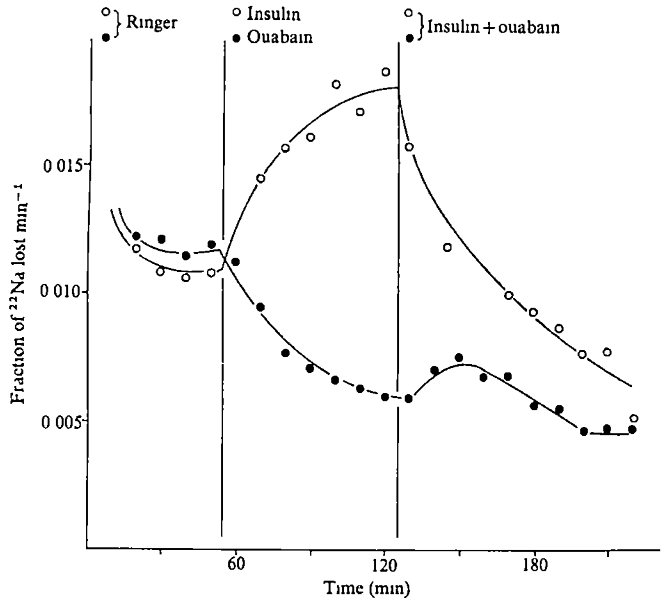

Fig 1 The effects of ouabain on the stimulation of sodium efflux caused by insulin After a control period the control muscle (●) received ouabain (1 × 10^{-6} M) and the test muscle (○) insulin (250 mU ml^{-1}) Then both muscles were transferred to solutions containing both ouabain and insulin

Figure 1 shows the stimulation of sodium efflux caused by insulin and its inhibition by ouabain The inhibitor reduced sodium efflux in the control muscle to a level equal to 0 50 times the resting value This is in agreement with previous observations which show that only about half of the Na efflux in frog muscle is ouabain sensitive, the remaining efflux consists mostly of an exchange diffusion process[7,10,11] The subsequent addition of insulin resulted only in a small and transient increase in sodium efflux In the test muscle insulin increased sodium efflux to 1 86±0 10 times (n = 5) the control level After the addition of ouabain, the efflux dropped to a level similar to that observed in the control muscle

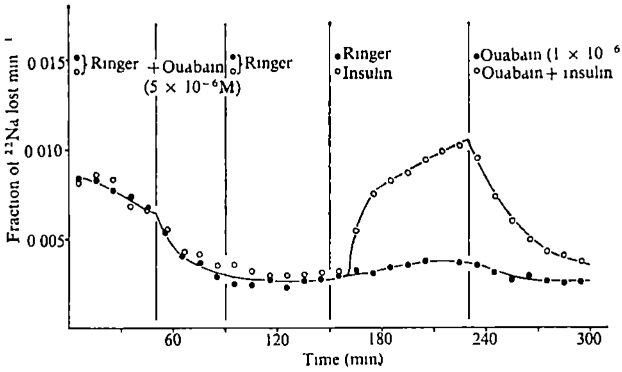

Fig 2 First both muscles were immersed in 5×10^{-6} M ouabain solution, then washed in normal Ringer for 60 min The test muscle (○) was then transferred for 80 min into a solution containing insulin and finally ouabain 1×10^{-6} M was added to the insulin containing solutions The washout of the control muscle (●) was continued in control Ringer until 140 min were completed, then ouabain (1×10^{-6} M) was added

The difference in ouabain binding between paired control muscles was always less than 5% In the experiments on the effects of insulin on ^{3}H-ouabain binding, we used two concentrations of ouabain, 2 5×10^{-7} M and 1×10^{-6} M, which inhibit 40% and 100% of the ouabain sensitive efflux, respectively

Table 1 shows that insulin produced a large increase in ouabain binding The ratios of ouabain binding by insulin treated over control muscles averaged 1 7 The average difference in binding between control and insulin treated muscles was significant for both concentrations of ouabain The scatter in the binding figures arises because there are substantial differences in the amount of ouabain bound by muscles obtained from different frogs

The stimulation of both sodium efflux and ouabain binding strongly suggests that insulin may increase the number of active sodium pumping sites in the muscle membrane To test this possibility further, we performed some experiments based on the observation that the inhibition of the Na-K pump of frog muscle caused by ouabain is very slowly reversible[12,13] Thus one can block all the pumping sites in a resting muscle, then transfer it to an ouabain-free solution and determine whether insulin will still increase sodium pumping Figure 2 shows one out of five experiments performed following this scheme After a control period, the muscles were transferred to solutions containing ouabain (5×10^{-6} M) This concentration abolished the ouabain-sensitive component of sodium efflux The muscles were then washed for 60 min in ouabain-free Ringer solution This treatment does not remove ouabain from specific sites, since there is no recovery of the pump The small increase in sodium efflux observed in Fig 2 after washing the control muscle for 140 min in ouabain-free Ringer is the largest recovery we have observed in these and another series of experiments[12] In the five control muscles of the present series, the ratio of the efflux value measured after washing in ouabain-free Ringer for 140 min over the lowest value measured during the action of ouabain was 1 06±0 05 When insulin was added to the muscle a large increase of sodium

Table 1 Effects of insulin on ^{3}H-ouabain binding

Ouabain concentration	2.5×10^{-7} M	1×10^{-6} M	'Preincubated' 1×10^{-6} M
Control	1661 ± 304	4037 ± 554	1153 ± 325
Insulin	2735 ± 499	6639 ± 825	2700 ± 336
Δ (I-C)	1074 ± 218 $P < 0.01$	2602 ± 683 $P < 0.02$	1546 ± 91 $P < 0.001$
I/C	1.66 ± 0.08	1.71 ± 0.21	3.03 ± 0.66

All binding figures are expressed in d.p.m. per mg/wet weight. Values are averages ± s.e. of the mean ($n = 5$). The specific activity of ouabain was 11.7 Ci mmol^{-1}. Δ(I-C), The difference in binding between insulin-treated and control muscles, P values were calculated using Student's paired t test. I/C, The ratio of the binding of the insulin treated over the control muscles.

efflux was observed. The increase was equal to 0.76±0.10 times ($n = 5$) the resting level. This stimulation of sodium efflux was inhibited when ouabain (1×10^{-6} M) was added to the washout solutions.

Another group of experiments of the same design as those illustrated in Fig. 2 was carried out to measure ouabain binding after saturating the sites available in resting muscle with unlabelled ouabain. They are summarised in Table 1 (preincubated). After immersing both the control muscles and test muscles in 5×10^{-6} M unlabelled ouabain (40 min) they were washed in inhibitor-free Ringer. The test muscles were then equilibrated with insulin and during the final period 1×10^{-6} M ^{3}H-ouabain was added to the solutions. The control muscle also received ^{3}H-ouabain in the final period.

Table 1 shows that preincubation with unlabelled ouabain reduced ^{3}H-ouabain binding in control muscles to about 30% of the value observed in muscles that were exposed directly to ^{3}H-ouabain. The binding remaining after the muscles had received enough ouabain to block all the Na active transport, probably represents binding to sites not linked to the cation transport process, that is unspecific binding. Indeed our own measurements of ^{3}H-ouabain binding by control muscles (to be published in detail elsewhere) show that in muscle cells, as in other cell types[14], ^{3}H-ouabain binding has two components, one associated with inhibition of Na pumping sites and another which represents nonspecific binding. Table 1 also shows that the addition of insulin to muscles preincubated with unlabelled ouabain resulted again in a large and very highly significant ($P < 0.001$) increase in ^{3}H-ouabain binding. The last two columns of Table 1 show that the increase in ^{3}H-ouabain binding caused by insulin was smaller in muscles preincubated in unlabelled ouabain than in muscles that were not preincubated with the unlabelled inhibitor. In principle one would expect that the increase in labelling after insulin treatment should be the same in both experimental groups. We believe that the quantitative disagreement with this expectation is due in great part to the scatter in ouabain binding between muscles obtained from different frogs mentioned previously, since the difference in insulin-induced binding between both groups is not statistically significant ($P > 0.1$).

In any case, the parallel augmentation in ouabain-sensitive Na efflux and ouabain binding in muscles whose resting Na pump sites had been blocked by preincubation in unlabelled ouabain suggests that both phenomena are linked and provide further support for the notion that insulin acts by increasing the number of sodium pumps in the muscle membrane.

It could still be argued that insulin destabilises the ouabain-enzyme complex. The dissociation of the complex would result in the termination of the inhibitory effects of ouabain on the sodium efflux and would make available for binding those sites previously occupied by unlabelled inhibitor. This possibility is ruled out by two observations. First, that ^{3}H-ouabain binding measured without previous exposure to unlabelled ouabain is stimulated by insulin and second, that after equilibrating four pairs of muscles with ^{3}H-ouabain for 50 min, the test muscles were washed for 60 min in solutions containing insulin while the paired control muscles were washed in Ringer solution. Washing with insulin did not decrease the amount of bound ^{3}H-ouabain. The ratio of ^{3}H-ouabain remaining in the insulin-washed muscle over the Ringer-washed muscle was 1.008±0.04 ($n = 4$).

Assuming that one ouabain molecule blocks one pump site, that inhibition of the pump is directly proportional to the number of ouabain molecules bound per cell and a surface weight ratio of 0.415 cm^2 mg^{-1} in frog muscle[8], we arrived at a number of 1,500 pumping sites per square micrometre of membrane of control muscles for both concentrations of ouabain shown in Table 1. The estimates of membrane area consider only the cylindrical surface area of the muscle, since it is possible that pump sites are also present in the transverse tubular system, the number of pump sites per unit area could be overestimated by a constant factor. The calculation involves also the assumptions that 90% of the binding was specific when 2.5×10^{-7} M ouabain was used and 70% was specific for 1×10^{-6} M ouabain. These figures were estimated from our measurements of the kinetics of ouabain binding by control muscles and following criteria developed from observations in HeLa cells[11], since binding of ouabain shares many common features in both types of cells.

The most interesting conclusion of these experiments is that insulin stimulates sodium pumping by increasing the number of pumping sites in frog muscle. This increase in number of pumping sites could result either from unmasking of latent pump sites or from synthesis of new enzyme. We found that the increase in ouabain binding caused by insulin was unaffected by the protein synthesis inhibitor cycloheximide (100 µg ml^{-1}). This observation suggests that the latter possibility is not likely.

We thank Dr J. Aceves for suggestions during the course of this work.

Surface and cell membrane activities of leukocyte chemotactic factors

PROTEINS with an affinity for air–water interfaces may also show an affinity for hydrophobic sites in cell membranes. In exploring the basis for recognition in leukocyte chemotaxis, I and my colleagues have previously reported that proteins which excite a locomotor response in leukocytes do so by virtue of their possession of externally positioned nonpolar groups[1-3]. A protein may possess such groups either because it has become denatured, because nonpolar groups have been conjugated to it, or because, like α_s- or β-caseins, its intrinsic content of nonpolar residues is too high for them all to be packed internally[4]. These proteins would be expected to be surface active and could possibly penetrate the phospholipid bilayer of a leukocyte to activate the cell for chemotaxis in a way that a more hydrophilic protein could not. This paper presents evidence that the surface activity and the chemotactic activity of proteins are indeed related, and that the chemotactic response of the leukocyte can be modified using membrane-active enzymes such as phospholipase A. These findings support the suggestion that chemotactic factors interact with the phospholipid bilayer of the cell membrane.

Human serum albumin (HSA) (Behringwerke, Marburg, Germany) was denatured either by treatment at *p*H 12 overnight at 20° C followed by return to *p*H 7, or by reduction-alkylation with 2-mercaptoethanol (0.1 M) and iodoacetamide (0.02 M). These preparations were dialysed against Gey's solution, *p*H 7.2 for use and the degree of denaturation achieved was measured by difference spectroscopy against native HSA. Butyryl HSA and guanidyl HSA were prepared as described previously[2]. Milk proteins including fractionated samples of

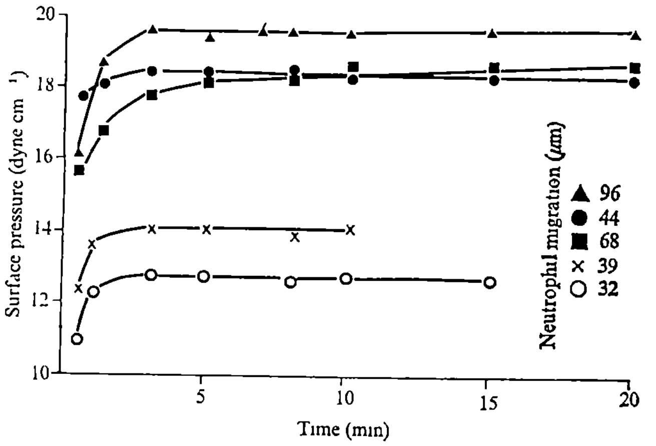

Fig. 1 Surface activity and chemotactic activity for neutrophils of native and modified human serum albumin (1 mg ml^{-1}). Both activities were measured on the same sample of each protein on the same day. The graph shows surface pressure measured against time after formation of the surface. The figures on the right represent the migration of neutrophils through a filter of 3 μm pore size towards each of the proteins, measured as the distance reached by the leading front of cells after 75 min at 37° C. ▲, Alkali-denatured HSA, ■, butyryl HSA, ●, reduced alkylated HSA, ×, guanidyl HSA, ○, HSA

casein were obtained by courtesy of Dr R. L. J. Lyster, National Institute for Research in Dairying, Shinfield, Reading. Unfractionated 'Hammarsten' casein was purchased from Merck A.G., Darmstadt, Germany.

To obtain a direct comparison of the two activities in a physiological medium, surface pressure and chemotactic activity were both measured on the same sample of each protein at 1 mg ml^{-1} in Gey's solution. The surface pressure at the air/Gey's solution interface was calculated from measurements of the force required to pull a glass plate out of the protein solution or Gey's solution at 20° C at timed intervals after pouring. Neutrophil leukocytes were obtained from normal human blood. The chemotactic assay was performed using modified Boyden chambers as described previously[2] and leukocyte migration within the micropore filter was measured by the leading front method of Zigmond and Hirsch[5]. The experimental conditions usually employed in Boyden-type assays do not distinguish directional from nondirectional locomotion of leukocytes. But using the modified assay systems described by Zigmond and Hirsch[5], the proteins studied here have previously been shown[6] to enhance both directional and nondirectional locomotion of leukocytes and may therefore legitimately be described as chemotactic factors.

Figures 1 and 2 show the surface pressures of various protein preparations and the migration of neutrophils towards the same preparations. Procedures which increased the surface activity of HSA (butyrylation, alkali denaturation) yielded products which attracted leukocytes more strongly than those showing smaller changes in surface activity, for example guanidyl-HSA (Fig 1).

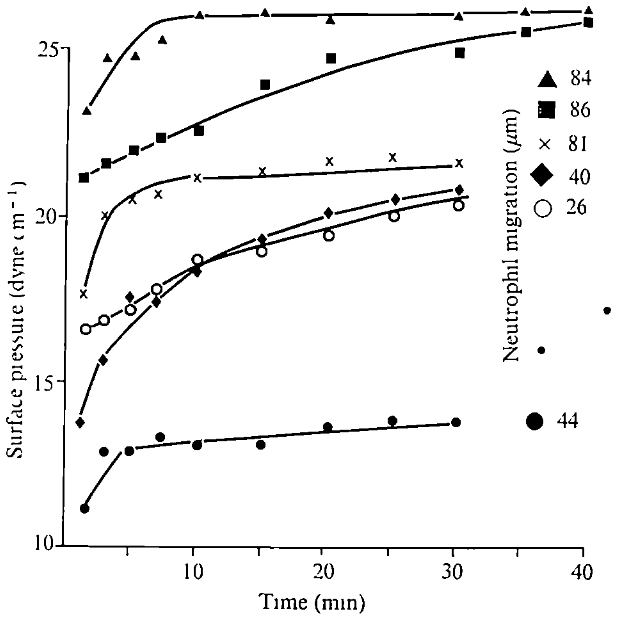

Fig. 2 Surface activity and chemotactic activity for neutrophils of fractionated milk proteins (each protein at 1 mg ml^{-1}). Both activities were measured on the same sample of each protein on the same day. Further details as in the legend to Fig 1. ▲, β-casein, ■, whole casein, ×, α-casein, ◆, α-lactalbumin, ○, k-casein, ●, β-lactoglobulin

The data for milk proteins are shown in Fig 2. Again the proteins (β-casein, α-casein and whole casein) which were most surface active also attracted neutrophils most strongly. Chemotactic substances may therefore be surface active. It is, however, important to note that not all surface active substances are chemotactic. Although the bee venom peptide, melittin, is highly surface active[7], it does not attract leukocytes. Cells incubated with melittin (Sigma, 10^{-5} M to 10^{-6} M) and observed directly showed cytoplasmic movements for a few minutes and

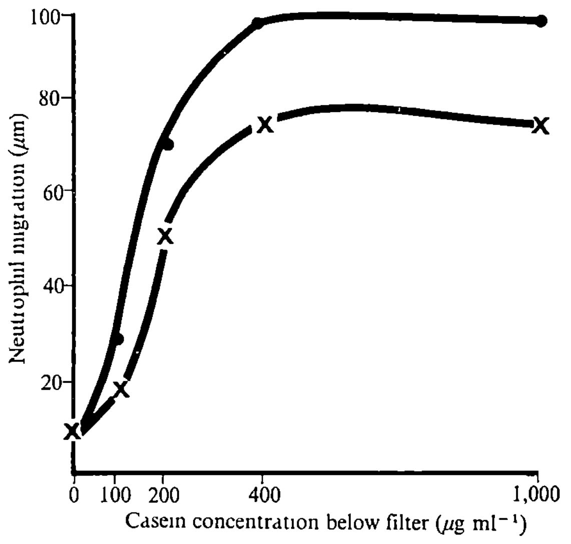

Fig. 3 Effect of phospholipase A on the migration of human neutrophils towards varying concentrations of whole casein. Healthy, freshly taken neutrophils (1×10^6 ml^{-1}) were preincubated for 1 h at 37° C with whole casein (50 μg ml^{-1}) with or without bee venom phospholipase A (50 mU ml^{-1} purified by Dr R. A. Shipolini, Department of Chemistry, University College London[8]). The cells and proteins were then added to the upper compartment of a Boyden chamber. The cells were allowed to migrate for 75 min towards casein at varying concentrations with (●) or without (×) phospholipase A (50 mU ml^{-1}) in the lower compartment. The phospholipase A alone had no effect on leukocyte migration. Provided that the neutrophils had not been spun in Ficoll-triosil, and that they were preincubated with the chemotactic factor as well as phospholipase, the result shown was reproducible.

then flattened out and sometimes lysed At lower, nontoxic, concentrations there was no effect on locomotion Chemotactic proteins probably require to interact with the cell membrane to initiate a locomotor response but without causing sufficient perturbation to damage the cell Furthermore, small surface active molecules such as the nonionic detergent, Tween 80 (Atlas, Wilmington, Delaware) or the anionic detergent sodium dodecyl sulphate showed no chemotactic activity at noncytotoxic concentrations, suggesting that chemotactic factors may require to be macromolecules

The hypothesis that chemotactic proteins interact with the membrane bilayer is supported by preliminary studies of the influence of treatment with membrane active enzymes on the migration of leukocytes towards the substances discussed above Treatment with phospholipase A enhanced the migration of neutrophils towards these substances (Fig 3) This effect was observed using a highly purified enzyme from bee venom[8] as well as with commercial preparations of phospholipase A derived from the venom of Russell viper (Koch-Light) and *Naja naja* (Koch-Light) To interact with the phospholipids of the cell membrane, phospholipase A has been shown to require the presence of direct lytic factor which is not present in pure enzyme preparations But surface active agents[9] and polypeptides with nonpolar groups[10] may replace direct lytic factor and allow the phospholipase to reach its substrate It is possible that chemotactic factors might act in the same way Glycosidases (neuraminidase, β-glucosidase, β-galactosidase) had little effect on leukocyte migration Trypsin at high doses (2 mg ml^{-1}) caused some reduction in migration

These results suggest that the locomotor response of leukocytes to chemotactic factors is initiated by an interaction of the factor within the cell membrane bilayer itself, rather than with superficially placed structures, and that the relatively hydrophobic nature of these factors allows them to penetrate to interact at hydrophobic sites within the bilayer This is supported by the enhancement of their chemotactic activity by phospholipase A which may facilitate entry of the chemotactic factor to the interior of the membrane Interaction with a site deep in the membrane may be an essential preliminary step in initiating intracellular events such as microfilament contraction leading to locomotion Since it has also been suggested that the ability of particles to be phagocytosed by neutrophils and macrophages may be determined by the relative hydrophobicities of the particle and of the cell which is to ingest it[11,12], it is possible that phagocytosis as well as locomotion is initiated by an interaction similar to that proposed here

B cell-derived immunoglobulin on activated mouse T lymphocytes

IT is generally accepted that B lymphocytes express a high density of surface immunoglobulin (Ig) The presence of surface Ig on T lymphocytes, by contrast, is controversial Thus, in mice, T cell surface Ig is considered to be undetectable by some workers[1–3], others, by contrast, report that T lymphocytes express as much surface Ig as B cells[4]

Several groups have shown surface Ig on activated T cells (T-TDL) obtained from thoracic duct lymph of irradiated F_1 hybrid mice injected with parental strain thymus cells[4–6] This communication presents evidence that a proportion of this Ig is of B cell origin

T-TDL were collected from irradiated (800 r) (CBA×C57BL)F_1 hybrid mice injected 4–6 d previously with 2×10^8 CBA or C57BL thymus cells[7] Surface Ig on T-TDL was investigated by indirect immunofluorescence[8] When T-TDL were collected 4–5 d after thymus cell injection, 49% were stained by purified rabbit anti-mouse Ig antibodies (Table 1) The staining was clearly discernible but was less intense than that shown by a small subpopulation (<0 3%) of the cells, the latter have been shown by other criteria to be B cells[9] Most of the Ig detected on T-TDL collected at this stage was IgM Staining with antisera against IgG$_1$, IgG$_{2a}$ and IgG$_{2b}$ was not above the control levels (3%) obtained with normal rabbit IgG With T-TDL collected at 5–6 d, a higher proportion of the cells was Ig-positive (Table 1) and the intensity of staining was increased IgM continued to be the predominant class, although most of the cells also expressed IgG

The great majority of Ig-positive cells in T-TDL were undoubtedly T cells (95% are θ-positive) The surface Ig on on T-TDL could have been synthesised by these cells, alternatively, it might have been derived from B cells, for example, those present in the thymocyte inocula from which the T-TDL were derived To investigate this possibility, T-TDL were prepared from thymocytes depleted of B cells by passage through a Sephadex G-100 column conjugated with rabbit anti-mouse Ig antibody (modified from ref 10) This procedure caused a 12-fold reduction in numbers of strongly Ig-positive (B) cells, that is, from 0 9% to 0 08% No loss of B cells occurred when thymus cells were passed through control columns coated with normal rabbit IgG (NRIgG)

T-TDL derived from thymus cells filtered through a control column showed no changes in Ig staining relative to T-TDL derived from untreated thymocytes (see Tables 1 and 2) There was, however, a marked decrease in Ig-positive cells when the thymus cell precursors of T-TDL were passed through the anti-Ig immunoadsorbent column (Table 2) A higher proportion of T-TDL derived from B cell-depleted thymus were stained after incubation with NRIgG (Tables 2 and 3)

T-TDL depleted of surface Ig were still capable of specific antigen recognition Thus, they were unimpaired in their ability to lyse ^{51}Cr-labelled allogeneic tumour cells during a 6 h incubation period (Table 3) The presence of purified rabbit anti-mouse Ig antibody at a concentration of 1 mg ml^{-1} did not significantly impair lysis (Table 3)

The above experiments clearly suggested that much of the IgM on T-TDL was derived from B cells in the thymus cell inocula used to prepare the cells Direct evidence on the origin of the IgG on T-TDL was obtained with the use of an antiserum directed against allotype *a* of the Ig-1 locus expressed by IgG$_1$ and IgG$_{2a}$ (G F Mitchell and L Herzenberg, personal communication) (see legend to Fig 1)

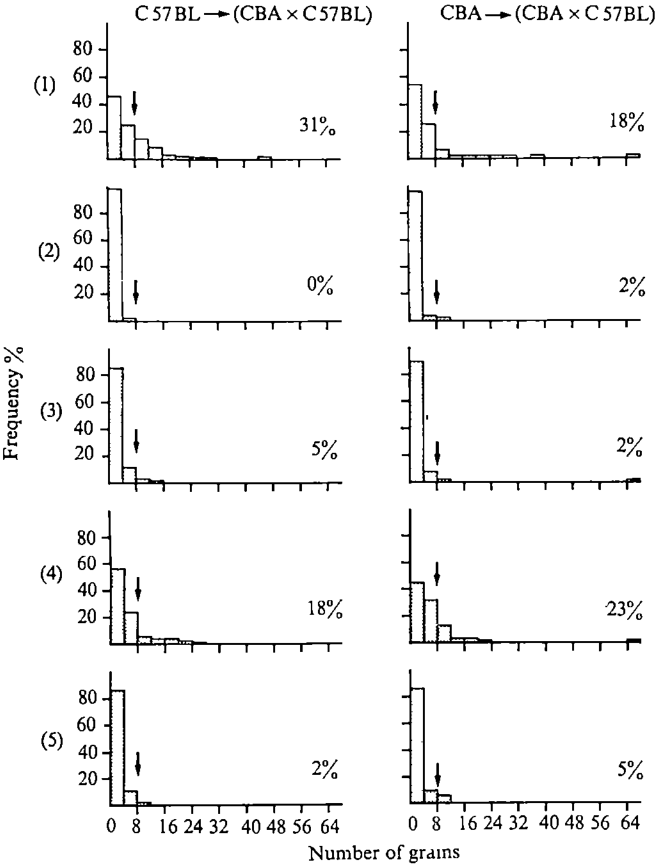

Fig. 1 T-TDL were generated by the transfer of 2×10^8 C57BL or CBA thymocytes in irradiated (800 r) (C57BL×CBA)F$_1$ hybrids T-TDL were collected 5–6 d after transfer Aliquots of 10^7 CBA- or C57BL-derived T-TDL were incubated with one of the following (1) 200 µg of ^{125}iodine-labelled *b* anti-*a* allotype γ-globulin (^{125}I-*b* anti-*a* Ig), (2) uniodinated *b* anti-*a* Ig in a 5-fold excess for 30 min, and then 200 µg of iodinated ^{125}I-*b* anti-*a* Ig, (3) a 5-fold excess of CBA γ-globulin (*a* Ig) in the presence of 200 µg iodinated ^{125}I-*b* anti-*a* Ig, (4) a 5-fold excess of C57BL γ-globulin (*b* Ig) in the presence of 200 µg iodinated ^{125}I-*b* anti-*a* Ig, (5) 200 µg of ^{125}iodine-labelled normal C57BL γ-globulin (^{125}I-*b* Ig) All incubations were at 4° C for 30 min, cells were then freed of unbound γ-globulin by washing through discontinuous gradients of foetal bovine serum, and finally processed for autoradiography After development, grain counts were performed on four coded slides per group, a minimum of 200 cells per group were counted The percentage of cells bearing more than eight grains (indicated ↓) is shown in each group

T-TDL bound this anti-*a* allotype serum irrespective of whether they were derived from CBA (allotype *a*) or C57BL (allotype *b*) thymus (Fig 1) The binding of the labelled antibody was specific since it was blocked by pretreatment with a five-fold excess on non-iodinated antibody and was reduced by the presence of CBA but not C57BL γ-globulin (Fig 1), furthermore, it stained B cells from lymph nodes of CBA mice but not of C57BL mice (data not shown) These studies indicated that, in the case of T-TDL derived from C57BL thymus, part of the IgG detected on the cells was of recipient origin

The demonstration of surface immunoglobulin on T-TDL by indirect immunofluorescence (Table 1) is in accord with the published data of other groups[4–6] It is probable that all T-TDL carry some surface Ig since staining using purified anti-Ig antibodies detected over twice as many Ig-positive blasts as an IgG fraction of the anti- κ serum (Table 1)

The data presented here suggest that the surface IgM, detected by immunofluorescence, was derived from donor B cells in the thymus cell suspensions from which the T-TDL were prepared

The IgM on T cells might be adsorbed by the Fc binding site, this would be consistent with evidence that a high proportion of H2-activated T cells (ATC) from spleen form rosettes with sheep erythrocytes (SRBC) coated with anti-SRBC (an Fc dependent process)[12,13] If this were the sole mechanism, however, it would be paradoxical that T-TDL prepared from B-cell-depleted thymus cells showed decreased surface IgM, that is, one might have expected recipient Ig to replace the missing donor Ig Significantly rosette formation by ATC from spleen was blocked by free IgG but not IgM Thus if IgM is not cytophilic for T blasts, how are we to account for its presence on T-TDL? An intriguing possibility, analogous to that proposed by Crone *et al* [3], is that the donor IgM antibody might be bound not only to an Fc receptor but also by its combining site to soluble alloantigen specifically captured by the endogenous T cell receptor According to this view, donor B cells in the thymus inoculum would produce antibody against the recipient alloantigens, some of the antibody would bind to antigen already captured by the antigen-specific receptors on T-TDL, binding would be stabilised by the attachment of the antibody to the Fc receptor Removal of donor B cells would thus remove the precursors of cells producing such antibody This mechanism might explain the specific qualities of the T-TDL surface IgM isolated by Cone *et al* [14]

The IgG of host origin cannot be accounted for by this

CBA thymocytes were filtered through anti-Ig or NRIgG immunoadsorbent columns 2×10^8 of these cells were transferred to 800 r irradiated (CBA×DBA/2)F$_1$ hybrids T-TDL were collected 5/6 d after thymocyte transfer, and after washing, were mixed with ^{51}Cr-labelled P815Y mastocytoma cells at a ratio of 20 1 and 10 1[11] The cell mixtures were incubated at 37° C for 6 h and the % ^{51}Cr release then counted In addition, 1 mg ml^{-1} of rabbit anti-mouse Ig antibody or NRIgG was added to identical mixtures throughout the incubation period

mechanism since the F$_1$ (recipient) cells presumably cannot recognise the donor (parental) antigens This IgG, but not donor-derived IgG, is therefore probably acquired by Fc receptors It has not yet been possible, however, to obtain direct evidence that Fc receptors are expressed by T-TDL[9]

How can the discrepancy between these findings with ATC-spleen and T-TDL be explained? According to the model considered above, alloantigen bound to endogenous T cell receptors could act as an immunadsorbent to facilitate the capture of specific antibody, the Fc portion of this antibody might preferentially come to occupy the Fc receptors on the cell, thus saturating these receptors and preventing nonspecific uptake of extraneous Ig It is possible that the splenic architecture may allow T blasts (ATC) to be formed in an environment relatively free of alloantibody, for example in the T-dependent areas ATC collected from the spleen would therefore have free Fc receptors Subsequent migration of these cells through alloantibody producing areas, for example B-dependent areas, before their eventual appearance in the lymph, would saturate the Fc receptors with alloantibody It would follow, therefore, that Fc receptor blockade would be less evident on T-TDL derived from B cell-depleted thymus cells Though this prediction has yet to be verified, it is consistent with the finding that, unlike normal T-TDL, a high proportion of T-TDL derived from B cell-depleted thymocytes bound NRIgG (Tables 2 and 3)

The mechanism proposed for specific antigen and antibody capture by activated T cells can be invoked to explain two phenomena observed by other workers

(1) T rosette-forming cells (T-RFC) to SRBC from mice can, unlike most other T-cell reactions, be blocked by anti-light chain and anti-IgM sera It is suggested that such immune rosettes are formed by specifically activated T cells binding a complex of antigen and specific IgM antibody, the Fc of the immunoglobulin stabilising the binding of antigen and the free combining sites of the antibody being available to bind the RBC used to form rosettes[15]

(2) Bursectomised chickens are deficient in cells forming specific rosettes with SRBC But preinjection of these birds with an anti-SRBC serum restores the numbers of RFC to the levels found in normal chickens[16] It is possible that the antiserum used here contained antigen–antibody complexes in antibody excess If so, then according to the model considered above, the complexes would bind only to specific T cells the antigen attaching to the endogenous receptors of the cells and being held there by Fc binding of the antibody The free binding sites of the antibody would be available to form rosettes

The possible role of this mechanism in initiating or aiding cellular cooperation *in vivo* has been recently reviewed by Playfair[17]

Despite the evidence presented here and in other studies[18,19] that much of the surface Ig on T cells is of exogenous origin, the proposed mechanism for stabilising antigen-binding by T cells requires that these cells express antigen-specific receptors These may or may not be immunoglobulin But it is clear that in all experiments attempting to demonstrate endogenous synthesis of immunoglobulin by T cells, one must consider the possible presence of B cell-derived immunoglobulin

We thank Miss Nazra Thantrey and Miss Patricia Young for technical assistance, and Miss Penny Hamilton for preparing the manuscript Drs G F Mitchell and L Herzenberg kindly provided the anti-allotype serum L H was supported by grants from the Medical Research Council of Great Britain J F A P M was supported by grants from the National Health and Medical Research Council of Australia, the Australian Research Grants Committee, the Damon Runyon Memorial Fund for Cancer Research and the Australian Kidney Fund

Note added in proof As a corollary to the above model, if activated T cells are generated in situations where alloantibody is not produced, as for example between mice differing only at the M locus, immunoglobulin should not be demonstrable on the surface of the activated cells This has been shown experimentally to be the case (Hudson, L, Sprent, J and von Boehmer, H, unpublished data)

Removal of specific cooperative T cell factor by anti-H-2 but not by anti-Ig sera

ANTIBODY production to thymus-dependent antigens requires cooperation between thymus derived (T) and bone marrow derived (B) lymphocytes[1] B cells are the precursors of the antibody producing cells, but they apparently require the stimulatory influence of T cells in order to be triggered to proliferate and differentiate into plasma cells The nature of the cooperative stimulus which passes from T cell to B cell is not yet established, though several possibilities have been discussed[1–3] There is evidence that T cells produce various mediators which may stimulate B cells, including nonspecific as well as antigen-specific T cell products

One of us has recently described the production of an antigen-specific factor by specifically activated or 'educated' mouse T cells[4] The factor is capable of replacing T cells in a cooperation dependent antibody response *in vivo* We have attempted to identify this T cell product by removing it with various antisera immobilised as immunoadsorbents The results described here show that the factor could not be removed by a sheep anti-mouse immunoglobulin (Ig) adsorbent, but was removed completely by congenically raised anti-H-2 antibodies

The production and activity of the specific cooperative T cell factor have been described in detail in a previous report[4] The antigen used was the multichain synthetic polypeptide poly(Tyr, Glu)-polyDLAla—polyLys, abbreviated as (T,G)-A—L (ref 5), supplied by Dr Edna Mozes (Department of Chemical Immonology, The Weizmann Institute of Science, Rehovot, Israel) Mice used were of the strains BALB/c, C57BL/10ScSn (B10) and strains congenic with B10, namely B10 D2, B10 Br and B10 A All strains were obtained from the Laboratory Animal Centre, Carshalton, and were bred at the Department of Pathology, Tennis Court Road, Cambridge In brief, T cells, primed or educated to (T,G)-A—L *in vivo*, were incubated together with antigen *in vitro* for 6–8 h The cells were then removed by centrifugation and the supernatant, containing the T cell factor, transferred together with bone marrow cells and (T,G)-A—L into lethally irradiated, syngeneic recipients After 14 d the direct plaque forming cell (PFC) response to (T,G)-A—L in the spleens of the recipients was measured and compared with controls receiving B cells and antigen but no factor, or B cells with T cells and antigen

Table 1 Inability to remove T cell factor by anti-mouse Ig adsorbent

Direct anti-(T, G)-A—L PFC responses in irradiated (750 r) BALB/c mice 14 d after receiving combinations of syngeneic B cells, T cells and T cell factor, adsorbed as indicated

Antisera used for absorption of the factor were raised as follows Sheep anti-mouse Fab′ was prepared by immunisation with the Fab′ fragment of BALB/c myeloma protein AdjPc5 (the myeloma was originally provided by Dr Michael Potter) First inoculation was given in Freund's complete adjuvant, followed by several inoculations in solution The alloantisera used were anti-H-2^d, anti-H-2^k and anti-H-2^b and were raised in strains congenic with those producing the factor under test Anti–H-2^d was prepared by repeated weekly inoculation of DBA/2 spleen cells into B10 Br (H–2^k) mice, anti-H-2^k was prepared by repeated weekly inoculation of CBA spleen cells into B10 D2 (H-2^d) mice, and anti-H-2^b by repeated weekly inoculation of either C3H WB or B10 spleen cells into B10 A (H-2^a) mice All the sera were cytotoxic, in the presence of complement, for lymphocytes of the appropriate H-2 type, with the exception of one of the anti-H-2^b sera (B10 cells into B10 Br) Immunoadsorbents were prepared from these sera, as well as from normal mouse serum, by precipitating the gamma globulin with 45% $(NH_4)_2SO_4$ and coupling to activated sepharose after removal of the $(NH_4)_2SO_4$[6] T cell factor was tested immediately after preparation by passage over the immunoadsorbents in the form of short columns, and was then mixed with B cells and (T,G)-A—L and transferred into irradiated recipients as above

¶ Produced by one spleen equivalent educated T cells

Direct anti-(T, G)-A—L PFC responses in irradiated (850 r) B10 D2 (H-2^d) mice 14 d after receiving combinations of syngeneic B cells, T cells and T cell factor The factor, produced by B10 D2 T cells, was adsorbed as shown

The first results show an attempt to remove the T cell factor by passage over a sheep anti-mouse Fab′ column (Table 1) The factor, which was in this case prepared from BALB/c T cells educated to (T,G)-A—L, emerged from such a column with undiminished ability to cooperate with B cells in the response to (T,G)-A—L *in vivo* The ability of the anti-Fab′ column to bind mouse Ig was established using radiolabelled mouse Ig The conclusion may be drawn from this experiment that the nature of the cooperative T cell factor is not that of conventional mouse Ig, at least in so far as it does not seem to carry mouse κ chains, the predominant light chain type of mouse Ig But since the sheep serum was raised against a mouse myeloma Fab′, various other possibilities still remain open, though they are rather unlikely, for example the T cell factor carries λ rather than κ chains, or is composed of heavy chains without light chains With these reservations, and within the limitation that only one anti-mouse Ig serum has been used in this work so far, the result shown in Table 1 strongly suggests that T cell factor is not Ig This finding also rules out any remaining suspicion that the T cell factor may be a B cell contaminant

Attempts were then made to remove the T cell factor, with immunoadsorbents prepared from alloantisera Congenic strains derived from the B10 genotype and differing only in the major histocompatibility locus, H–2, were used Table 2 shows the results of an experiment in which T cell factor was prepared in the B10 D2 strain (H–2^d) and passed through immunoadsorbents of either anti-H-2^d or anti-H-2^k specificity, or normal mouse globulin The factor was totally removed by the anti–H–2^d adsorbent, but not at all by anti–H–2^k or normal mouse globulin Since the anti-H-2^d serum was prepared in a congenic strain (by injection of DBA/2 spleen cells into B10 Br mice), it is very unlikely to have reacted with any B10 D2 antigens other than those in the H-2 complex The result thus implies that the T cell factor carries alloantigenic determinants of the T cells from which it is produced This finding was confirmed in another strain, B10 (H–2^b) (Table 3) T cell factor was prepared from B10 T cells educated to (T,G)-A—L, and passed through adsorbents containing anti-H-2^{b} or anti-H-2^{d} Two anti-H-2^{b} adsorbents were employed, both prepared from alloantisera raised in the congenic B10 A (H-2^{a}) strain, one by inoculation of C3H WB spleen cells and the other by inoculation of B10 spleen cells themselves Both these adsorbents completely removed the T cell factor produced by B10 educated T cells In contrast, the anti-H-2^{d} adsorbent which successfully removed the factor produced by B10 D2 T cells did not adsorb that produced by B10 T cells (Table 3) It may be noted that the latter result rules out the possibility that the anti-H-2 sera adsorb the factor because they contain antibodies cross-reacting with (T,G)-A—L itself, to which the factor may be bound[7] An anti-(T,G)-A—L adsorbent itself also fails to remove the factor (personal observation)

These results strongly suggest that the cooperative T cell factor is physically associated with alloantigens of the strain in which it is produced The interpretation of these findings clearly depends on the specificities of the antibodies present in the alloantisera used The alloantigens coded for by the H-2 region and expressed on the T lymphocyte surface include the products of the H-2K and H-2D regions, and in addition probably the products of the H-2-linked immune response (Ir) genes[8] The latter control the levels of immune responses to specific antigens and in the mouse have been mapped in a region within the H-2 locus, between the H-2K and H-2D 'ends' and closer to H-2K[8] There is evidence that Ir genes are functionally expressed in both T[8,9] and B cells (refs 10-12 and G M Shearer, pages 38-39 in ref 8) The finding that antisera to the H-2 complex remove the T cell factor may imply either that the factor is identical with the product of the H-2K or H-2D genes, or that it is an *Ir* gene product, or possibly that it is some as yet unidentified molecule which becomes physically attached to one of the H-2 products Perhaps the most attractive speculation is that the factor consists of both the Ir and H-2K or H-2D gene products physically combined The products of H-2K or H-2D might provide the 'constant' region of a molecule analogous to immunoglobulin, with Ir gene products providing the variation required for specific antigen binding The use of recombinant strains, providing different combinations of H-2K, Ir and H-2D, should resolve this problem

What is the relationship between T cell factor and T cell receptor? The most important feature of the T cell factor is its specificity for the inducing antigen[4] By analogy with B cells, it is highly unlikely that T cells would produce a specific molecule that was different, in terms of antigen recognition, from the T cell receptor It seems most probable, therefore, that the T cell factor is the soluble expression of the T cell receptor, that is, that the T cell factor and the T cell receptor are closely related molecules The conclusion that the T cell receptor is intimately associated with H-2 region products finds considerable support in the work of others Attempts to demonstrate Ig on the T cell surface have been largely unsuccessful (refs 13, 14, E Unanue, pages 207-220 in ref 8, and J W Uhr, pages 228-238 in ref 8), despite some positive reports[15-18] Anti-Ig serum fails to inhibit T cell functions such as mixed lymphocyte reaction (MLR) (I Roitt, quoted in ref 1, page 118) and graft-*versus*-host (G*v*H) reaction[19], though antigen binding by T cells, helper activity and 'hot' antigen T cell 'suicide' have all been successfully inhibited by such sera[20-22], and a 7S IgM derived from activated T cells is able to cooperate with B cells *in vitro*[3] The likelihood that T cells adsorb antibody on to their surface[23] makes interpretation of the positive results difficult against the background of widespread failure to show conclusively that Ig is the primary T cell receptor The failure, reported here, to remove the T cell factor on an anti-Ig adsorbent also strongly suggests that the factor, and by inference the T cell receptor, are non-Ig in nature On the other hand, positive association between T cell receptor and histocompatibility (H) antigens includes the blocking of MLR and PPD proliferative responses of human lymphocytes by anti-HL-A sera *in vitro*[24,25], the inhibition of the G*v*H response by alloantibodies[19], and the abolition of the response of guinea pig T cells to specific antigens *in vitro* by antisera against H antigens[26] This last observation is clearly analogous to the absorption of T cell factor by alloantibodies, and it is interesting to note that in the guinea pig the active antibodies are apparently directed at H rather than Ir gene products[27] The authors, in this latter case, also conclude that H and Ir gene products must be linked physically

A summary of our conclusions from the observations described here is as follows H-2 region genes expressed by T cells are very probably responsible for antigen recognition by T cells After recognising antigen, T cells release a soluble, antigen-specific factor which, in conjunction with antigen, is apparently able to transmit a stimulatory signal to B cells The factor consists either wholly or partly of H-2 region gene products This further suggests that the latter are important in the interaction with the B cell and (or) perhaps the macrophage

Isolation of a purified preparation of metabolically active retinal blood vessels

THE retinal vascular system has long been of interest to both clinicians and basic scientists because of its involvement in a number of systemic diseases, particularly hypertension and diabetes mellitus, and its accessibility to *in vivo* study through direct observation due to the transparency of the eye. This accessibility has made it an ideal system for the study of a portion of the microcirculation in various physiological and pathological states as well as under the influence of pharmacological agents. Such studies have advanced considerably the clinical and experimental investigation of retinal vascular disease which is one of the most common causes of visual disturbance and blindness in man. But *in vitro* study of retinal blood vessels has been restricted largely to the examination of retinal digest preparations obtained with the use of proteolytic enzymes[1] or by autolysis of the retina in water[2], and of isolated vessels obtained by microdissection techniques[3]. Metabolic studies on such preparations of isolated vessels have been extremely limited[3] because of the non-physiological conditions used or their tedious and time consuming nature. Therefore, we have developed a simple procedure for the isolation of a purified preparation of bovine retinal vessels which are metabolically active.

Retinal vessels were obtained from freshly enucleated bovine eyes obtained at a local slaughter house. Immediately after removal from the animal, the eyes were bisected and the retinae removed and placed in ice-cold buffer consisting of Earle's balanced salt solution (116 mM NaCl, 16 mM KCl, 1 mM $NaH_2PO_4 \cdot H_2O$, 0.8 mM $MgSO_4 \cdot 7H_2O$, 5.6 mM glucose, 1.8 mM $CaCl_2$) buffered with 28 mM HEPES (N-2-hydroxyethylpiperazine-N-2-ethane sulphonic acid (*p*H 7.4) and containing 0.01% bovine serum albumin, and 50 mg of penicillin G and streptomycin sulphate l^{-1}. The isolated retinae in buffer were carried back to the laboratory on ice where they were minced well with scissors and homogenised with 10 up and down strokes of a hand-held tapered Teflon pestle in a smooth glass tube. One part of tissue was homogenised in four parts of buffer (v/v). The homogenate was then poured over an 86 μm nylon sieve (Kressilk Products Inc., Monterey Park, California) and the sieve washed extensively with buffer. The material remaining on the sieve was washed off into a homogenisation tube and rehomogenised with five up and down strokes of the pestle. The resulting homogenate was again sieved through the nylon sieve and the sieve washed thoroughly with buffer. The material now on the sieve consisted of a purified preparation of retinal blood vessels which were almost devoid of non-vascular tissue contamination with the exception of trapped blood elements, as determined by phase contrast and electron microscopy as well as by light microscopic observations of fixed tissue sections. The yield of vessels from the retinae of 18 cow eyes was 281 mg of wet weight tissue. If preparations enriched in large or small diameter vessels were desired, these could be obtained by first sieving the rehomogenised material through a 210 μm nylon sieve followed by sieving of the filtrate on an 86 μm sieve. The material found on the 210 μm sieve contained vessels of large and medium diameter with attached and adhering vessels of smaller diameter whereas that on the 86 μm sieve consisted almost entirely of vessels of smaller diameter. These preparations were washed off the sieves into centrifuge tubes and sedimented at 1,085*g* for 2 min to obtain a pellet of vessels which were resuspended in a suitable volume of buffer for metabolic experiments.

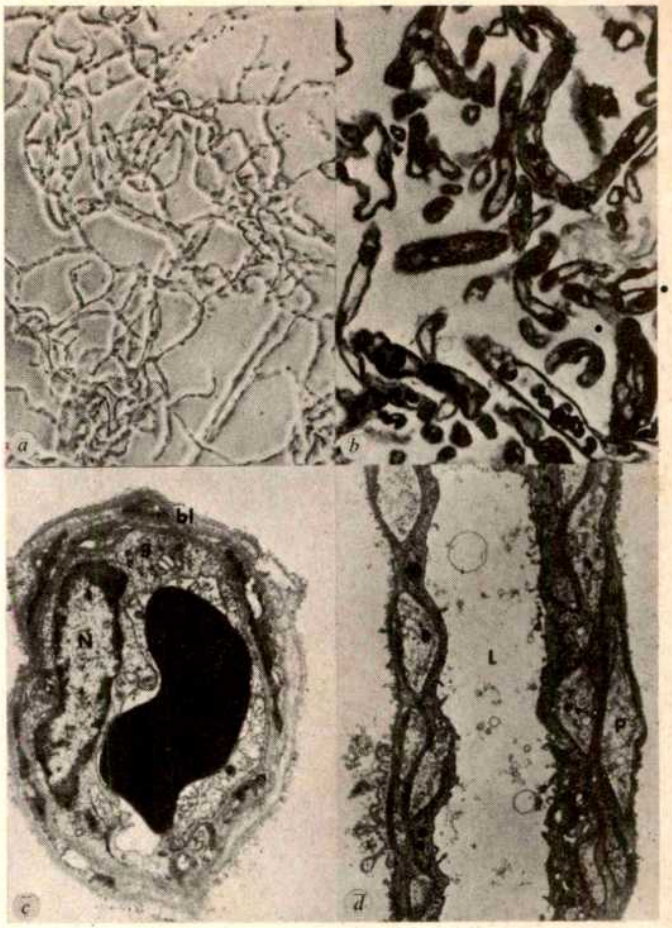

Fig. 1 *a*, Phase contrast photomicrograph of isolated bovine retinal vessel aggregate. Red blood cells are visible within vessel lumina. ×158. *b*, Photomicrograph of epoxy-embedded isolated bovine retinal vessel aggregate. Vessels are cut in various planes of section. Non-vascular surrounding tissues are virtually absent. Toluidine blue, ×470. *c*, Electron micrograph of cross section through isolated retinal vessel. A red blood cell occupies nearly the entire lumen. Endothelium is lined by basement lamina (bl) which surrounds cytoplasmic processes of adjacent pericytes. The endothelial cell exhibits a prominent nucleus (N) and Golgi apparatus (g). ×5447. *d*, Electron micrograph of longitudinal section through isolated retinal vessel. The lumen (L) of the vessel is devoid of cells. A thin endothelium (E) lines this vessel and is surrounded by basement lamina (bl) which varies greatly in thickness and also surrounds intramural pericytes (P) ×3062.

The metabolic activity of the vessel preparations was determined by incubating 0.5 ml aliquots of a suspension of vessels with shaking at 37° C in an atmosphere of oxygen in the presence of appropriate ^{14}C-labelled substrate in a $^{14}CO_2$ collection apparatus described elsewhere[4]. Radioactivity determinations were performed in a Beckman model LS-250 scintillation counter using a scintillation fluid containing one third Triton X-100 (ref. 5). Protein was determined by the method of Lowry[6]. ^{14}C-1-oleic acid (specific activity 9.1 mCi mmol^{-1}) and ^{14}C-2, 3-succinic acid (specific activity 18.3 mCi mmol^{-1}) were products of New England Nuclear Corporation (Boston, Mass.). ^{14}C-6-D-glucose (specific activity 10 mCi mmol^{-1}) was obtained from Calbiochem (Los Angeles, California).

Phase contrast microscopy was carried out on freshly isolated vessel preparations using a Zeiss RA or Ultraphot II microscope. For other microscopic examination isolated blood vessels were fixed for 1 h in cold Karnovsky's[7] fixative, buffered at *p*H 7.3. Postfixation was carried out in 2% OsO_4 buffered with 0.144 M sodium cacodylate. Tissues were dehydrated in a graded series of ethanols and propylene oxide followed by embedment in Epon-Araldite[8]. Thick (1 μm) and thin sections were cut with glass or diamond knives on a Porter-Blum-MT-2 Ultramicrotome. Thick sections were stained with toluidine blue for purposes of orientation and determination of vessel position. Thin sections were stained with uranyl acetate (5% in absolute ethanol) and lead citrate[9]. Light microscopic observations were made on a Zeiss Ultraphot II. Thin sections were observed with a Philips EM-300 electron microscope at original magnifications of 1,200–13,000.

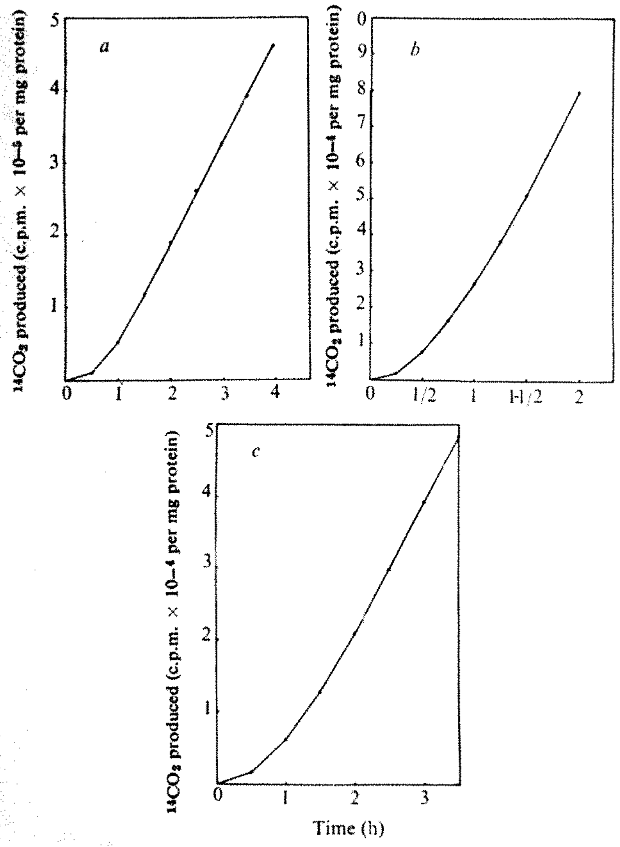

Fig. 2 Oxidative metabolism of several substrates by isolated retinal vessels: *a*, ^{14}C-6-D-glucose (0.25 μCi); *b*, ^{14}C-2,3-succinic acid (0.2 μCi); *c*, ^{14}C-1-oleic acid (0.2 μCi). Each incubation flask contained 83.5–236 μg of retinal vessel protein plus the designated amount of ^{14}C-labelled substrate in 0.51 ml of incubation buffer (minus glucose). Control experiments not shown in Fig. 2 include incubations with buffer alone and with bovine blood dilutions equivalent to blood elements entrapped in the corresponding vessel preparations (300→3,000 red blood cells). These controls yielded no significant $^{14}CO_2$ production over background from identical amounts of the above radioactive substrates.

The technique which we describe for the isolation of retinal blood vessels results in a loose pellet of tissue which to the naked eye appears as a twisted aggregation of very fine thread-like tubules. By phase contrast microscopy (Fig. 1*a*) the pellet can be shown to be composed of an extraordinarily clean preparation of isolated blood vessels. Although the vessels exhibit a wide range of diameters (7–50 μm), most of them are approximately 10 μm in diameter. A few red blood cells are seen free in the dispersion medium, but the remaining tissues are composed of clearly recognisable vessels with enclosed blood elements. The remarkable homogeneity of these tissues is more clearly demonstrated by conventional light microscopy (Fig. 1*b*). Sections 1 μm thick of fixed tissue reveal an aggregate of vessels cut in longitudinal, cross and oblique section. Measurements of these vessels compare favourably with those seen in phase microscopy.

Electron microscopic observations of isolated retinal vessels show an extremely clean preparation. Nonvascular tissues consist largely of blood cells, some of which are found free in the embedding medium. Cross sections of capillaries (Fig. 1*c*) exhibit red blood cells within their lumina. The vessel wall is composed of endothelial cells and a basement lamina which may split to enclose cytoplasmic extensions of smooth muscle cells or intramural pericytes. Endothelial cell nuclei are surrounded by a smooth contoured nuclear envelope interrupted by nuclear pores. Many acanthasomes and micropinocytotic vessels are seen in the peripheral cytoplasm, and a prominent Golgi zone is frequently noted in the perinuclear area. Endothelial flaps adjacent to cellular junctions are frequent modifications of the luminal plasmalemma. In longitudinal section (Fig. 1*d*) the morphological integrity of the endothelium is preserved. Numerous mitochondria lie within the endothelial cell cytoplasm.

The maintenance of the subcellular compartmentation of the vascular cells of preparations isolated using this procedure was supported by their ability to metabolise ^{14}C-labelled oleic and succinic acids and ^{14}C-glucose to $^{14}CO_2$ (Fig. 2), metabolic transformations which cannot be carried out by red blood cells. This was confirmed by control experiments run under identical conditions with amounts of blood elements equivalent to those found entrapped in the incubations with vessels. In the experiment with vessels after an initial lag period, the oxidation of the above substrates was maintained at linear rates and continued at these rates for several hours demonstrating the integrity of the Embden-Myerhof pathway, the pathway of fatty acid oxidation and the Krebs cycle in this preparation. Thus, morphologically and metabolically, this is an intact purified preparation of isolated small blood vessels obtainable in good yield and suitable for analytical, biochemical and pharmacological studies. The isolation procedure avoids the difficulties involved in previously described procedures for the isolation of retinal vessels involving trypsinisation, autolysis of the retina in water and microdissection. Most retinal vessel preparations isolated using these techniques have been used for morphological[1,2] and analytical[10,11] studies and almost nothing is known concerning their metabolism. Metabolic studies have been limited to histochemical investigations[12] and experiments using the Cartesian diver[3]. Investigations of the metabolism of small blood vessels from nonretinal tissues have also been limited to studies of preparations obtained by dissection. Such preparations can be derived readily in adequate amounts only from nonmammalian sources such as the swim bladder of the eel[13]. The availability of a procedure which enables the quick and simple isolation of a purified preparation of small blood vessels in good yield from mammalian retinas should permit further investigations of the properties of this important type of vascular tissue This procedure has also been modified for the isolation of blood vessels from bovine cerebral cortex[14] and may be adapted to the isolation of small blood vessels from other tissues

We thank Dr Franz Matschinsky for helpful suggestions, Mary Lou Rankin and Rosalyn Upson for technical assistance, and R C Jones of Jones Meat Packers who generously provided the bovine eyes used in this study and Harlan Woodruff, Arizona State Meat Inspector

Stimulation of ribosome synthesis during retarded ageing of human fibroblasts by hydrocortisone

CORTISONE[1] and hydrocortisone[2] can prolong the lifespan of human embryonic fibroblasts cultivated *in vitro* and this prolongation is accompanied by a significant increase in the saturation density The same effect has been observed in cultures of primary human amnion cells[3] One of the constant features during senescence *in vitro* of cells from different species is the progressive decrease of the cell density at which growth practically stops, and it has been suggested[4] that the two phenomena, ageing *in vitro* and decrease of the saturation density, are related

It is now well established that ribosome synthesis declines when division slows down during cell crowding[5–10] It has also been reported that RNA synthesis declines during cell senescence[11] Since it has been shown that hydrocortisone stimulates RNA synthesis[12–14] the increased saturation density and lifespan of cells carried in the presence of hydrocortisone could be due to a sustaining effect of the hormone on ribosome synthesis We show here that, in fact, human fibroblasts carried in hydrocortisone-supplemented medium incorporate more radioactive precursors into ribosomes and polyribosomes than the control cultures This effect may be correlated with the retarded ageing induced by the hormone *in vitro*

A human embryonic fibroblastic line was cultured with and without hydrocortisone The controls died at the 44th passage and the hydrocortisone treated cells at the 62nd passage At the 49th passage, cells carried in the hormone supplemented medium were subcultivated in medium without the hormone and died two passages later

At the 36th passage part of the cultures from each group were pooled, subcultivated and counted each day until the growth curves reached a plateau In addition, each day after subcultivation, cells from identical cultures were labelled and collected, and the cytoplasm extracts layered on 7–52% sucrose gradients (Fig 1) According to previous data[15] fractions 10–15 correspond to polyribosomes and fractions 16–25 to single ribosomes Significantly more ribosomes and polyribosomes were synthesised on day 1 and day 2 in hydrocortisone-treated cells During the third day, when the cultures exposed to hydrocortisone had already reached a plateau though the controls were still dividing, the radioactivity incorporated in the polyribosomal fractions was more or less identical in both groups (Fig 1) On day 4 the cultures in both groups had reached a plateau and as expected, very few polyribosomes were synthesised and the radioactivity incorporated in the ribo-

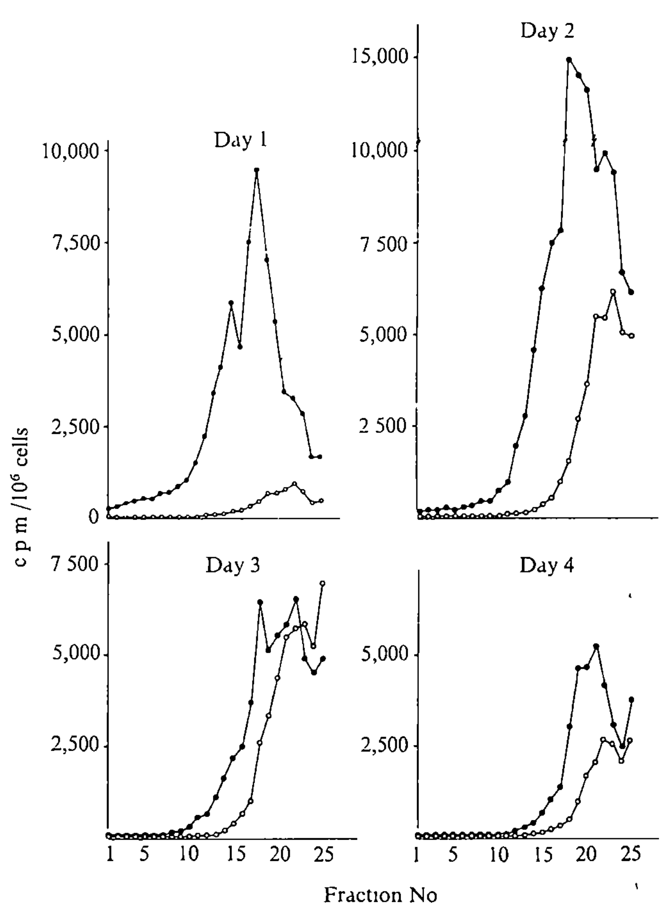

Fig 1 Incorporation of ^{3}H-uridine in ribosomes and polyribosomes each day after the 36th subcultivation of human fibroblasts carried with (●——●) and without (○——○) hydrocortisone Cultures were labelled with 5 μCi ml^{-1} ^{3}H-uridine (specific activity 10 Ci mmol^{-1}) for 3 h The cells were then scraped with a rubber policeman, washed twice in *p*H 8 6 buffer (0 01 M Tris, 0 14 M NaCl, 0 01 M MgCl$_2$) and treated for 10 min in the cold with 0 5% NP^{40} in buffer The cell suspensions were further treated with a Dounce homogeniser and examined under a microscope to see if nuclei were well separated from the cytoplasmas The cell suspensions were centrifuged at 20,000*g* for 15 min and the supernatants were layered on a 7–52% sucrose gradient which was centrifuged at 25,000 r p m for 3 5 h at 4° C in a SW 27 rotor The gradients were collected in 25 fractions and to each fraction 10% TCA was added The fractions were filtered through millipore filters which were digested in Instagel and the radioactivity counted in a liquid scintillation spectrometer The bottom of the gradient is on the left side of the abscissa

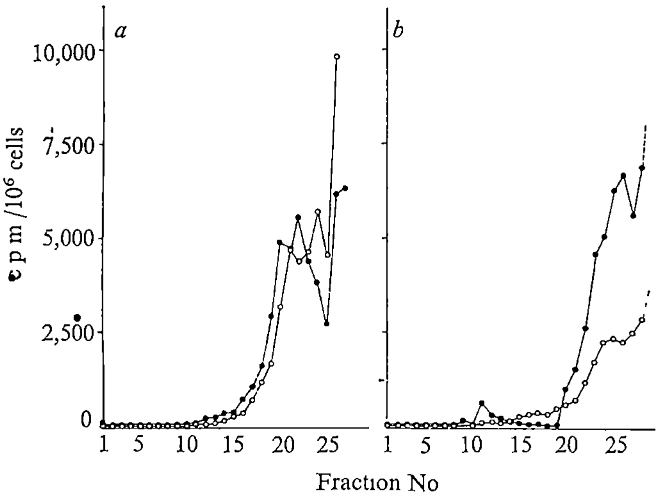

Fig 2 Incorporation of ^{3}H-uridine into ribosomes during *a*, the first and *b*, the second passage after withdrawal of the hormone (O——O) in cells that were cultured with hydrocortisone (●——●) beyond the lifespan of the controls Cells were labelled at the stationary phase and treated as described in Fig 1 The bottom of the gradient is on the left side of the abscissa

somal fraction had declined significantly in both groups Ribosomal synthesis, however, was higher in the hydrocortisone-treated cells No difference between the groups could be detected in the acid-soluble fractions, suggesting that the increased incorporation of uridine is not due to an increased penetration of the precursor into the cell

Since cells cultured in hydrocortisone beyond the lifespan of the controls died within two pasages when cultured in medium without the hormone, we decided to measure ^{3}H-uridine incorporation under these circumstances Figure 2 shows that there was no difference in the incorporation of ^{3}H-uridine into ribosomes from both groups during the first passage after withdrawal of the hormone A significant decrease, however, was found in the ribosomes synthesised after the second passage without the hormone To be sure that this peak corresponds to ribosomes, we separated the ribosomal subunits on a 5–20% sucrose gradient (Fig 3*a*) and then layered on a 7–52% sucrose gradient (Fig 3*b*) identical to the ones described in Fig 1 All subunits were found around fraction 20

Protein synthesis was also measured in hydrocortisone-treated cells and in the controls At the 36th passage cultures from each group were pooled and subcultivated separately Each day thereafter the cells were counted and labelled for 15 min with ^{14}C-labelled amino acids until the growth curves reached a plateau Acid-soluble and insoluble radioactivity were measured A significantly increased protein synthesis (Fig 4) was found on the first day after subcultivation in the cells carried in hydrocortisone supplemented medium When protein synthesis declined (due to cells reaching stationary phase) no difference could be seen in the two groups

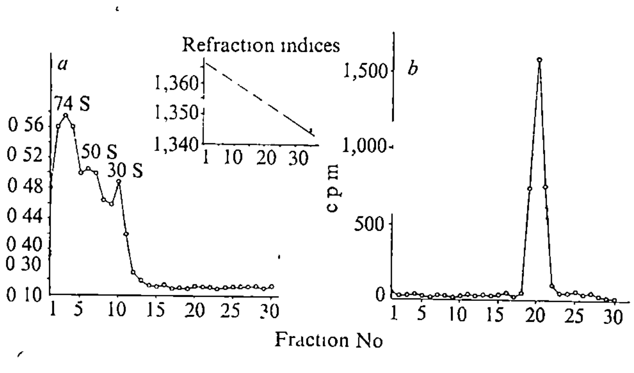

Fig 3 *a*, Separation of ribosomal subunits on a 5–20% sucrose gradient in control human fibroblasts Cells were labelled and the cytoplasmic fraction was prepared as described in Fig 1 and then treated with 0 2% sodium deoxycolate in buffer at 4° C for 30 min The suspension was then centrifuged for 2 h at 105,000*g* in a Beckman 40 rotor The precipitate was resuspended in 1 ml *p*H 7 45 buffer (0 0011 M Na phosphate, 0 0004 M $MgCl_2$) and layered on a 5–20% sucrose gradient which was centrifuged for 2 5 h at 25,000 r p m in a SW 27 rotor The absorbance of the fractions collected from the gradient was measured at 260 nm *b*, The fractions corresponding to the ribosome subunits were layered on a 7–52% sucrose gradient and the radioactivity was measured as described in Fig 1 The bottom of the gradient is on the left side of the abscissa.

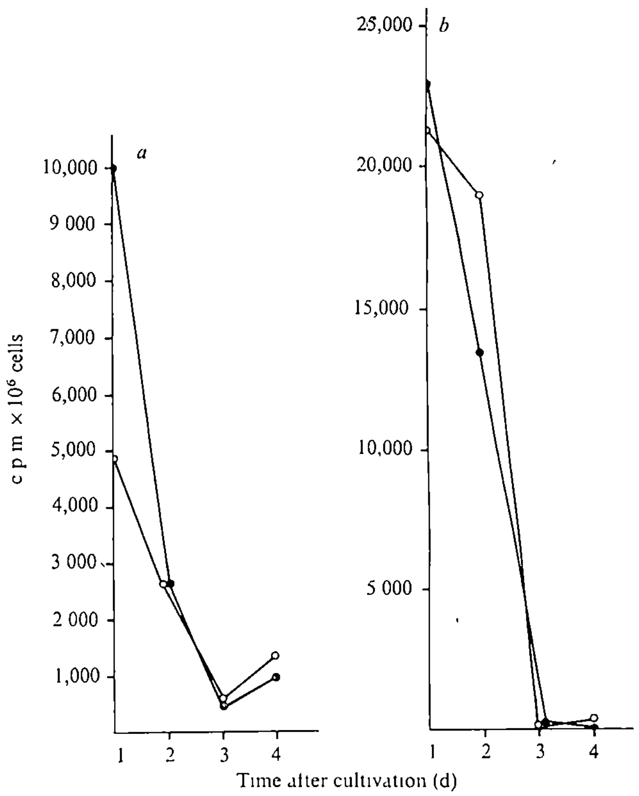

Fig 4 Incorporation of ^{14}C-labelled amino acids into *a*, acid insoluble and *b*, acid soluble fractions each day after subcultivation of human fibroblasts carried in medium with (●——●) and without (O——O) the hormone Cells were washed with phosphate-buffered saline (PBS) and then left for 15 min in PBS supplemented with 1 μCi ml^{-1} ^{14}C-labelled amino acids (Centre d'Energie Atomique, Saclay) (specific activity 0 1 Ci mmol^{-1}) The cells were scraped, washed three times in cold 10% TCA and the suspension was passed through millipore filters which were digested in Instagel The supernatants were pooled and 0 5 ml was added to 10 ml Instagel to measure the radioactivity in a liquid scintillator

The results confirm previous findings that cortisone[1] and hydrocortisone[2] prolong the lifespan of human fibroblasts *in vitro* It is interesting, however, that when hydrocortisone is withdrawn from cells which have grown beyond the lifespan of the controls, the cultures die within two passages It has been suggested[16] that cell senescence is due to an accumulation of errors at the level of protein synthesis and consequently an increased production of faulty molecules If this is the case hydrocortisone does not prevent the accumulation of errors since the cells die when the hormone is withdrawn Our data would be compatible with the error hypothesis if it is postulated that the hormone delays the deleterious effects of the presence of faulty molecules by an overall stimulation of protein synthesis, by stimulation of ribosome synthesis

Rejection of skin grafts in the nude mouse

We recently reported that in (C57BL6/Rij × A/HeJ) F$_1$ (=B6AF1) mice, in which cellular immunity was temporarily suppressed by anti-lymphocyte serum, established B10 D2 skin allografts were hyperacutely rejected after the administration of specific alloantibody and rabbit complement[1] From this it was concluded that mouse skin allografts are sensitive to the cytotoxic action of alloantibody *in vivo* provided an effective species of complement is present at the same time

Nude mice do not reject allogeneic or xenogeneic skin grafts This phenomenon is usually explained by their inability to mount an effective cellular immune response[2,3] They, therefore, might serve as an ideal model for studying the effects of antibody on the fate of skin grafts We now report preliminary results of experiments in which acute rejection of skin allografts by antibody was induced in nude mice

B10 D2 (H-2^{d}) tail skin was grafted on to nude recipients by the procedure of Billingham and Medawar[4] The nude trait was bred on to a B10 LP (H-2^{b}) background to produce a congenic line, according to the method described by Snell[5] Mice of the second backcross generation were used In all experiments donor and recipient were of the same sex The fate of the grafts was followed by macroscopic inspection Untreated nude mice carried their grafts until death without any signs of rejection To induce acute rejection, nude mice in the experimental group received a single intravenous injection of 0 5 ml B6AF1 anti-B10 D2 serum (antiserum to H-2 31)[1] and two injections of 0 25 ml of rabbit complement, on day 8 after transplantation The antiserum was prepared by injecting B6AF1 recipient mice at weekly intervals with a suspension of B10 D2 lymphoid cells in complete Freund's adjuvant After five injections the animals developed ascites and could be tapped every 1 to 2 weeks The ascites fluid was pooled and tested with B10 D2 lymphoid cells by using the trypan blue dye exclusion method Two different pools were used, both having an antibody titre of 1 512 Fresh frozen sera from rabbits were used as the source of complement

Table 1 Effects of intravenous injection of B6AF1 anti-B10 D2 serum and rabbit complement on the survival of B10 D2 skin grafts in nude mice

Group no	No of recipients	Treatment: Alloanti-serum* to H-2 31	Treatment: Rabbit† complement	No of grafts showing rejection: Complete	No of grafts showing rejection: Patchy necrosis
1	6	+	+	4	2
2	5	+	–	0	0
3	3	+	+, inactivated	0	0
4	4	–	+	0	4
5	4	–	+, absorbed	2	2
6	4	–	+, inactivated	0	0

* 0 5 ml intravenously on day 8
† 0 25 ml intravenously on day 8 Second injection of 0 25 ml 8 h later

The results are presented in Table 1 All mice which received injections of antiserum and rabbit complement showed necrotic changes of their grafts within 2 d after the injection (group 1) After 4 d four grafts were completely destroyed, while the other grafts showed extensive necrosis leaving only 40–50% of the epithelium intact After the injection of antiserum alone no changes in the grafts were seen (group 2) If rabbit complement was inactivated by heating at 56° C for 45 min before its injection with antiserum, the grafts did not show signs of rejection (group 3) But in the control experiments where fresh frozen rabbit serum was given without the antiserum, grafts showed patchy necrosis after 24–48 h (group 4) This latter finding might be the result of the presence in rabbit serum of antibodies directed against mouse cells[6] This was unlikely, since the rabbit serum was not toxic to mouse cells *in vitro* Furthermore, it could still induce graft destruction after previous absorption with B10 D2 lymphoid cells (1 ml of packed cells to 5 ml of rabbit complement) for 10 min at 4° C (group 5) After its inactivation at 56° C for 45 min the rabbit serum did not cause destruction of the grafts (group 6) The deleterious effect of heat-labile factors in the rabbit serum on the skin grafts (groups 4 and 5) might be explained by the fact that the nude mice were able to form antibodies directed against B10 D2 antigens, which could induce acute destruction of the grafts after the addition of an efficient complement to the system We, therefore, tried to demonstrate the presence of antibody activity directed against B10 D2 lymphoid cells in the sera of nude mice that carried a B10 D2 skin graft The mice were bled on day 8 after transplantation, and the sera were tested in a trypan blue assay[1] Different dilutions of serum (0 1 ml) and of cell suspension (0 1 ml, 5×10^5 cells) were incubated with 0 1 ml of rabbit complement at 37° C for 30 min Figure 1 shows that there was definite cytotoxic activity in these sera C57BL6/Rij (H-2^{b}) lymphoid cells, serving as control cells, were not lysed by the serum Several mice were tested separately, and all showed comparable antibody activity

Three conclusions can be drawn from these results First, the experiments show that skin grafts are sensitive to the cytotoxic action of alloantibody *in vivo* in a model where cell-mediated immunity is virtually absent Second, it is clear that nude mice are capable of forming antibodies directed against transplantation antigens This is in accordance with other studies where these mice were shown to

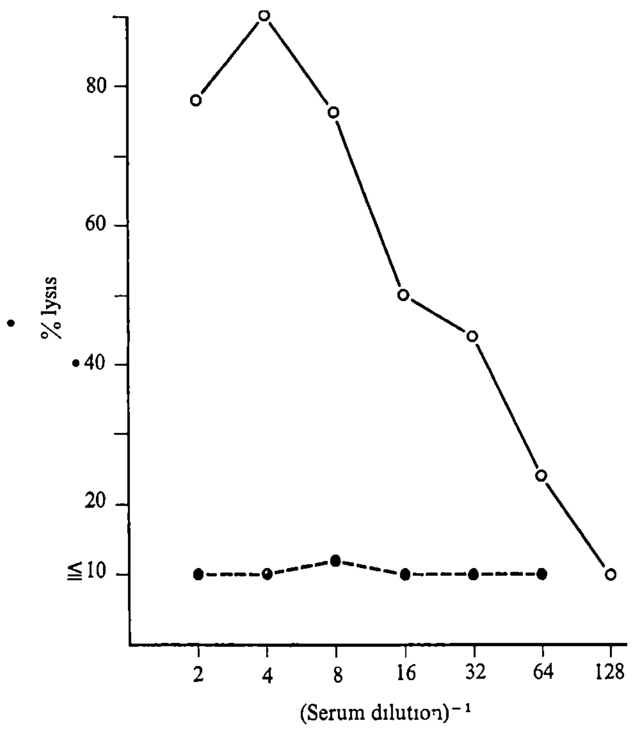

Fig. 1 Cytolysis of O, B10 D2 and ●, C57BL6/Rij lymphoid cells by nude serum and rabbit complement Mice were bled at day 8 after transplantation

form antibodies against thymus-dependent antigens, for example, sheep red blood cells[7,8] Third, the results of our experiments suggest that the antibodies, which are formed after skin grafting, are able to destroy these grafts if an efficient species of complement is added to the system The mouse native complement is very inefficient, at least in *in vitro* cytoxicity systems[9] This has been established not only in strains with a genetically determined deficiency of the C5 component of the complement system, but also in many other strains so far tested[10] It probably holds true for the species as a whole We found in our control experiments that fresh nude serum collected at day 8 after grafting, could only lyse B10 D2 cells after the addition of rabbit complement This suggests that also in this strain endogenous complement is relatively inefficient *in vitro* The indefinite survival of skin grafts in nude mice is probably not only caused by the insufficiency of the cellular immune response in these animals, but also by their lack of an efficient complement system

Spontaneous sister chromatid exchanges detected by a BUdR-labelling method

THERE is still controversy over the nature of sister chromatid exchanges detectable by autoradiography Based on the relation between the number of exchanges and dose of tritium incorporated into DNA, Gibson and Prescott[1] have concluded that all exchanges are radiation-induced and that none occurs spontaneously But such an approach has an apparent technical drawback in that the declining of sensitivity of emulsion to tritium as well as latent image fading during long autoradiographic exposure provides a definite lower limit in the number of grains formed at a given tritium dose, and hampers greatly the detection of exchanges at very low dose of incorporated tritium Another

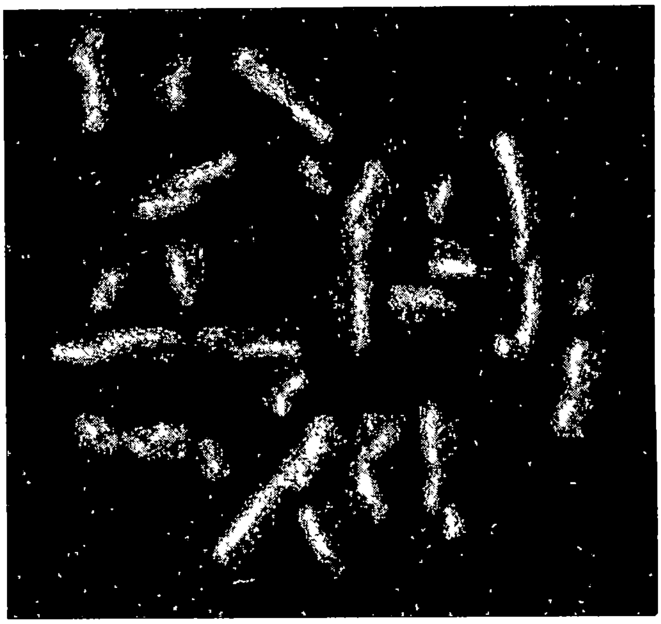

Fig 1 Fluorescence photomicrograph of metaphase chromosomes stained with acridine orange This cell had previously been labelled with 1 0 μg ml^{-1} BUdR for 26 h and fixed according to the air-drying method following 1 h Colcemid treatment × 1,600 The cell had an exceptionally large number of exchange sites (11 exchanges per cell) The brightly stained chromatid was probably composed of DNA with only one strand substituted with BUdR, the duly stained one being composed of DNA with both strands substituted with BUdR Demarcation was also possible between a chromatid containing a non-BUdR substituted DNA duplex and its sister chromatid composed of a duplex with only one strand substituted with BUdR These chromatids could be obtained by pulse-labelling cells with BUdR and then growing them for another cell cycle in the absence of BUdR before fixation Such labelling procedures were not employed in this study so as to avoid a risk of exposure of BUdR-labelled cells to visible light which would cause breaks in BU-substituted DNA, and hence, would affect the frequency of sister chromatid exchanges

difficulty may arise from the fact that the exchange frequency reaches a saturation level at a very low dose and within a very narrow dose range, so that it is difficult to determine whether a dose response curve rises linearly with or as the square of dose Extrapolation of the curve through the zero point can be misleading To detect sister chromatid exchanges, I have, following the original work of Latt[3], used a new method involving labelling of chromosomes with BUdR followed by acridine orange fluorescence staining, and have obtained results that suggest strongly the existence of spontaneous sister chromatid exchanges

A pseudodiploid Chinese hamster cell line, D-6, was grown in total darkness in culture medium[2] containing BUdR at concentrations ranging from 0 1 μg ml^{-1} to 40 μg ml^{-1} for two cell cycles and fixed for chromosome preparation Slides were stained with 0 125 mg ml^{-1} acridine orange in phosphate buffer, *p*H 6, for 5 min, washed for 15 min with and mounted in the same buffer Sister chromatids were demarcated clearly, one being stained brightly and the other dully (Fig 1) This method allowed unequivocal detection of exchanges of even very short segments of sister chromatids which would probably escape detection by the conventional autoradiographic method The mechanisms underlying this differential staining remains to be elucidated Fluorescence of acridine orange might also be affected by a quenching effect of BUdR as reported for 3325 Hochest fluorescence[3]

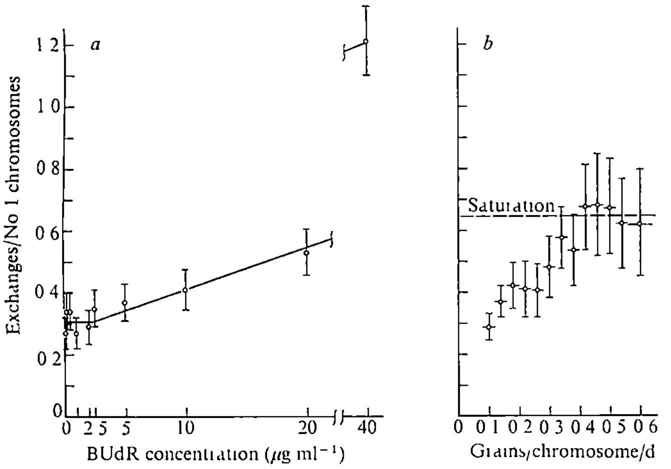

Fig 2 *a*, Sister chromatid exchanges scored in No 1 chromosomes of BUdR labelled cells Each point represents 100 chromosomes scored Range bars indicate s e m *b*, sister chromatid exchanges scored in No 1 chromasomes of cells which had been labelled with ^{3}H-thymidine (0 005 μCi ml^{-1} and 0 01 μCi ml^{-1}, specific activity 12 1 Ci mmol^{-1}) for 4 h and fixed in the second postlabelling mitosis Slides were coated with emulsion (Sakura NR-M2) and exposed for 132 d The number of grains as well as of exchange sites were scored in 755 no 1 chromosomes Range bars represent s e m and the horizontal line for each point indicates the range of grain number used to determine each point The broken line marked 'saturation' indicates the level of the maximum exchange frequency at high doses of incorporated tritium

In Fig 2*a* is plotted against BUdR concentrations the frequency of sister chromatid exchanges in No 1 chromosomes The frequency at 0 1 μg ml^{-1} was about 0 3 exchanges per chromosome and it remained constant up to 2 0 μg ml^{-1} With further increase in the concentration, the frequency started to rise and reached a level about four times of the constant level at 40 μg ml^{-1} Since BUdR labelling at concentrations lower than 0 1 μg ml^{-1} did not permit unequivocal demarcation of sister chromatids, it is uncertain whether the constant portion of the curve indicates a spontaneous exchange frequency or whether it would fall abruptly to zero at a lower concentration Results obtained with the conventional autoradiographic method are given in Fig 2*b* for comparison A dose-dependent increase in the exchange frequency was observed within the dose range 0 1 grains to 0 4 grains per chromosome per d confirming previous workers' results[1] The fate of the frequency curve at lower tritium doses is unknown, however a simple extension of the declining curve does not reach zero but meets the ordinate at a point between 0 2 and 0 3 exchanges per chromosome, which approximates to the value of the constant portion of the frequency curve obtained in BUdR-labelled cells (Fig 2*a*)

In Fig 3 the response to BUdR of sister chromatid exchanges and chromatid breaks are compared It is noticeable that frequencies of both events stayed at constant levels between 0 1 μg ml^{-1} and 1 0 μg ml^{-1}, and that the constant level of the frequency of breaks was exactly the same as that of non-BUdR treated controls These results suggest strongly that the constant portion of the frequency curve of sister chromatid exchanges might also represent a spontaneous exchange frequency Other possibilities, however, cannot yet be ruled out completely, for example (1) the genesis of sister chromatid exchanges might be completely different from that of chromatid breaks, so that the comparison of the two events in terms of their responses to BUdR might be meaningless, (2) there may be an upper limit for the BU substitution sites in DNA at low BUdR concentration[4], and such a limited level would be easily saturated, leaving the frequency of BUdR-induced sister chromatid exchanges constant

Since the exchange frequency observed between 0 1 μg ml^{-1} and 1 0 μg ml^{-1} (2 3 exchanges per cell) is the sum of exchanges formed during two successive cell cycles, the average frequency per cell generation is 1 15 If this frequency is ascribed to spontaneous exchanges, the rate may seem to be rather high considering that strand exchange

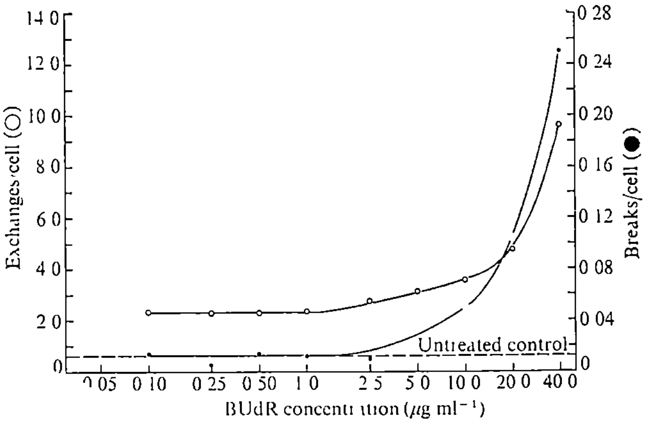

Fig 3 The number of sister chromatid exchanges per cell (○) is shown together with the frequency of breaks per cell (●) Each point on the curve for the exchange frequency was determined based on 50 acridine orange-stained cells Chromatid-type aberrations were scored in cells stained with Giemsa Each point on the frequency curve represents 200 cells scored, and is plotted in a 50-fold larger scale than that for sister chromatid exchanges Chromosome-type aberrations, both the 'derived-type' aberrations and those induced in G1, were omitted from the score Thus, the value presented in this figure is an underestimation for breaks per cell per generation Chromatid gaps were detected at almost the same frequency as that of chromatid deletions but they were omitted from this figure The broken line indicates the frequency of breaks observed in the non-BUdR treated control Whereas sister chromatid exchanges occurred randomly in every chromosomal complement at seemingly nonspecific sites, chromatid breaks as well as chromatid gaps were detected only in a few specific chromosomes such as No 1 and X The break points were mostly confined to constitutive heterochromatin regions

is an error-prone process[5]. But data showing that spontaneous DNA damage probably occurs to a significant extent in the normal conditions are accumulating. Lindahl and Nyberg[6] estimate that 2,000–10,000 purines would be lost from mammalian DNA in each cell generation. These apurinic sites seem to be repaired continuously by a maintenance system similar to the excision repair mechanism[7]. Spontaneous unscheduled DNA synthesis detectable in mammalian cells may be regarded as an outcome of such an error-correcting mechanism[8]. Although exact molecular processes leading to the formation of sister chromatid exchanges remain to be elucidated, they seem to be intimately related to mechanism of DNA repair[2]. It is uncertain yet whether sister chromatid exchanges are the outcome of a normal repair process or of errors in repair mechanisms. Whichever they may be, it is possible that one out of several thousand damaged sites in DNA would fail to restitute but provoke strand exchanges. In the same context, chromosomal breaks probably result from misrepair of DNA damage. A spontaneous frequency of breaks per cell per cell generation was about 0.012. This would mean that sister chromatid exchanges occur at a frequency about 100 times of that of chromatid breaks in the normal conditions. This ratio seems to be variable when both events are induced by exogenous agents (Fig. 3).

The observation that BUdR at high concentrations readily induced sister chromatid exchanges may be relevant to the findings that BU enhances the recombination frequency in λ phage and that a recombinational repair process is involved in BU-induced mutagenesis[9].

Non-random loss of human markers from man-mouse somatic cell hybrids

THE preferential loss of human chromosomes from hybrids between human and mouse somatic cells[1] is being used in the assignment of human gene loci to chromosomes[2]. When the experimental design does not select for the gene product under study, the assignment often assumes that the loss of chromosomes is random. For example, hybrid clones derived from mouse cells and SV40-transformed human skin fibroblasts lose the SV40-induced T antigen only when all but a few human chromosomes have been eliminated[3]. If the pattern of chromosome loss is random, these results could indicate that SV40 DNA has integrated into the DNA of several chromosomes. They might be attributable, however, to the scheduled elimination of a single pertinent human chromosome relatively late in the evolution of each clone, a possibility supported by the finding of a preferential retention of C-7 in hybrids derived from SV40-transformed human cells and a concordance of this chromosome with the presence of SV40 and T antigen[4]. Moreover, if the loss of chromosomes were directed, joint segregation of two chromosomes might occur, making it difficult to decide which of the two specified the pertinent gene product being lost simultaneously.

We have studied the pattern of loss of human enzyme and chromosome markers from hybrid clones by means of single observations of many clones, as well as observation of the evolution of individual clones, which is a more sensitive measure of directed loss. Our findings suggest that in our system the elimination of human chromosomes is indeed not random.

As the murine parent, mouse fibroblasts (3T3) lacking thymidine kinase (EC 2.7.1.21, TK) were chosen because they can be eliminated by selective medium and because

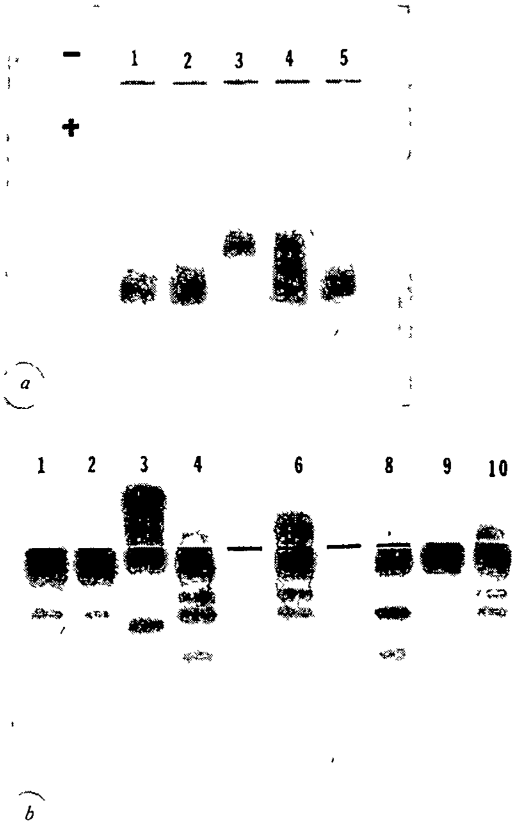

Fig. 1 Enzyme pattern of 3T3, human fibroblasts and hybrids. Electrophoresis of cell extracts[9] was performed on starch gels[10] which were stained for G6PD[11] or LDH[12]. *a*, G6PD zymogram: channel 1, 3T3, 2 and 5, hybrids without human G6PD, 3, normal human fibroblasts, 4, hybrid with human and mouse G6PD and heteropolymer. *b*, LDH zymogram, channels 1 and 2, hybrids without human LDH, 3, normal human fibroblasts, 4, 6, and 10, hybrids showing heteropolymers of human and mouse LDH A subunits and LDH B subunits presumably of human origin, 8, hybrid with LDH B subunits and no human LDH A subunits, 9, 3T3. The mouse fibroblasts have a single band of strong activity which migrates with mouse LDH 5 and therefore consists solely of LDH A subunits. The LDH B subunits of mouse and man share the same electrophoretic mobility, so that a band anodal to that of 3T3 indicates the presence of either mouse or human LDH B structural genes. Since the 3T3 parent has no B subunits, we have attributed any novel bands anodal to that of 3T3 to the presence of a human gene influencing this phenotype. Isozymes migrating cathodally to that of 3T3 were ascribed to the presence of the human LDH A subunit. Combinations of novel bands anodal and cathodal to that of 3T3 were interpreted as the simultaneous presence of human LDH subunits A and B

Table 1 Analysis of a hybrid clone maintained in HAT medium

Subculture no	LDH B	LDH A	G6PD
3	+	+	−
8	+	+	−
10	+	+	−
12	+	+	−
14	+	+	−
16	+	−	−

This table illustrates the method of analysis applied to each clone Cell extracts at various subcultures were assayed for human enzymes until the clone showed only one marker

the karyotype, containing almost exclusively acrocentric-telocentric chromosomes, cannot be confused with the human karyotype We used a clone with only a rare cell containing a biarmed chromosome To ensure a normal human parental karyotype, we used unstimulated leukocytes from a normal human male which were prepared[5] and washed twice with saline Fibroblasts (2×10^6) and leukocytes (2×10^7) were fused in suspension using β-propiolactone-inactivated Sendai virus[6] and plated in HAT selective medium[7] with amethopterin (10^{-7} M, Lederle) substituted for aminopterin

Forty HAT-resistant clones were isolated with cloning cylinders from 24 dishes between 13 and 33 d after fusion Multiple clones from a single dish were transferred individually 13 d after fusion As they were all about the same size, they presumably originated from different heterokaryons When these clones became confluent, half of each was plated into a dish containing HAT and the other half into a dish containing a non-selective medium, HT (HAT without amethopterin) Thus we compared the effect of amethopterin on the pattern of marker elimination At each subsequent subculture, one-fifth of the cells was used to continue the line and four-fifths were divided between two dishes, one for enzyme electrophoresis and one for chromosome preparations Lactate dehydrogenase subunit A (LDH A) and subunit (LDH B) (both EC 1 1 1 27) and glucose-6-phosphate dehydrogenase (G6PD, EC 1 1 1 49) were chosen as enzyme markers because mouse and human forms could be distinguished, because each is specified by a different chromosome[8] and because they could be analysed simultaneously

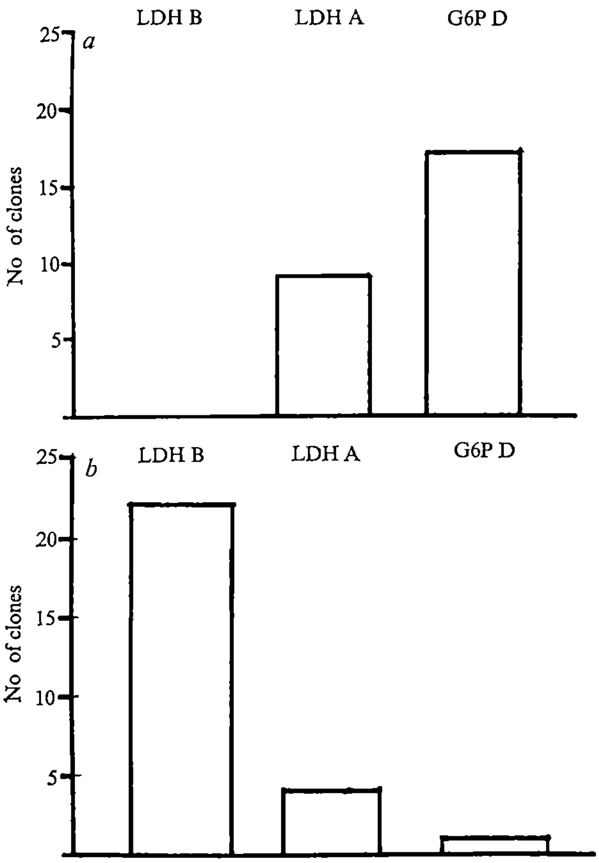

Fig. 2 Pattern of marker loss determined by serial observations of individual clones *a*, Number of clones losing each of the enzyme markers first, *b*, number of clones losing each of the enzyme markers last.

The characteristic G6PD patterns seen in our hybrids are shown in Fig 1*a* Only patterns with the G6PD heteropolymer were scored as positive for human G6PD Some of the LDH isozyme patterns observed are presented in Fig 1*b*

Thirty of the HAT-resistant colonies survived transfer and showed human isozymes and/or human marker chromosomes Each clone was analysed at various stages of its evolution until it had only one of the three enzyme markers (Table 1) Table 2 gives the frequency of the human enzymes in all hybrid clones analysed, including serial determinations of each during clonal evolution The distribution of the frequencies indicates that markers were not lost randomly

The predominance of LDH B reflects the timing of its elimination from individual hybrid clones (Fig 2*a* and *b*) Since amethopterin in the medium did not affect the incidence of the human LDH subunits and only slightly influenced the retention of human G6PD (Table 2), our observations from the clonal sublines maintained in the two media have been pooled The first enzyme lost was human G6PD in 17 of the 26 clones analysed No clone lost human LDH B first (Fig 2*a*) The last of the three human enzyme markers lost was LDH B in 22 out of 27 clones analysed (Fig 2*b*) The number of clones either losing G6PD first or retaining LDH B until last is significantly different from the numbers expected if the loss were random ($P<0$ 01) Thus a distinct pattern of enzyme elimination was observed, characterised by the relatively early loss of human G6PD and the retention of LDH B

Table 2 Frequency of human enzyme markers in hybrid clones

	Enzyme		
Medium	LDH B	LDH A	G6PD
HAT	88% (80)*	68% (81)	38% (69)
HT	86% (109)	62% (107)	27% (106)
Total	87% (189)	64% (188)	31% (175)

*Number of different clonal extracts analysed for the presence of the pertinent marker The extracts came from a total of 30 clones assayed at various times during their propagation and no duplicates are included

To test whether our analysis had been influenced by a differential sensitivity of the assay for the three enzymes, we performed reconstruction experiments with parent cell lines After starch gel electrophoresis, the distribution of LDH A and B subunits in extracts of human leukocytes is approximately equal To determine the relative sensitivity of the electrophoretic assay, we used human skin fibroblasts rather than leukocytes, as the former seemed more closely to simulate the intracellular environment in the hybrid Various proportions of fibroblasts were mixed with 3T3 cells and the extracts were subjected to electrophoresis In our gel system human fibroblasts have predominantly LDH A subunits Both LDH A and G6PD were equally detectable when as little as 5% of the mixture was human extract Since the LDH B was slightly less visible than the other two marker enzymes in these preparations, the observed pattern of enzyme loss cannot be explained on the basis of differential sensitivity of the assay

The early loss of G6PD is not surprising, since only one human X chromosome is present in the hybrid and since our data indicate that this chromosome provided no great selective advantage in HAT medium. Nevertheless, the preferential retention of human LDH B compared with LDH A cannot be explained on the basis of chromosome dose and is evidence of a directed pattern of chromosome loss

The hybrid clones were analysed for the presence of human chromosomes 1, 3, 6, 7, 9, 11, 12, and Y because their distinctive quinacrine mustard (QM) fluorescence patterns[13] facilitated discrimination from rearranged mouse chromosomes The 3T3 clone used as mouse parent contained an occasional submetacentric chromosome at the time of fusion and these did not increase significantly Moreover, no mouse chromosomes had fluorescent patterns that could be confused with the human chromosome markers The karyotype of the human parent was characterised by intensely fluorescent centromeres of chromosome 3 and the terminal long arm of the Y The 52 hybrid karyotypes analysed included 1 to 4 cells from each of 16 clones Most hybrid cells had two sets of 3T3 chromosomes

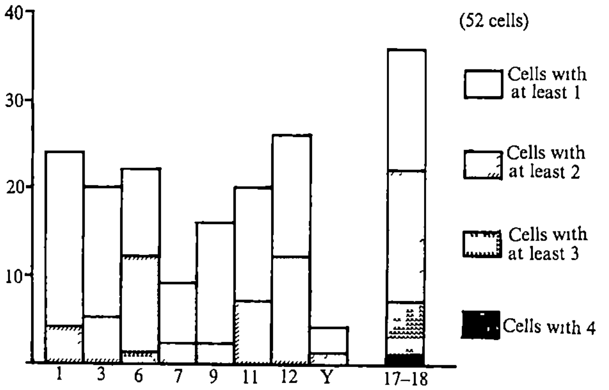

Fig 3 Frequency of human chromosome markers in hybrid cells

Because it is difficult to distinguish invariably chromosome E17 from E18, we have referred to a submetracentric E group chromosome as 17–18 However, we believe the chromosome is E17, since the thymidine kinase it specifies is essential to the survival of the hybrid cell

Except for chromosome 17, the incidence of human chromosome markers did not differ significantly in HAT and non-selective medium Therefore, we have combined observations of clonal sublines maintained in the two media for the analysis of the frequency of the various human chromosome markers (Fig 3) The least frequently observed chromosome was the Y, possibly because the parent line contained only one The most frequent was the chromosome specifying thymidine kinase[14] as a result of its selective retention by the culture conditions Moreover, we noted significant variation ($P<0\ 01$) in the frequency of the autosomes not obviously favoured or disfavoured by the experimental conditions Therefore, the distribution of chromosomes in the hybrid cells is not that expected if all chromosomes had an equal chance of inclusion in the hybrid genome In addition, the presence of human LDH subunits, together with the prevalence of chromosome C-11 and C-12 in these hybrids, supports the assignment of LDH A and LDH B to these two chromosomes[15,16]

Data from studies of other hybrids suggest to us further evidence of non-random human marker loss None of the nine clones derived by Santachiara *et al*[17] from fusion of 3T3 with human leukocytes of female origin had human G6PD, while four had human LDH A and seven had human LDH B Allderdice *et al*[18] studied the karyotype of man–mouse hybrid clones where selection favoured retention of the human X Of the chromosome markers used by us and Allderdice *et al*, C-12 was second in incidence only to the X, while C-11 was also frequently observed Further evidence of preferential inclusion of chromosomes specifying LDH in the hybrid is that a disproportionate number of autosomal linkage assignments made on the basis of hybrids involved the joint segregation of the pertinent marker with A or B subunits of LDH

The basis for the directed loss remains obscure, but may be related to the nature of the gene products specified by the chromosomes preferentially lost In this case one might predict that the pattern of elimination could vary with the parental cells and culture conditions used

Isolation and *in vitro* translation of soybean leghaemoglobin mRNA

LEGHAEMOGLOBIN (Lb), a myoglobin-like protein, is found in large quantities in the root nodules which result from the symbiotic association between the bacterium *Rhizobium* and plants of the family Leguminosae The probable function of Lb is the regulation of intranodule oxygen tension[1] and its presence is correlated with rhizobial nitrogenase[2] The haem prosthetic group of Lb is of bacterial origin[3] and the plant contains the genetic determinants for the apoprotein[4,5] Soybean Lb consists of two major components of different electrophoretic mobility[6] The faster component (LbF) is composed of 139 amino acids, has a molecular weight of 15,600 and contains an amino terminal glycine residue, while the slower component (LbS) is com-

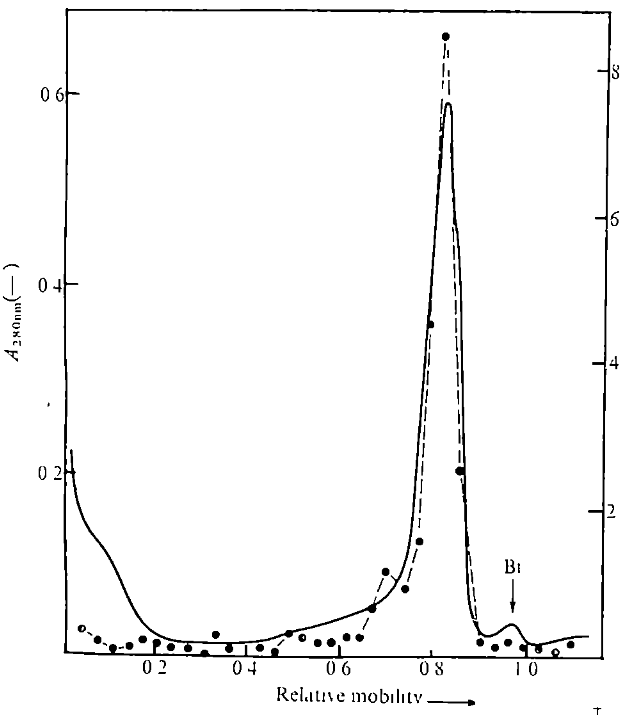

Fig. 1 SDS gel electrophoresis of the immunoprecipitated product from *in vitro* protein synthesis with nodule polysomes. Polysomes were isolated from nodules by homogenising the tissue in high ionic strength buffer (150 mM Tris-acetate, 20 mM KCl, 5 mM Mg acetate, 200 mM sucrose, 5 mM mercaptoethanol, 0.4% Nonidet P-40 detergent, *p*H 8.5). The polysomes were centrifuged through a 2 ml sucrose cushion (1.5 M sucrose, 50 mM Tris-acetate, 20mM KCl, 5 mM Mg acetate, *p*H 8.5), for 2 h at 105,000*g*, and resuspended in 10 mM Tris-HCl, 20 mM KCl, 1 mM Mg acetate and 20% glycerol. 4–8 A_{260} units of polysomes were incubated with the standard amino acid incorporation system in 400 μl consisting of 80 μl of postribosomal wheat supernatant, 45 mM KCl, 3.5 mM Mg acetate, 1 mM ATP, 25 μM GTP, 8 mM creatine phosphate, 16 μg creatine phosphate kinase, 25 mM Tris-acetate, *p*H 8.0, 2 mM dithiothreitol, 2 μCi 4,5-^{3}H-L-leucine (specific activity 64 Ci mmol^{-1}). After 60 min of incubation at 30° C carrier antigen was added (2 μg each of LbF and LbS) and ribosomes were removed by centrifugation. The postribosomal supernatant was reacted with anti-Lb serum for 60 min at 30° C. The immunoprecipitate was washed three times with phosphate-buffered saline, solubilised in SDS buffer and subjected to electrophoresis in 10% SDS gels[8]. Gels were cut into 2 mm slices and dissolved in 0.8 ml of 30% H_2O_2 at 55° C and counted in PCS (Amersham, Searle). The absorbance at 280 nm was determined on an identical gel run with Lb as a marker (50 μg each of LbS and LbF).

posed of 143 amino acids, has a molecular weight of 15,900 and contains an amino terminal valine residue. Because of these differences LbF and LbS are presumed to be different gene products[7]. Thus they are useful markers in studies on the transfer of plant genes involved in symbiosis to other plants.

In an attempt to elucidate the interaction between plant and bacteria in the expression of Lb genes we have isolated a poly(A)-containing 9S–12S mRNA from polysomes of soybean root nodules and translated it in a wheat embryo cell-free system. This mRNA can initiate protein synthesis on 80S wheat ribosomes and release completed protein chains which react with monospecific antibodies to Lb. Translation of Lb mRNA is not dependent on the presence of haem or any other factor from soybean root nodules.

Rhizobium japonicum strain 61A76 (supplied by Dr Joe Burton, Nitragin Co., Milwaukee) was grown in a liquid culture medium composed of (g l^{-1}) K_2HPO_4, 0.5, $MgSO_4 \cdot 7H_2O$, 0.2, NaCl, 0.1, yeast extract, 1.0, mannitol 10.0 and adjusted to *p*H 6.6. Bacteria were grown at 27° C with constant shaking and subcultured every 7 d. Soybean (*Glycine max*, var. Kanrich), was grown on Vermiculite in a controlled environment room under a 12 h photoperiod at 27° C and a night temperature of 21° C, and provided with a nitrogen-free nutrient solution[3]. Seeds were inoculated with a suspension of rhizobia in 5% sucrose before sowing and root nodules were collected 3–4 weeks later. The nodules were frozen immediately in liquid nitrogen and those 2–4 mm in diameter were used, except where mentioned otherwise.

Polysomes were prepared for translation experiments as outlined in the legend to Fig. 1. To test their capacity for protein synthesis, polysomes were incubated in a cell-free system containing postribosomal supernatant from wheat embryos[9–11]. Under these conditions polysomes primarily complete and release nascent protein chains (our unpublished data). The radioactive product from this system reacted with anti-Lb serum obtained from rabbits immunised with electrophoretically homogeneous Lb. Since the antiserum was monospecific and the radioactive antigen (after solubilisation from the antigen-antibody complex) migrated with

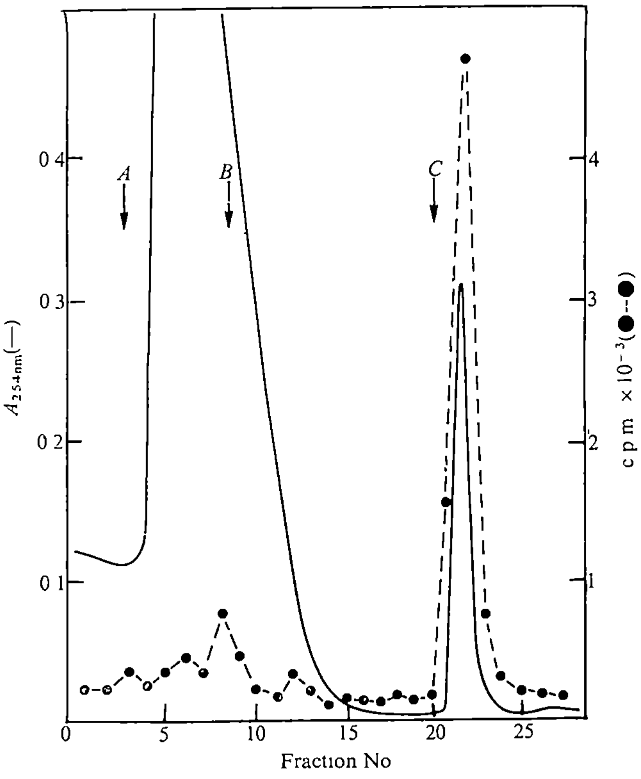

Fig. 2 Isolation of poly(A) containing mRNA by oligo(dT)-cellulose chromatography. Polysomes, prepared as for Fig. 1, were suspended in buffer (0.1 M Tris-acetate, 0.1 M NaCl, 2 mM Na EDTA, *p*H 9.0) and made 1% with respect to SDS at room temperature. Total polysomal RNA was extracted and chromatographed as described by Aviv and Leder[12]. The sample was applied at room temperature in SDS buffer (*A*). SDS was removed in the wash buffer (*B*). Poly(A) containing RNA was eluted with 0.01 M Tris-acetate, *p*H 7.4 (*C*). Absorbance at 254 nm was monitored with a Beckman DB spectrophotometer. An aliquot of each fraction was incubated with 5 nCi of ^{3}H-poly(U) in a final volume of 0.5 ml containing 0.2 M NaCl, 5 mM Mg acetate, 10 mM Tris-acetate, *p*H 7.4. Hybridisation was allowed to proceed for 15 min at 25° C, after which each fraction was treated with 20 μl of pancreatic RNase (20 μg ml^{-1}) for 30 min at 25° C. The reaction was terminated by adding cold 5% trichloroacetic acid (TCA). Carrier RNA was then added and the precipitates collected on Whatman GF/C filters, washed with cold 5% TCA, dried, and their radioactivity measured. No ^{3}H-poly(U) binding was observed with controls which consisted of equivalent, amounts of wheat ribosomes and/or wheat tRNA. The fractions which eluted with buffer (*C*) contained most of the poly(A) containing RNA, were pooled and made 2% with respect to potassium acetate, *p*H 5.5. They were then precipitated with 2.5 volumes of ethanol at −20° C

Table 1 Translation of root nodule RNA fractions and the immunoprecipitation of the products

Experiment	RNA	Total incorporation (c p m)	Anti-Lb serum precipitable radioactivity (c p m)	% of total radioactivity precipitated by anti-Lb serum
1	Total polysomal RNA	10,716	2,679	25
2	*RNA not containing poly (A)	237	—	—
	*Total poly (A)-containing RNA	40,320	11,290	28
3	†9S RNA	27,250	15,465	57
	†12S RNA	38,000	12,780	33

RNA fractions were translated in the standard amino acid incorporating system from wheat embryos in a total volume of 200 μl (experiment 2) or 400 μl (experiments 1 and 3) as described in Fig 1 After 60 min of incubation at 30° C an aliquot of the postribosomal supernatant was incubated with anti-Lb serum and processed as in Fig 1 Aliquots treated with normal rabbit serum precipitated 150–250 c p m in all cases *Prepared by oligo(dT)-cellulose chromatography (Fig 2)

†From sucrose gradients (Fig 4)

carrier Lb on sodium dodecyl sulphate (SDS) gels (Fig 1) we concluded that these polysomes contained mRNA which codes for soybean Lb

RNA was extracted from nodule polysomes and fractionated on a column of oligo (dT)-cellulose[12] The RNA which eluted from the column with low salt buffer was found, by hybridisation with ^{3}H-poly(U), to have most of the poly(A)-containing RNA (Fig 2)

The RNA fractions from the column were tested for ability to support protein synthesis in the wheat embryo cell-free system, which in addition to ribosomes contains all the factors necessary for protein synthesis but has very little endogenous mRNA activity[9–11] Only the poly(A)-containing RNA supported the incorporation of ^{3}H-leucine into released polypeptide chains (Table 1) Other RNA fractions were ineffective by themselves and were not inhibitory when added together with poly(A)-containing RNA Of the soluble radioactive products synthesised in the presence of the poly(A)-containing RNA, 25–30% was precipitated by anti-Lb serum The immunoprecipitated radioactivity migrated with carrier Lb on SDS gels (Fig 3), similar to the products made by total polysomes (Fig 1)

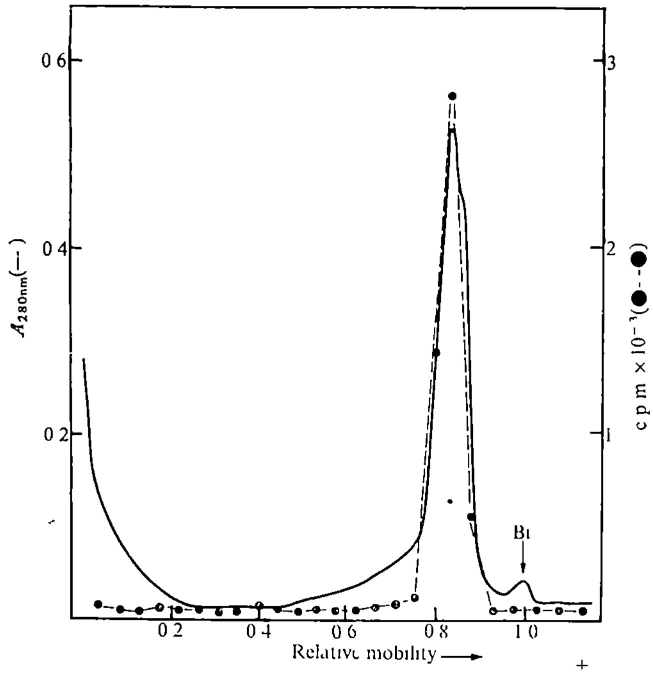

Fig. 3 SDS gel electrophoresis of the immunoprecipitated product from *in vitro* translation of leghaemoglobin mRNA Poly(A) containing RNA prepared from polysomes as in Fig 2 was translated in the standard wheat embyro amino acid incorporating system in a total volume of 400 μl (Fig 1) containing 4 A_{260} units of wheat embryo ribosomes After incubation, the postribosomal supernatant was reacted with anti-Lb serum and analysed in SDS gel as described in Fig 1.

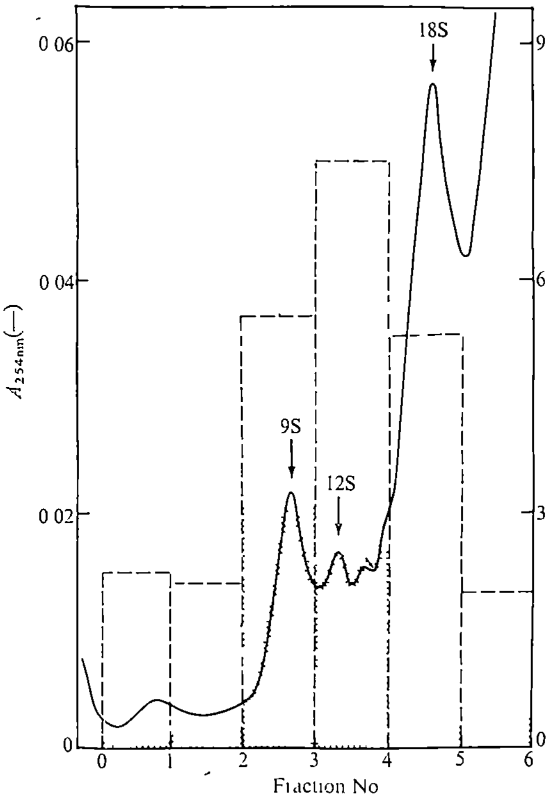

Fig 4 Sucrose gradient centrifugation of poly(A) containing RNA from soybean root nodules Poly(A) containing RNA was isolated (Fig 2), mixed with 100 μg of carrier RNA and layered on a 10 ml, 10–30% (w/v) sucrose gradient in 50mM Tris-acetate, 100 mM NaCl, 100 mM Na acetate, *p*H 8 5 Centrifugation was for 14 h at 39,000 r p m at 2° C in a Beckman SW 41 rotor Gradients were fractionated and A_{254} was monitored RNA from each fraction was precipitated at −20° C for 24 h with 2 5 volumes of ethanol The RNA was collected and dissolved in 40 μl of water Aliquots of these RNA fractions were translated in the standard amino acid incorporating system in a total volume of 200 μl containing 2 A_{260} units of wheat ribosomes (Fig 1) After incubation, an aliquot of each postribosomal supernatant was precipitated with hot 5% TCA and radioactivity was determined (total counts, open columns) while another aliquot was incubated with anti-Lb serum (shaded columns) for 60 min at 30° C The immunoprecipitate was washed twice with phosphate buffered saline and collected on Whatman GF/C filters Filters were washed with 5% TCA, dried and their radioactivity determined (anti Lb counts)

Analysis of the poly(A)-containing RNA by sucrose gradient centrifugation showed that it had mainly 9S and 12S components (Fig 4) Translation of the individual fractions from the gradient demonstrated that the 9S and 12S fractions were the most active in supporting protein synthesis in the wheat embryo system and the products from these fractions had the highest reactivity with anti-Lb serum (Fig 4 and Table 1) The S value of these RNA fractions was confirmed by electrophoresis in 2 8% acrylamide gels[13] The position of RNA in the gels was determined by ^{3}H-poly(U) hybridisation to fractions eluted from 2 mm gel slices

Since the two species of Lb in soybean root nodules (LbS and LbF) are equally reactive with Lb antisera and migrate together in SDS gels (Figs 1 and 3) it was not possible to determine whether the poly(A)-containing mRNA codes for one or both leghaemoglobins To answer this question the radioactive product was analysed with carrier LbS and LbF by disc electrophoresis[14]. Figure 5 shows that the bulk of the radioactivity accompanied the LbS whereas relatively little was associated with the LbF. The fact that the radioactivity was in Lb was confirmed by its reactivity with anti-Lb serum after elution of the corresponding sections from a duplicate gel. At present we have no explanation for the selective synthesis of LbS, since extracts of nodules of all ages contain more LbF than LbS (our unpublished data).

For its *in vitro* translation, Lb mRNA does not seem to require any specific factors which may arise in the nodule as a result of the symbiosis. Preliminary experiments suggest that the translation of Lb mRNA in the wheat embryo cell-free system is not stimulated by the addition of haem. Furthermore, it is unlikely that the system responded to endogenous haem, since the addition of human serum albumin, which can bind haem avidly[15], was without effect. It has also been shown that the translation of rabbit globin mRNA in the wheat embryo system does not require haem[16].

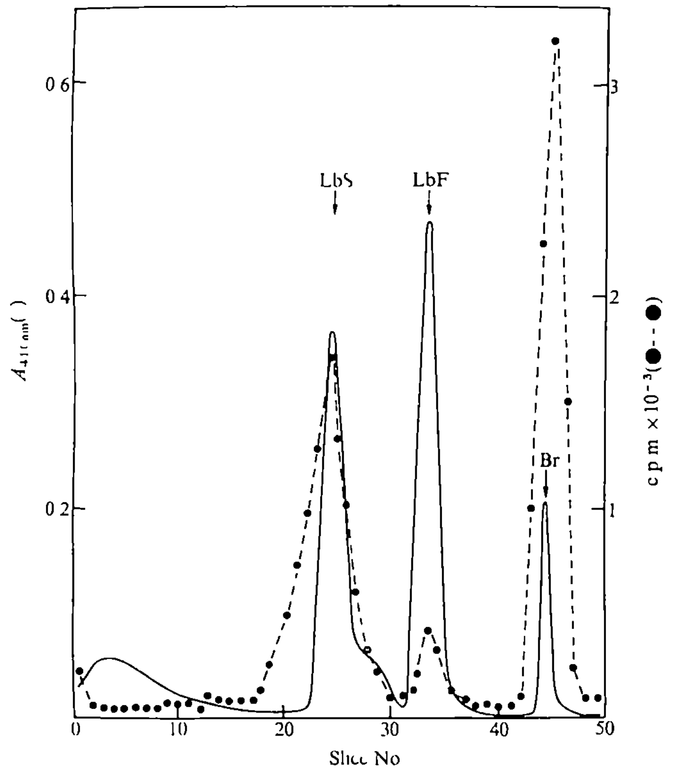

Fig. 5 Disc gel electrophoresis of the products made by poly(A)-containing RNA. The poly(A) containing RNA from Fig. 2 was translated in the standard wheat embyro system as described in Fig. 1 and the postribosomal supernatant containing released products was mixed with 10 μg each of LbS and LbF and analysed by electrophoresis (4 mA per tube) on 7.5% acrylamide gels[14]. After electrophoresis, gels were scanned at 410 nm in a Gilford spectrophotometer and their associated radioactivity was measured by fractionating the gels into 1 mm slices as described in Fig. 1. Br, bromophenol blue marker.

Although several eukaryotic mRNAs have been isolated and translated in various cell-free systems, this is the first report of the isolation and *in vitro* translation of a plant mRNA. Our experiments demonstrate that, like animal and viral mRNA, plant mRNA can be translated in a cell-free system derived from an unrelated species. Although isolated from a prokaryote-eukaryote symbiosis, Lb mRNA seems to be of plant origin since, like other eukaryotic messengers it contains poly(A) and is associated with 80S ribosomes[17–20]. These results are consistent with other evidence that the plant contains the genes for Lb[4,5]. Hybridisation of Lb mRNA with DNA from uninfected soybean plants should provide definitive proof of the location of the Lb gene.

We thank Dr G. A. Maclachlan for laboratory facilities, Dr W. R. Jeffery for advice on the poly(U) hybridisation assay, and Dr D. Fromson for helpful discussions. This work was supported by grants from the National Research Council of Canada to H. M. S. and Dr G. A. Maclachlan.

Differential staining of human and mouse chromosomes in interspecific cell hybrids

VIRUS-MEDIATED fusion of somatic cells to produce interspecific cell hybrids has proved to be a most valuable technique for biological research[1]. Such crosses often undergo an initial fairly random loss of many chromosomes of one parent before karyotypic stability is reached. This property can be used to generate clones of cells each containing a small selection of human chromosomes in a background genotype of some other species. Comparisons of such cell lines provide a form of segregation analysis which can substitute for more traditional genetic methods, particularly in studies on man where classical genetic methodology is difficult to apply.

Among the many interesting applications of this technique, a particularly prolific field has been the mapping of the human genome[2]. By studying the cosegregation of human gene products in a number of hybrid clones, linkage of the gene loci determining those products can be inferred

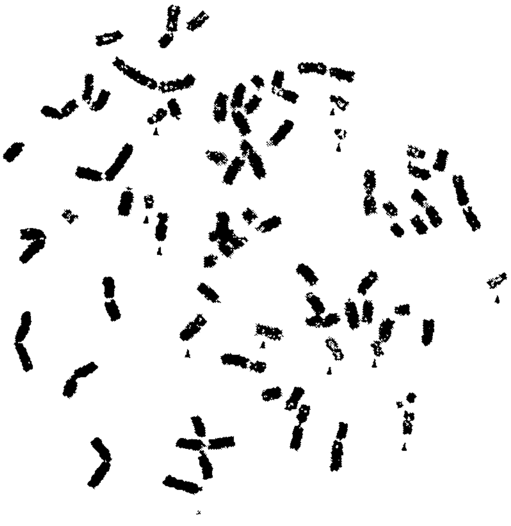

Fig 1 Metaphase of interspecific hybrid between mouse cell line (IR) and human lymphocytes Human chromosomes (arrowed) are pale blue, some having red paracentromeric heterochromatin Mouse chromosomes have pale blue centromeric heterochromatin and red euchromatic arms

If the karyotypes of the cell lines are established, gene loci can be assigned to particular chromosomes

The availability of well characterised cell lines and extensive genetic knowledge of the species, make mouse cells particularly suitable as 'carriers' in such studies A major disadvantage, however, is the difficulty of characterising the karyotypes of mouse–human cell hybrids Human acrocentrics, and abnormal chromosomes, are difficult to pick out of the complex and variable mouse background We have been investigating means of differentiating human from mouse chromosomes, to allow a fairly rapid screening of cell lines for the number and morphology of human chromosomes carried With this knowledge, formal identification of the individual chromosomes concerned using various chromosome banding techniques is greatly simplified We report here that mouse chromosomes, and the chromosomes of permanent mouse cell lines, show an almost exact reversal of the Giemsa-11 staining pattern found for human chromosomes, and that these staining characteristics are retained in mouse–human hybrid cells

The Giemsa-11 staining technique[3,4] highlights specific regions of constitutive heterochromatin in the human karyotype In optimal preparations, the chromosomes are a bluish colour, with red differentiation of paracentromeric regions of chromosomes 1, 4, 5, 7, 9, 10, 13, 14, 15, 20, 21 and 22 Parts of the Y chromosome are also stained Mouse chromosomes stain a dark magenta, with pale blue centromeres In hybrids, those human chromosomes which contain G-11 positive material are most readily identified, being pale blue with red paracentromeric regions (Fig 1) Even those human chromosomes such as the X, which have no G-11 positive material, can be differentiated from the surrounding mouse chromosomes by their lighter colour, and by the absence of the markedly paler centromere regions characteristic of mouse chromosomes

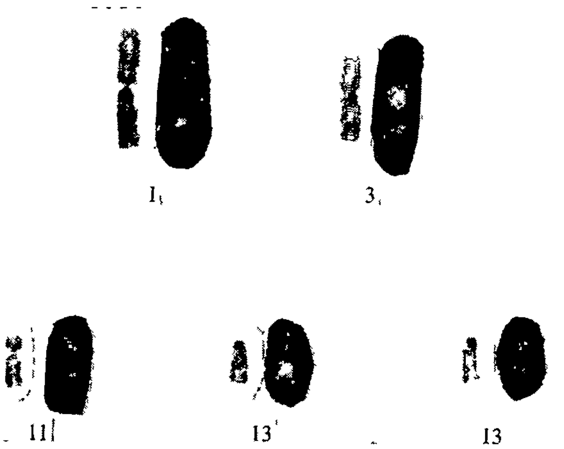

Fig. 2 Human chromosomes from a single mouse–human hybrid metaphase, identified by G-11 staining (left) and restained with quinacrine (right)

The staining procedure is similar to that used on diploid human cells Colcemid-arrested metaphases are treated for 15–20 min in 0 075 M KCl, fixed in 3 1 methanol acetic acid, and air dried Flame dried slides can also be used Slides are left for about 1 week at room temperature, or for 2 d in a dry oven at 60° C, before staining The staining solution is a 1/50 aqueous dilution of Giemsa (Harleco), adjusted to pH 11 0 with NaOH Optimal staining is usually achieved in 10–20 min Slides are then rinsed in pH 6 8 phosphate buffer and allowed to dry Unmounted slides can be examined and photographed with oil immersion objectives After removing the oil with xylene, they can be destained in two changes of acetic methanol and satisfactorily restained with quinacrine or G-banded using trypsin[5]

As with all chromosome banding techniques, the quality of staining is somewhat erratic But altering the staining time, and the pH and dye concentration of the staining solution, we have achieved success in 14 out of 15 hybrid clones studied The identity of the chromosomes concerned has been established by re-examining previously photographed metaphases under quinacrine fluorescence, (Fig 2), as well as by formally karyotyping Giemsa banded cells of the same clones One clone, known on biochemical evidence to contain only part of a human X chromosome, was found to have a chromosome which stained in part as a mouse chromosome and in part as a human chromosome (Fig 3) The pale staining of human euchromatin cannot be distinguished from mouse constitutive heterochromatin and although this chromosome has not been seen in either the parent mouse line or any of the 11 other hybrid clones derived from it, its characterisation as a mouse–human translocation cannot yet be regarded as final

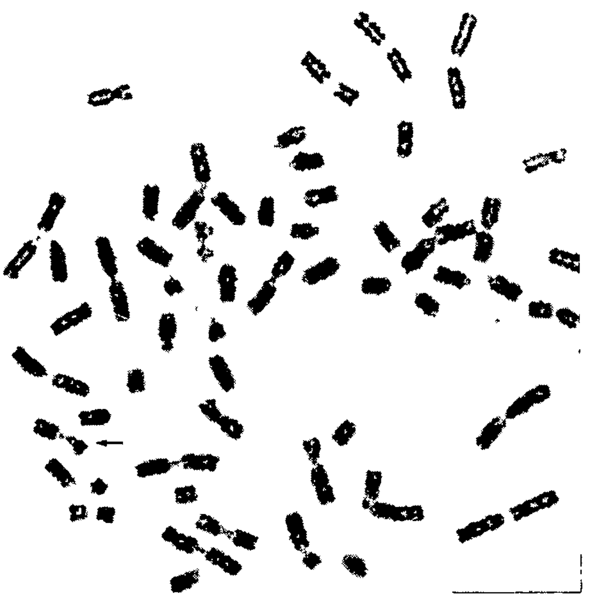

Fig 3 Partial metaphase of mouse–human hybrid (clone 2W1-R70) showing possible interspecific translocation chromosome (arrowed)

The physicochemical basis of the G-11 staining reaction remains obscure On human chromosomes, it was previously noted[3] that staining in alkaline Giemsa rapidly leads to an overall pale blue coloration suggestive of methylene blue, with the subsequent development of specific red staining at particular chromosomal sites This accords with the work of Summer and Evans[6] on G-banding, which led them to propose that the magenta colour of chromosome bands stained with Giemsa was due to the *in situ* formation of a molecular complex of methylene blue and eosin Giemsa-banding can also be produced by simple manipulation of the *p*H of the staining solution[7], suggesting that as the alkalinity of the stain is raised, an increasing amount of human chromatin loses the capacity to form such magenta dye complexes

The ability to form red dye complexes at high *p*H is clearly not a particular property of constitutive heterochromatin or of highly repetitious DNA sequences, since mouse heterochromatin exhibits the same colour changes as human euchromatin even when the chromosomes are in the same cell It seems likely that the change in staining is not due to a direct influence of *p*H on the process of dye binding, but is mediated by an alteration in the structure of particular regions of chromatin This could be as simple as a disruption of the compact coiling of the chromatin fibrils, due to an effect of *p*H on associated structural proteins, but the real nature of the process is still completely unknown

It is, however, clear that the G-11 technique can serve as a most useful method for the primary analysis of the chromosomes of human–mouse cell hybrids Coupled with re-examination of photographed metaphases under quinacrine fluorescence, it has provided us with an acceptable technique for the identification of human chromosomes against a mouse chromosome background Whether it will prove useful for other combinations of species has not yet been determined

T lymphoblastoid cell lines from Marek's disease lymphomas

MAREK'S disease (MD) is a contagious lymphoproliferative condition of chickens caused by a herpesvirus It has the distinction of being the first commonly occurring tumour to be controlled by vaccination In its complex pathology and aetiology the disease bears remarkable similarities to Burkitt's lymphoma (BL), but the potential of MD as a model of human lymphoproliferative disease and of herpesvirus-induced neoplasia has not been fully realised One obstacle has been the lack of any established cell lines[1] This contrasts with studies on BL, where, in the absence of suitable experimental animals, attention has been focused on the growth of tumour cells *in vitro*[2] A continuous cell culture from a lymphoma of MD has recently, however, been reported[3] We now report the establishment of two cell lines from MD lymphomas and their characterisation as T cells

The approach used was that found to be successful in the long term culture of lymphocytes from BL biopsies[4] Ovarian lymphomas were collected from experimentally infected birds at about 5 weeks of age Single cell suspensions were prepared either by gentle teasing of the tumours or by agitation in 1% trypsin The suspensions were adjusted to 5×10^6 cells ml^{-1} and cultures of 5 ml volume were incubated in screw cap glass universal bottles at either 37° C or at 40° C Cultures of lymphocytes separated from heparinised blood samples were initiated in a similar way The medium used was RPMI 1640 supplemented with 20% foetal calf serum (FCS), and 10% tryptose phosphate broth All cultures were set up in replicates according to the number of cells available

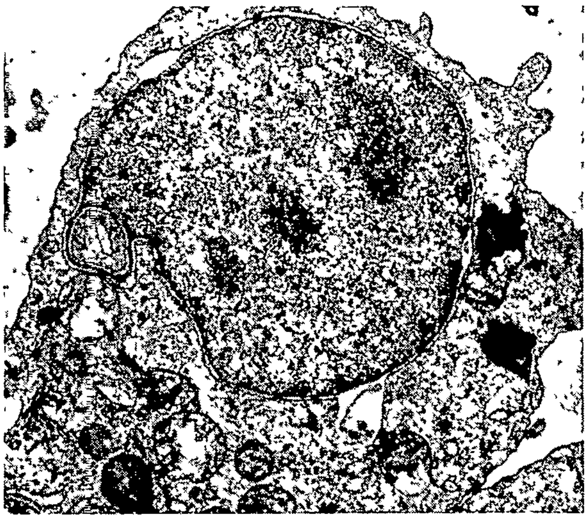

Fig 1 Typical lymphoblast of HPRS Line 1 The rounded nucleus has a projection of the nuclear envelope The cytoplasm contains many ribosomes, several mitochondria and osmiophilic bodies, but sparse endoplasmic reticulum (× 11,250)

Cultures were refed by replacing half of the supernatant medium, taking care not to disturb the cells, with fresh medium every 2 d for the first week of culture, and thereafter weekly

Several cultures gave rise to a profuse growth of adherent fibroblast-like cells Cultures were examined regularly for evidence of the growth of free floating cells One culture derived from an ovarian tumour was found to be growing in this manner 31 d after initiation This culture has now been growing for 29 weeks and is designated 'HPRS Line 1'. A second culture (HPRS Line 2), also from a lymphoma, was found to be multiplying 92 d after initiation This culture has now been growing for 13 weeks Cultures were divided into two every 7 or 10 d according to their appearance

In the growth of both cultures a high proportion of dead cells has been consistently observed Medium supplemented with 30% FCS or with 15% FCS and 15% chick serum supported growth, but did not correct this problem The cells were easily damaged by handling Growth was better at 40° C than at 37° C

The cells were never attached to glass They appeared singly or in pairs but not in clumps Most cells were round but a few had projections making them elongated The cells ranged in size, 'when measured in the living state, from 5 µm to 12 µm with a mean of 8 µm In smears the cells had large nuclei and a rim of intensely basophilic cytoplasm containing vacuoles Some large cells contained two nuclei Nucleoli were not seen

Ultrastructurally HPRS Line 1 cells were similar to cells seen in MD lymphomas (Fig 1) The nucleus was round or oval and sometimes slightly indented A nucleolus was occasionally seen and about 3% of the cells showed projections of the nuclear envelope (Fig 1) The cytoplasm contained many ribosomes, some of which were in the form of polyribosomes Several mitochondria were present, but the endoplasmic reticulum, which was often rough surfaced, was sparse A Golgi apparatus was seen in some cells Centrioles were fairly frequent and were often accompanied by spindle tubules Small, often irregularly shaped osmiophilic bodies, probably of lipid were normally present in the cytoplasm Occasional vacuoles were seen, and a small number of cells had parallel arrays of annulate lamellae in the cytoplasm Cells containing immature herpesvirus particles were seen rarely

HPRS Line 1 cells acted as plaque-forming infectious units to chick kidney cell monolayers Estimates of infectivity, each on several different subcultures, were made at four different times These gave values of 80, 1,048, 233, 1,278 plaque-forming units per million viable cells The cell lines do not produce cell free virus

Two cultures capable of long term growth have arisen from a total of 120 cultures, derived from 49 tumours and 11 blood samples A further 32 lymphocyte preparations from normal blood failed to grow in long term culture This contrasts with the relative ease with which lymphoblastoid lines may be established from human blood and BL biopsies, and suggests that the method described is not optimal, though it may be a reflection of the notorious difficulty of establishing avian cell lines[1]

Suspensions of living HPRS Line 1 cells were examined for membrane antigens using the indirect fluorescent antibody technique[5] The specific antisera were raised in chickens against HPRS 16 infected chick kidney cells (anti-MDV), and in rabbits against suspensions of MD lymphoma cells (anti-tumour), normal thymus cells (anti-T) and normal bursa cells (anti-B) All antisera had been extensively cross absorbed The results are shown in Table 1 The anti-B and anti-T sera were specific as assessed by the staining of viable thymus or bursa lymphocytes These sera stained B and T cells respectively in the peripheral blood The anti-MDV serum was specific for virus plaques in chick kidney cell cultures The high proportion of lymphoma cells and HPRS Line 1 cells staining with the anti-tumour antiserum suggests the presence of a tumour-specific antigen, though the staining of a small number of normal lymphocytes makes the specificity of the reaction questionable The results indicate that such a tumour-specific antigen is not identical to the known virus-associated antigens Line 1 cells stained for T-surface determinants, showing smooth membrane staining with capping, typical of T cells Line 2 cells have been examined for membrane fluorescence on one occasion 100% stained for T cell determinants, and 0% for B-cell determinants The identification of the cell lines as T cells is supported by the ultrastructural studies which showed the presence of abundant ribosomes and sparse endoplasmic reticulum

Table 1 Percentage of cells showing specific membrane fluorescence*

* Mean of five determinations ± Standard error

The majority of cells in Marek's disease lymphomas are of thymus origin[5,6] The role of these cells in the histopathogenesis of the disease is not clear The lymphoid system may be involved in the production of tumours by the malignant transformation of lymphoid target cells (intrinsic mechanism), or by the participation of lymphocytes in an excessive proliferative response to new viral antigen (extrinsic mechanism)[7] Since MD usually has a multifocal origin, an extrinsic mechanism is obviously a possibility There is, however, a poor correlation between the presence of viral antigen and the site of tumour development[8] Morever, BL is also frequently multifocal and yet is a uniclonal disease, this implies that the successful development of a neoplastic clone is a relatively rare event, and may depend upon an infrequent accident of interaction between virus and cells of an appropriate transformation type[1] Tumour-specific antigens have been reported[9] in MD the results of our fluorescent antibody studies suggest that the cell lines carry membrane tumour-specific antigens The presence of MD virus in the cells parallels the role of EB virus in the proliferation of human lymphocytes *in vitro* We suggest that malignant transformation of thymus-dependent lymphocytes is necessary for the development of lymphomas in Marek's disease

reviews

Jacob as historian and biologist

The Logic of Living Systems By Francois Jacob Translated by Betty E Spillmann Pp viii+348 (Allen Lane London, 1974) £4

THIS book is a history of knowledge and ideas on reproduction and heredity It is intended by its author to be not merely a narrative account but a history which is in some sense explanatory, a history which shows how this knowledge was generated and how it changed

Jacob outlines his historiographic principles in the introductory "programme" where he rejects "reverse history"—which simply studies the succession of ideas resulting in our present views—as inadequate Rather, Jacob argues, a history of scientific knowledge and ideas must seek "to discover how objects become accessible to investigation", an "analysis of the nature of the object is required and of the attitudes of the investigators, their methods of observation and the obstacles raised by their cultural background" Using this approach, Jacob maintains, one no longer observes a linear sequence of ideas—"the confident march of progress"—each derived from its predecessors by a sort of evolutionary transformation, but instead a series of more or less self-contained and discontinuous "domains which thought tries to explore, where it seeks to establish order and attempts to construct a world of abstract relationships in harmony not only with observation and techniques but also with current practices, values and interpretations" For an object to be accessible to investigation a theory able to accommodate it must exist and "each period is characterised by a range of possibilities defined not only by the current theories and beliefs but also by the very nature of the object" This range of possibilities is the "domain", the territory within which reason can operate, and it is from these possibilities that theoretical "solutions" to problems are chosen When new theories are accepted they reorganise "the domain of the possible", modify ways of looking at things and bring to light new relationships and objects Historiographic principles of this sort, Jacob maintains, will result in a history which is concerned with "specifying the various stages of knowledge, defining the transformations and revealing the conditions which enable objects and interpretations to enter the field of the possible"

Jacob clearly has given much thought to the problems of writing history and the conceptual outline in his programme will be familiar to those who have some knowledge of that heterogeneous body of thought loosely labelled 'structuralism' His specific historiographic principles immediately bring to mind the work of Michel Foucault (and, more remotely, T S Kuhn) and it is not difficult to see the influence of Foucault's ideas on this book, even though Jacob makes no reference to him, or indeed to any contemporary historian

Jacob's careful statement of his historiographic principles and their nature led me to expect a work that would be comparable to the work of Foucault and to that of those other French students of cultural phenomena who are working within a broadly similar framework I expected a history of biology radically different from those produced within a more conventional, empirically oriented, historiographic framework, one full of new and provocative insights and interpretations I confess that I was disappointed This is a book of some distinction, certainly, it contains much of great interest, it is thought provoking, it is written in a style which is lucid and elegant and it deserves to be widely read Yet, it seems to me to fall considerably short of its stated goal, for Jacob has, in fact, produced a book which is almost a reverse history, and one that is relatively conventional, even old fashioned in some respects, especially as regards its rigorous internalism

It is not easy in a short review to do more than suggest why I found the book disappointing It is a complex work which resists easy generalisations and in what follows I am conscious that I have not done justice to it and that it requires and deserves a more detailed analysis

The book's shortcomings arise, I suspect, because of a tension or conflict between Jacob the biologist and Jacob the historian The first Jacob has made significant contributions to present knowledge and obviously has a certain commitment to it, he is concerned with the diachronic and with progress The second Jacob, in his role as historian, is concerned to do justice to his predecessors, he is interested in the synchronic but wary, perhaps, of the danger of relativism I suspect that the first Jacob had the upper hand in the writing of this book

In his discussion of the development of evolution theories, he remarks that "the role that is attributed to the past is necessarily conditioned by the way in which the present is viewed and interpreted" This remark could be applied to his own book, for in the last chapter he presents an interpretation of living systems as a hierarchical arrangement of organisations, one "enclosed" within the other like a nest of "Russian dolls", this structure provides the basis for Jacob's history which consists of a series of "stages of knowledge" in which each Russian doll is discovered Beginning in the seventeenth century with a domain of thought which is concerned with "visible structure"—the arrangements of matter, he passes to a second domain of "organisation" which occurs at the end of the eighteenth century and is concerned with the invisible unity of the organism, a unity which is later dissolved into the properties and interactions of cells, at the beginning of the twentieth century is the third domain in which chromosomes and genes are possibilities and, finally, our domain, that of the nucleic acid molecule Interposed between the discussions of the second and third stages is a chapter on "Time" in which ideas on the genesis and evolution of living things are considered

The series of historical stages which Jacob has constructed on the basis of his picture of the structure of living systems is not simply a sequence, it is a progress towards something hidden and more fundamental, it represents a journey to the metaphorical centre of the organism, a centre which for Jacob is also metaphysical, the source of order and change the genetic programme

This basic conception of progress often seems to undermine Jacob's theoretical principles He has a tendency on occasion to write with hindsight and to consider and pass judgement on past knowledge as simply a precursor of future, and therefore more fundamental, knowledge, rather than as a system possessing its own coherence Consequently, there are places where past thought is very simplified or even distorted This progressive picture also results in the omission of thought which does not fit into the pattern, the most notable example being twentieth century developmental biology

Jacob's rigorously internalist approach also seems to be in conflict with his historiographic principles and results in some disappointingly conventional interpretations Evolutionary thought, for example, is described in the programme as a product of "mid-nineteenth century thought as a whole", yet it is actually discussed in a very conventional fashion as an internal problem in biology, centring on the issue of the contingency of the living world, with a reference to similar ideas in contemporary statistical mechanics This, in my view, is neither an adequate nor a particularly illuminating account of a transformation in thought involving ideas on God, man, nature and society and their interrelations

On the other hand, problems also arise when Jacob applies his historiographic principles The notion of relatively discontinuous domains of thought results in an historical picture in which the real continuities which exist are often obscured, and one which is often too schematic His chapter on the "Visible Structure", which is concerned with seventeenth century thought, suffers as a consequence of this, even though parts of it are fascinating His belief that "mechanism, despite its limitations, represented the only attitude compatible with knowledge of that time" and that other metaphysical principles were not scientifically productive but were merely of "ethical" or "philosophical" significance, seems to me to do violence to the richness and complexity of seventeenth century thought and results in misleading discussions of, for example, the discovery of microorganisms and the circulation of the blood In these examples it seems that, although Jacob recognises that "objects" can form the subject of discourse in more than one domain, he believes that they are only accessible to investigation which is scientific and productive within a unique domain which is in "harmony" with their "nature" This presupposes that the "nature" of an "object" is completely independent of the theoretical framework in which that object is considered, a debatable assumption

The final chapter, "The Integron", is clearly written by Jacob the biologist, and contains a discussion of some current views of the organisation of living systems It is surprisingly uncritical and tends to confirm my suspicion that Jacob the biologist was the dominant personality in the writing of the whole book, for reverse or Whig history is, by and large, intended to justify the present state of affairs and to encourage us to accept it uncritically On the other hand, the sort of history in which Jacob the historian is interested, the sort which asks the question "How is it possible for anyone to believe that?", has the goal of making us ask the same question with respect to our own beliefs, and therefore, of freeing us from the spectacles of habit and from the tyranny of our own artefacts Jacob seems to be aware of this but evades coming to grips with it In the final paragraph of the book he writes "There are perhaps other possible coherences in descriptions But science is enclosed in its own explanatory system and cannot escape from it" This is to raise the possibility of freedom, and therefore the necessity of choice, and then immediately to reject it by picturing science as an autonomous and alien thing, the "Russian doll" as a Petrushka, an artefact with a life of its own It is to evade the fact that we are responsible for all our artefacts, including our "beliefs" and our "knowledge"

GERALD WEBSTER

Stimulating immunity

Chemical and Biological Basis of Adjuvants By P Jollés and A Paraf Pp viii+153 (Molecular Biology, Biochemistry and Biophysics, 13) (Springer-Verlag Berlin and New York, 1973) £7 90

AT best the subject of immunological adjuvants consisted of a potpourri of related phenomena the publication of this monograph has to some extent improved the situation

The authors have striven hard to obtain order and consistency which they achieved with respect to the chemical basis of adjuvants, although it has been done by introducing a noticeable degree of repetition I found the earlier chapters especially informative with regard to the adjuvant materials of mycobacterial origin In the area of cellular immunology, Jollés and Paraf have not achieved such clarity and there is no coherent discussion of immunopotentiation by substances acting on populations of differentiating cells

I found the last chapter on the practical uses of adjuvants very incomplete and nothing like as scholarly as the earlier chapters It would have been useful to have had a more critical and detailed discussion of recent French work where certain bacterial vaccines (*C parvum*, BCG) have been used in the treatment of leukaemias Direct toxicity is an important consideration and is adequately discussed, however only brief mention is made of the danger of adjuvants stimulating unwanted responses to autoantigens

The book is well produced, and I noted few typographical errors Its usefulness might have been increased if the bibliography had been made to serve additionally as an author index, simply by adding the page numbers of each citation after each listed reference 'Adjuvant workers' should find this monograph worth buying

D W DRESSER

Natives of Canada

Athapaskan Adaptations By James W Vanstone Pp x+145 (Worlds of Man Cultural Ecology Series) (Aldine Chicago, April 1974) $7 50 cloth, $2 50 paper

THE Athapaskan speaking peoples occupy a vast forest region of northwest Canada and most of the land surface of Alaska As Walter Goldschmidt the series editor suggests in the foreword, Athapaskan culture was less dramatic than the Northwest Coast or the Plains types, but no less adaptive, "a cultural flexibility, a quiet competence, a sustained ability to blend in with local environment" (page vii) The Athapaskan groups are seen as small communities of hunters and fishermen adapted to salmon fishing in the Pacific drainage lowlands, collective caribou hunts in the open northern regions, and more solitary moose hunting in the dense forested southern regions of Great Slave Lake

The book is an attempt to present a very generalised account of the ecology and social organisation of the Athapaskan groups at the time of contact with European and Russian entrepreneurs about 1750 AD It is based on the current research of many scholars in the field, as well as those of the 1950s and the 1920s In addition there are two principal sources from the early period, namely Samuel Hearne's account of his trip to the Coppermine River, NWT Canada of 1769–72 and Henry Allen's to the Ahtna of the Copper River, Alaska in 1885

The linguistic units were divided into small, mobile task forces of hunters and fishermen, often widely separated if not isolated Economic variations from this pattern were minor But the author demonstrates an unaccountable variation of social practice Among the 'Northern Athapaskan' some units have hereditary leadership, others have none There is bilateral descent in some while others have matrilineal sibs, some have group and some have individual ceremonies There is both matrilocal and flexible residence patterns, and a modified male vision quest is present in some

Abandonment of the aged is present in most, but one region recognises special high status for the aged. Even the potlatch is present in some regions. Perhaps most significant is the range of marriage regulations, all the way from parallel cousin through cross-cousin to no-cousin marriages.

The picture of the Athapaskan before outside contact is obscured by the fundamental changes wrought by two hundred years of the fur trade, and one hundred years of Christian mission activities. Since the end of the Second World War, education, health facilities and police administration have resulted in the development of larger population centres, the construction of many buildings, and the presence of alien supervisors in both Canada and Alaska.

The author describes in detail the settlement of Old Crow in the Yukon which exemplifies this recent change. He suggests "the community members almost never join in any work for the community as a whole because there are no leaders who can organise activity for the general welfare and improvement of the settlements" (page 117). Thus the members of Old Crow "have not been successful in developing social mechanisms to cope with the problem of living in large, permanent settlements" (*ibid.*). Although this is a general phenomenon throughout northern Canada, the author indicates the cause of failure is that "traditional social organisation emphasised the freedom of the individual family and the authority of the family head" (page 118).

Surely to seek causes in traditional culture forms is an oversimplification at best. Rather, the large permanent settlements based on imported funding and direct administration by aliens have emasculated the indigenous people. Most of Canada's indigenous peoples are in a similar position to these at Old Crow and are equally politically inarticulate. Many observers feel that the only change possible will be through the new regional organisations of Indians, Metis and Inuit (Eskimos). Dr Vanstone's views on their organised protests and negotiations with governments would have been valuable.

R. W. Dunning

Structure of the cerebellum

Cerebellar Cortex: Cytology and Organisation. By Sanford L. Palay and Victoria Chan-Palay. Pp. xii+348. (Springer-Verlag: Berlin and New York, 1974.) DM156; $64.

For the neuroanatomists of the nineteenth century, the cerebellum was a source of fascination, providing an unending series of vexing problems and forming the battle ground between the neuronists, who believed that each nerve cell was a discrete entity, and the reticularists who argued that all the nerve cells in the brain were fused together into one extensive network. The reasons for the fascination and the conflict become quickly apparent to any reader of this superb book; six types of neurone, including the largest and the smallest types in the central nervous system, regularly interconnect to process the inputs conveyed by the two main afferent fibre systems. Furthermore, the modes of terminal arborisation of the fibres in the cerebellum exemplify both the simplest and the most complex types found in the nervous system.

During the latter part of the last century, the various cell types of the cerebellum were quickly recognised and, with the new staining technique, their processes were gradually characterised. All the great neuroanatomists of the past contributed to this achievement but it was Ramón y Cajal who in 1888 gave precise descriptions of all six cell types, as well as the 'climbing' and 'mossy' fibres, which form the two input pathways. But there remained a host of important questions which could not begin to be answered until the electron microscope had been developed.

This book takes up the problems Ramón y Cajal left unanswered. Starting from the Purkinje cell, the authors describe in successive chapters all the remaining cell types and afferent fibres. Each chapter begins with a brief historical account of the discovery and ensuing controversies, together with an assessment of the original descriptions. Then the up-to-date knowledge is lucidy presented. The book may be read at various levels. For the uninitiated camera lucida drawings of different neurone types and electron micrographs accompanied by detailed expositions of ultrastructural features will provide a glimpse of the basic 'wiring diagram', and of its extraordinary intricacy. For neuroscientists, it will be an invaluable source book. It provides a comprehensive overview of the important facts unravelled in the past two decades. These include evidence derived from both the optical and electron microscopes, as well as the electrophysiological techniques. In addition, numerous details of previously unpublished observations of the authors are incorporated.

This book is a credit to its senior author, whose sustained interest and imaginative application of current techniques have brought about a significant advancement in our understanding of the structure of the cerebellum. It is a worthy successor to the classic works of the Ramón y Cajal era.

Shin-Ho Chung

Uncontrolled eddies

The Analysis of Eddy Currents. By Richard L. Stoll. Pp. xii+128. (Monographs in Electrical and Electrical Engineering.) (Clarendon: Oxford; Oxford University: London, January 1974.) £3.50.

Despite the crucial importance of eddy current phenomena, in devices like the induction motor, the undergraduate introduction to the subject is necessarily very limited. It depends largely on equivalent circuit concepts, and assumes that the eddy currents are confined to insulated conductors, and are under the control of the designer. Recent developments in large, electrical machines and electromagnetic devices have added to the range of problems in which the eddy current flow paths are not so clearly defined or controlled, and have provided a fresh impetus to their study. In general, the problems demand a direct solution of the underlying field equations, yet even the simple methods and solutions receive scant attention in most textbooks on electromagnetic fields, and descriptions of more recent work are confined to the original references. Dr Stoll's book fills an important gap. It combines in a condensed and convenient form a description of basic analytical methods, and an introduction to numerical techniques by which the more complex problems, including flux and current penetration into iron, can be solved by computer. It is an essential addition to the bookshelf of those faced with the need to analyse eddy current problems, particularly at low (that is power) frequencies.

Dr Stoll writes as a specialist who has made considerable contributions to his subject, and he has included a great deal of useful material in 125 pages. Yet his treatment is admirably lucid, and the relevant parts of the book are well suited to the needs of electrical engineering and physics undergraduates and others seeking an introduction. The description of numerical methods is necessarily selective, in an area which is rapidly developing, and although it is a pity that topics such as finite-element and integral methods have had to be referred to only briefly, the material is well chosen for those whose principal interest is in applying the methods, rather than developing them. The book meets admirably its intended purpose, which is to provide an understanding of the more important methods and a bridge to specialist literature. It is well produced, and is a pleasure to read, although at some points a less condensed treatment, with additional diagrams, might be helpful to students with only a limited familiarity with electromagnetic field equations.

C. J. Carpenter

Mechanisms in minds

Current Biochemical Approaches to Learning and Memory. Edited by Walter B. Essman and Shinshu Nakajima. Pp. ix+205. (Monographs in Modern Neurobiology.) (Spectrum: Flushing, New York; distributed by Halsted (Wiley), March 1974.) £8.40.

This book consists of an introductory chapter by the two editors, and eight chapters devoted to current research in the area of biochemistry and learning. The first chapter is a short, readable and sensible historical review, and the only chapter for which there would seem to be any excuse for publication. The remaining chapters are brief, superficial, badly written, and poorly edited; mistakes in spelling and punctuation, and peculiarities of grammar are common throughout, particularly in those chapters by authors whose first language is, as is all too evident, not English. There is not even any consistency in the way in which references are set out, some authors giving titles of papers, and others, page numbers only.

The brevity of the chapters has two unfortunate effects; first, no attempt is made to place the research described in a wider setting, by showing its relationship to the often very large body of relevant material from other laboratories. Bogoch, for example has a reference list of 29 entries, 28 of which are to his own work; Tsukada has one reference (to Tsukada). In some cases, there is a distinct impression that the authors are simply unaware of the research carried out in other laboratories—the chapter by Ilyutchenok and his colleagues on cholinergic mechanisms does not refer at all to Carlton, and only in passing to Deutsch.

The other consequence of brevity is that the evidence in support of authors' claims is very rarely presented in sufficient detail to allow its evaluation, and frequently no very clear idea emerges of exactly what procedures were used. What little hard evidence is provided is distinctly discouraging, displaying as it does, in almost every chapter, a cavalier attitude to statistics. For example, Fjerdingstad, in the only chapter on transfer of learning, applies one-tailed *U* tests to each of several test sessions on the same animals, without any regard to the fact that acceptable significance levels change drastically with such a technique. Whether such considerations would influence the editors is open to doubt. Nakajima in his chapter reports an experiment, with six groups of eight animals each; although he first states that the number of animals is insufficient for statistical analysis, he nevertheless goes on to tell us that the results "suggest" one conclusion and "also indicate" another.

In short, this is a book that should never have been published. It is extremely expensive, and one can only hope that few institutions, and fewer individuals, will feel obliged to purchase it.

Euan M. Macphail

Plants in action

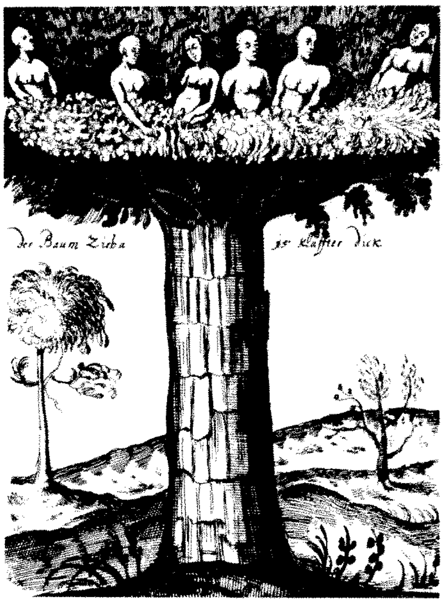
Dynamic Aspects of Plant Ultrastructure. Edited by A. W. Robards. Pp. xii+546. (European Plant Biology Series.) (McGraw-Hill: London and New York, June 1974.) £8.95.

Dr Robards has brought together seventeen distinguished workers to write fifteen chapters in his symposium. It is difficult to fault either the credentials or the international flavour of the chosen authors. The advantage of the symposial approach is that each section can be written at the front of knowledge of that topic and, given a firm editor which has here been achieved, a relative evenness of treatment is possible. My quarrels with statements made by individual authors are of the level to be settled at small conferences and not of major substance. The disadvantage of the symposial approach is that each author is constrained to write within a precise framework and this inhibits cross correlations or interpretative sections on, for example, overall control mechanisms or communication between cells. A book of this type, excellent as it is, must therefore be read in conjunction with single-author works at the same level.

Errors are few and good references numerous. Economies such as the lack of line 'justification' are justified and bother me not at all. But was it worth putting in some, only just relevant, expensive colour plates and printing all the rest of the plates on muddy matt paper even muddier than Dr Robards's previous text in this series? It does hold the price down to a reasonable level, but it must have enraged the authors of some of the beautiful micrographs included.

B. E. Juniper

Erotic tree



The Zieba tree, described in 1676 by Christopher Vielheuern. From *Bizarre Plants: Magical, Monstrous, Mythical* by William A. Emboden. Pp. ix+214. (Studio Vista, London, 1974.) £2.95.

Techniques for analysis

Analytical Chemistry: An Introduction. By Donald J. Pietrzyk and Clyde W. Frank. Pp. xx+667. (Academic: New York and London, April 1974.) $13.95; £6.70.

The course described in this book was originally designed as a one-semester introductory course in analytical chemistry for subsidiary students, but it is now intended for students taking chemistry as their major subject. There are four main areas: spectroscopy, acid-base methods, potentiometry with special reference to ion selective electrodes and chromatography. These topics are subdivided into further parts.

Analytical chemistry now covers such a broad area that only in specialised courses can it be treated in depth. An introductory course should set out to show what techniques are available and provide some guidance as to which are suitable for a particular purpose. Generally, in an introductory course the main limitation is time and therefore a very careful selection has to be made.

The authors of this book have obviously given a great deal of thought to the problem, for this is a well balanced course presenting information on all the basic methods and techniques of analytical chemistry. A balanced picture of the respective parts played by instrumental and classical analysis is also provided.

Some excellent exercises are described and possibly the only criticism to be made here is the omission of one on solvent extraction; it is a curious fact that most teaching texts on analytical chemistry avoid this exercise, despite the importance of the subject. Another criticism is that a better selection of redox indicators might have been provided; the quoted potentials of some are incorrect.

These are very minor shortcomings and in general this is an admirable and well thought out text which all teachers of analytical chemistry should find of great value.

R. Belcher

See-through women replace yellow-bellied sapsuckers

Boston's Museum of Science Open daily Adults $2, children $1 Closed Thanksgiving, Christmas, New Year, July 4, Labour Day

THE Museum of Science in Boston lives in one of those bleak, deserted areas peculiar to American cities Although a mere five minutes' walk from the city centre the pedestrian finds himself hideously outnumbered by speeding cars On a causeway across the Charles River, the buildings tempt you in by their very humanity amidst the heartlessness, and (again an American feature) an affluent and joyful interior in stark contrast to the external world For the museum, whatever else it is, is full of joy, and the most un-museum like museum I have yet seen

One colossal advantage it has over many other museums is its youth When Bradford Washburn became director in 1939 it was sited in a four-square civil-war vintage building in downtown Boston, and as with so many museums of science, it was hard pressed for space and dominated by natural history exhibits Washburn, a distinguished explorer and mountaineer, returned after war service to create a completely new multidisciplinary museum that would be particularly attractive to the young In many ways he was lucky The forties and early fifties were times when it was probably easier than today to persuade donors that science needed good publicity Harvard Museum of Comparative Zoology, furthermore, served as a reference museum, releasing him from the burden of endless display cases of stuffed animals The closeness of many educational, medical and technological institutions ensured ready assistance and advice (though is this true in London, say?) And there is Boston—just the right sort of city to plant this sort of thing in

But if he was lucky, he has also had an incredible flair for what appeals to the young, and above all what makes them feel at home As part of my preliminary research I took a couple of young boys—5 and 3—and let them loose They found a lot that they enjoyed—a surprisingly large fraction of the exhibits—but eventually they gravitated to a huge tyre hanging, playground-style, from a ceiling This gave them twenty minutes of simple fun, with them happily parked therein (indeed eventually almost impossible to prise out) I could look around at leisure The next day, when I met Ned Pearce, the Museum's librarian, he had marked on a map for me what the most popular exhibits were—an uncannily accurate description of Wilson's and Philip's somewhat erratic route through the museum And the giant tyre? Yes that was on the list and Mr Pearce was mildly defensive about it, thinking I as a high priest of scientific orthodoxy would be cynical about a mere plaything "You see we regard it as an important exhibit—children learn that there are things they can climb on here and not get screamed at One of our key roles is to persuade kids that this a friendly place and that people here are nice " This is put somewhat more sentimentally in one of their glossy brochures as "When [children] arrive they are not only met by wonder and excitement and discovery They are also met by love " Mawkish stuff maybe but there is more than a grain of truth in it A substantial fraction of the three quarters of a million visitors each year come in school buses many of these from the inner city They are naturally hostile to anything that smacks of authority and schoolroom formality, and for them a large number of volunteer guides—adults or teenagers—are laid on It is essential, says Pearce, that guides, whether volunteer or full-time, should not be seen as policemen

There has been much discussion in the museum on the social aspects of the educational programmes that they run, which include Saturday morning classes Is the museum seen as a middle class institution perpetuating science as a middle class occupation? Questions like this (barely asked at all in England) are put in sharp focus when a busload of inner-city poor debouches into the arms of a potentially loving phalanx of suburban moms with their biology degrees and their worthy aims As far as possible the museum tries to recruit volunteers and guides who can relate at first hand with the underprivileged but it is a difficult task Already they are phasing out some of the Saturday activities which have tended to become high quality baby-sitting for the middle classes

Once inside, how does the youngster experience the "enjoyment of learning" that Washburn dedicates the museum to? I think he does it in two ways—through the imaginative use of space, and through unashamed compromise As museums go it has a very average amount of square footage per visitor But there seemed to be less clutter and less pressure to circulate Come on a rainy Sunday, said Pearce, then you'll see things differently, but I think the point is that if you go on a sunny Wednesday you can really breathe

And the compromise—it's not a poor man's university You can mingle with a full sized *Tyrannosaurus rex* but the next exhibit along is a giant magnet one way, and a telephone exchange the other The hot air balloon (for my money the best exhibit) rubs shoulders with the deep diving submarine There is no logical order or historical succession to it all, it is a huge sampler Washburn says "To touch a snake, to see liquid air or to pat a porcupine are never-to-be-forgotten experiences which will launch a youngster into a science career a thousand times more rapidly and powerfully than any number of carefully labelled exhibits"

In twenty years how has fashion changed in Boston? Natural history was and is unassailably Number One at all ages, declares Washburn But whereas the prime interest used to be birds it is now 'me' the human being and how it works Certainly the transparent woman, the stages in childbearing, the heart and the appendectomy draw more than such commonplaces of the seventies as lunar modules and computers, though the number who stay the course of ten realistic stages of removing an appendix without retiring slightly queasy is small

The museum runs on an annual budget of around $2 million of which about half is collected through admissions (including state-paid visits of schoolchildren) and memberships Private and corporate donors find the rest Of course there is debate about the admission charge, although the staff fear for the crush on Sundays were entrance to be free But at present that cannot even be considered

Washburn has been successful at persuading the corporate donors to pay without visible returns The museum is mercifully free of brand name exhibits which elsewhere range from the excellent, such as the IBM mathematics pavilion at Chicago, through the blatantly commercial "would you mind stepping into our exhibit and answering a five minute questionnaire on your cooked-ham eating habits?" also at Chicago to the dreary cutaway models of factories made by the apprentices and presented by the managing directors at—well, never mind where

As long as Brad Washburn and his staff can continue to say 'no' if it isn't fun, I suspect that Boston will continue to be a hotbed of bright young scientists, many of whom will have experienced their first awakenings in or near the giant tyre DAVID DAVIES

obituary

Léon Rosenfeld

LÉON ROSENFELD was born at Charleroi, Belgium, on August 14, 1904 He studied physics and mathematics at the Université de Liège where he obtained a D Sc in 1926 He was associated with L de Broglie and P Langevin in Paris (1926–27) with M Born in Gottingen (1927–29) and with W Pauli in Zurich (1929–30) During this period he also collaborated with Th De Donder in Brussels In 1930 Rosenfeld visited Copenhagen, where he began a collaboration with Niels Bohr which lasted until Bohr's death in 1962 Rosenfeld joined the Université de Liège in 1930 From 1940 to 1947 he was Professor at the University of Utrecht and from 1947 to 1958 at the University of Manchester In 1958 Rosenfeld became a professor at NORDITA

Léon Rosenfeld was a member of the Royal Danish Academy, the Académie Royale de Belgique, the Académie Internationale d'Histoire des Sciences and the Académie Internationale de Philosophie des Sciences He received the Prix Francqui, a high Belgian distinction, in Brussels in 1949

The scientific interests of Léon Rosenfeld were unusually wide They included quantum electrodynamics, nuclear physics, statistical mechanics, epistemology and history of sciences His monographs *Nuclear Forces* (1948) and *Theory of Electrons* (1959) had a wide circulation

His best known contribution is probably his fundamental paper with Niels Bohr in 1933 on the measurability of electromagnetic quantities In this paper Bohr and Rosenfeld showed that the only meaningful statements of quantum theory when applied to electrodynamics concern averages of field components over finite space time regions In this way they proved the logical consistency of quantum electrodynamics

Another series of well-known papers by Rosenfeld, mostly in collaboration with Humblet from Liège, concerns the theory of nuclear reactions (1962–65) These papers introduced a new and precise definition of resonant states

All his life Rosenfeld was deeply interested in the foundations of physics The 'Copenhagen' interpretation of quantum mechanics, still accepted by the majority of physicists, was developed by Bohr and Rosenfeld following the pioneering work of Heisenberg, Born and Bohr

After Bohr's death Rosenfeld appeared as his natural spiritual heir It would be a mistake, however, to consider Rosenfeld as simply the guardian of the Copenhagen orthodoxy More than anyone else he knew that one of the main objects of theoretical physics is to define the precise domain of validity of concepts involved in the mathematical models of physical reality He wrote, "No physical concept is sufficiently defined without the knowledge of its domain of validity" For this reason he devoted most of his efforts during the last years of his life to showing that the coherence of the rules of quantum mechanics can be tested explicitly through the study of the dynamics of large systems For him the foundations of quantum mechanics had not to be looked for in some axiomatic formulation valid for small systems with a discrete spectrum energy but, on the contrary, in the study of the limiting procedures involved in going to large systems Since his early work he emphasised that there should exist a new type of complementarity between the "irreversible character of the macroscopic behaviour of the large systems and the time reversal invariance of its dynamical description at the atomic level" The outcome of these considerations is a generalised transformation theory which he developed in close collaboration with Prigogine's group in Brussels and in Austin This transformation theory makes it possible to go from the usual representation of dynamics in terms of the Liouville–von Neumann operator *L* to a new representation in which the contributions responsible for irreversible processes are explicitly displayed

His fatal illness brutally interrupted his contribution to the promising new development in theoretical physics

For Rosenfeld science was a total engagement Far from being a simple intellectual curiosity, Rosenfeld, like Bohr, "conceived science as a human endeavour to achieve harmony with nature, a common task to which it was the earnest duty of each individual scientist to contribute his share"

Rosenfeld will be remembered and missed by all his friends and scientific collaborators who had the privilege of knowing him and of appreciating his exceptional personal, moral and intellectual qualities

---

Announcements

Appointments

M. A. Sleigh has been appointed to the chair of biology at the **University of Southampton** (corrected announcement)

K. C. Calman has been appointed the Cancer Research Campaign Professor of Oncology at the **University of Glasgow.**

International meetings

September 10–11, **Energy Conservation Conference,** Glasgow (National Engineering Laboratory, East Kilbride, Glasgow G75 0QU)

September 23–26, **International Symposium on Contamination Control,** London (The Sam Black Organisation Ltd, 4 Harmsworth Way, London N20 8JU)

September 24, **Symposium on Human and Veterinary Trematode Infections,** London (Dr A B Simmonds, Chelsea College, Manresa Road, London SW3)

October 1–3, **1st National Topical Meeting on Nuclear Process Heat Applications,** New Mexico (Robert Y Porton, Public Relations Office, Los Alamos Scientific Laboratory, PO Box 1663, Los Alamos, New Mexico 87544)

October 21, **Chemical and Mechanical Energy—Utilisation in Agriculture** (Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London SW1X 8PS)

Erratum

In the article "Ionisation ledges in the equatorial ionosphere" by R Raghavarao and M R Sivaraman (*Nature*, **249**, 331, 1974) the first sentence of the third paragraph should read, The cusps were observed on ISIS–2 ionograms from the dip latitude region 9°N to 7 5°S recorded at Ahmedabad on October 6, 1972

The reference number for equation (1) should be 5 instead of 4

nature

Can, or should, the swing be stopped?

A MONTH ago we looked at the way that student preferences were changing in Cambridge Now the Universities Central Council on Admissions has released a comprehensive statistical analysis of students' applications and admissions for all universities of the United Kingdom (Statistical Supplement to the Eleventh Report, £1 25) The figures apply to the year of admission 1973—it is some disappointment that it takes almost a year to produce a document of such importance—but the sections of most interest deal with trends since 1969

Many of the figures are rock-stable from year to year In 1969 11 6% of applicants came from the North West, in 1973 11 3%, 33% from the South East in 1969, 33 7% in 1973, and so on The percentage accepted is uniformly 51% both in space and time The only deviation seems to be Scotland which apparently can only get 40% of its applicant sons and daughters into universities But then your instinct says that surely the Scots do not seem any more stupid than the rest, further hunting reveals that 'three Scottish universities are partly outwith the UCCA scheme' and your dictionary tells you what that word means and that it is of Scottish origin

The middle classes, less than 30% of the population, provide almost three quarters of the candidates—and working class applicants have declined from 29% to 26% in five years, although they do now fare marginally better in getting accepted

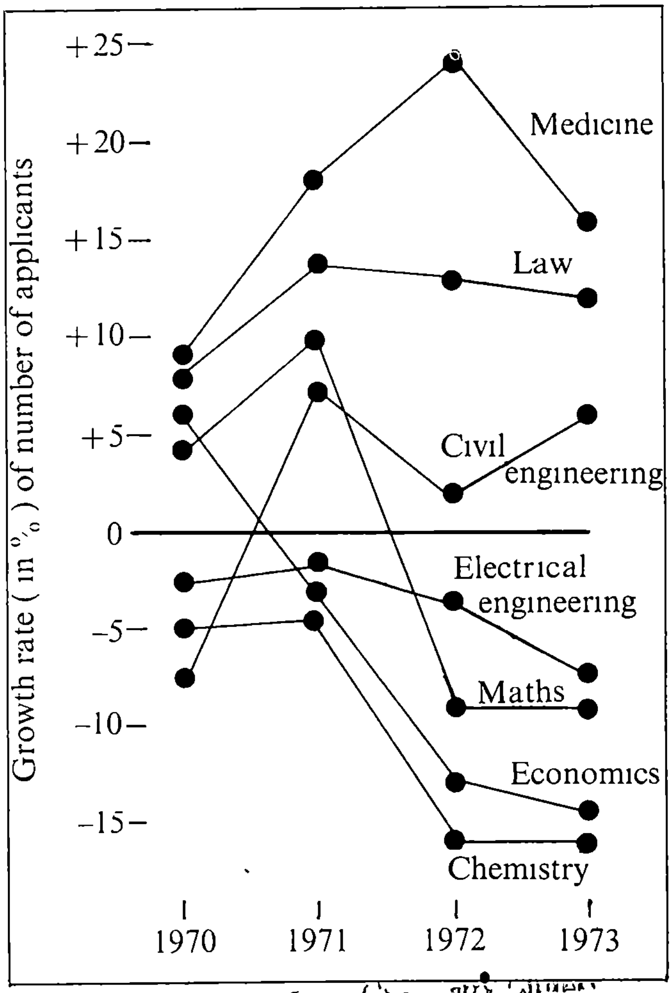
Whilst all these trends are slow or negligible, one trend has been dramatic the swing away from science In the figure we show the way in which fashions have been moving in seven subjects which have large enrolments at university For instance, a value of +10% for mathematics for 1971 means that there were 10% more applicants for entry in 1971 than in 1970 who gave mathematics as their preferred subject Some other subjects not shown here have comparable trends, physics and mathematics follow similar patterns, so do mechanical and electrical engineering Geography, English and History are relatively static Social, administrative and business studies follow strange ups and downs but have shown no long term trend

In terms of absolute numbers, there were 7,000 applicants for medicine in 1969, almost 13,000 in 1973, 5,000 for law in 1969, almost 8,000 by 1973 Chemistry on the other hand had slumped from 3,700 to 2,400 Less than one in four of those applying in 1973 to do medicine were admitted, whilst two thirds of those applying for physics or chemistry were accepted What is more a substantial fraction were admitted to physics or chemistry who had not even listed it as first choice

It used to be said disparagingly of medical students that they were only in medicine because they found physics and chemistry too difficult, but figures in the UCCA compilation show that the increased selectivity now possible has made the entering medical undergraduate the best academically qualified of any

Everyone will have his own explanations of these trends, but two things need careful underlining The dramatic transition from the 1971 to the 1972 entry was no flash in the pan since the 1973 growth rates are closely similar to those of 1972 If science applications were depressed in 1972 by gloomy job prospects (up to six or seven years in the future!) and disenchantment with technology's environmental record, then to keep the growth rate so negative for yet another year would have required even more gloom and disenchantment.

Second, it is insufficient simply to acknowledge the falling off in science applicants, say yes it was bound to happen some time, hold a meeting or two and hope that the problem resolves itself somehow The diversity of opinions expressed at the British Association last week (page 91)—good prospects in engineering, bad in biology cannot but confuse the school-leaver The message from school science teachers is that there is no turnaround in recruitment to science in the immediate future. Can the country, can science afford to lose out in this way? The answer is not automatically that it can't, and it would be foolish blindly to assert that the number of scientists must always grow Nevertheless at present the size of the annual intake is controlled by forces which are so remote from job prospects four to seven years hence that a market place type of situation could hardly be said to exist Eventually the community must come to grips with the question of how it wants its future size determined



[illegible]

Ominous news for marine science

The Law of the Sea Conference is over and the way in which marine scientific research is to be organised and controlled is not yet agreed

CARACAS—the site of the Third United Nations Conference on the Law of the Sea—a booming, noisy city, set amidst the green hills of the national park area Ten weeks of slow and protracted discussions in three main committees, each open to delegates from all the 137 countries attending, plus numerous intergovernmental and nongovernmental bodies of all sizes, composition and pursuasion Superb arrangements laid on by the Venezuelan Organising Committee, together with the United Nations Secretariat (at considerable cost) though a number of nations (particularly in Africa and Asia) expressed concern at the communication difficulties they have encountered and expressed their need to keep in close touch with their governments, particularly during the later negotiating stages of the conference Chiefly for this reason it was decided to hold the next session in Europe

Almost unanimous agreement that further sessions should not exceed six or seven weeks in length as humans get tired and stale if they attempt to confer for a longer period and little is achieved in the extra weeks Winter troglodytes from northern latitudes trying to avoid another summer session —we have not had an opportunity to see our families in the sun for six years, smaller and less well off countries trying to reduce the length of future sessions, owing to the high cost of keeping large delegations abroad—countries have now had the opportunity to define their positions, let us get on with the negotiating and this will only happen during the final session, other countries talking about two sessions in 1975 and at least one in 1976

Countries with differing views on the importance of the whole exercise—some suggesting that this was the most important conference that has ever taken place on the earth, and that we were trying to save civilization, others wondering whether the conference had the slightest relevance to the future of the human race, and still others believing sincerely that it was doing positive harm to the aspirations of the less developed countries

Sharp disagreements within delegations, usually ending up with victory for military and economic interests over those of the marine scientists and environmentalists Different types of disagreement between marine scientists —one faction claiming that freedom of scientific research in the oceans is essential for the future of scientific research as a whole, and that the restrictions proposed would either kill marine science dead or make it an undercover activity which no individual state or international authority could hope to prevent, or the opposing view—that developed countries have got to realise that the days of 'Challenger' type expeditions at the expense of the natives are over, and it is now the turn of the developing countries

These may be negotiating positions, of course, and doubtless if the declaration made by the President and endorsed by the conference on June 27, is to have any effect, the extreme views will disappear in the interests of gaining concessions elsewhere This declaration reads

"Bearing in mind that the problems of ocean space are closely interrelated and need to be considered as a whole, and the desirability of adopting a Convention on the Law of the Sea which will secure the widest possible acceptance, the conference should make every effort to reach agreement on substantive matters by way of consensus and there should be no voting on such matters until all efforts at consensus have been exhausted "

This consideration is in fact vital when it is remembered that the first UN Conference on the Law of the Sea, Geneva, 1958, which produced four international conventions, has received relatively poor support from states These were the Convention on the Territorial Sea and Contiguous Zone (46 states parties, in force since 1964), the Convention on the High Seas (54 states parties, in force since 1962), the Convention on Fishing and Conservation of the Living Resources of the High Seas (35 states parties, in force since 1966), the Convention on the Continental Shelf (53 states parties, in force since 1962) Furthermore, the second UN Conference on the Law of the Sea, Geneva, 1960, failed in its attempt to resolve disagreements over the breadth of the territorial sea and fishery limits

The three main committees inherited the work of the UN Committee on the Peaceful Uses of the Sea-Bed and the Ocean Floor beyond the Limits of National Jurisdiction and it is on the lengthy deliberations of that committee over a period of five years that the present discussions are based and the texts of the convention articles will be developed

It is becoming clear now that the final agreement will most likely include a territorial sea twelve miles in width, an economic zone beyond the territorial sea (referred to by the Latin Americans as the 'patrimonial sea') and an international zone covering the deep sea-bed, the water column being high seas The general trend embodying several proposals is that countries where the width of the shelf is less than 200 miles, will have an economic zone of 200 miles covering both the shelf and the water column, others, where the shelf extends to over 200 miles, will have an economic zone of 200 miles and in addition sovereignty over the sea-bed out to the edge of the continental rise (this additional sovereignty will not include the water column) The fact that this limit is unidentifiable in most parts of the world because of the lack of data or lack of rise, has so far been conveniently ignored

Among the more controversial matters on which as yet no agreement is in sight, are the extent of coastal state jurisdiction in the economic zone with regard to such matters as pollution control, scientific research, exploitation of living resources, and the degree of control to be exercised by the international authority over the international sea-bed area—this varies from the "none" of the states most physically capable of working in this area to the vesting of exclusive and direct control of all exploration and exploitation in the International Authority A serious draft article "Right to undertake Marine Scientific Research", at present on the record, states "Marine scientific research in the international area shall be conducted directly by the international authority and, if appropriate, by persons, juridical or physical, through service contracts or associations or through any other such means as the International Authority may determine, which shall ensure its direct and effective control at all times over such research"

The fear of scientific research shown by many of the developing countries is based on two factors, one real and one controversial The former is the military bogey, the possibility that a ship operating off the coast of another state may be gathering data inimical to the coastal state, in addition to its declared programme (and not necessarily oceanographic data, for example the

Pueblo episode has been invoked on more than one occasion). In fact this is a case of the past behaviour of certain countries with regard to the release of oceanographic data coming home to roost. The theory behind the present World Data Centre system is that each country by injecting its data into the system qualifies to extract all data sent in by other countries. In fact a number of countries are notorious in that they participate in the system but, caught by military classification of data, they submit a minimum of their own, at the same time however calling loudly for complete submission of all data by others. This is particularly true of water temperature and to a lesser extent salinity data, of use to the military for acoustic detection of submarines. Marine pollution data, being of little military value, escapes the military clampdown.

The counter arguments deployed are that no convention or international regime is going to stop this type of behaviour. The navies of the world will continue with this policy until submarines or sonar become obsolete and it is the marine scientists wishing to work on other pressing problems who suffer.

The second fear is economic and is based on the premise that knowledge is power—in some unexplained way knowledge of the sea or sea-bed gained by a country carrying out scientific research, can be used to its economic advantage at the expense of the coastal state. In fact the coastal state desperately needs such knowledge if it is to benefit from any worthwhile exploitation of the area over which it has rights, and illegal exploitation which is a much slower process, will be far easier to prevent, particularly if the International Authority were developed to this end and the world's navies, which after all are the only possible forces that can police these areas, are mobilised in support.

At the present, the International Authority is seen by many countries as a panacea for all ills. There has been complete lack of consideration given to the way in which the authority will carry out its terms of reference and the structure it will need for this purpose, that is, how it will assess research projects submitted to it, whom it will recruit to carry out this task, what they will be looking for anyway. In theory, the authority will have to study each project submitted to it and to decide that the declared objective or purpose of the research is as stated, that it is not to the detriment of any coastal state (if in waters over which it has right) and that other criteria are laid down are being adhered to.

To undertake a task of this nature, a very large staff of highly qualified marine scientists of many disciplines would be needed and it is quite clear that inherent delays in obtaining consent would be enormous. At the same time that the developing countries are asking for the international authority to take on this vast and sophisticated task, they are clamouring for a transfer of technology, by which is meant an expanded training and education programme to build up their national marine science infrastructures. This latter exercise is fully justified but could well be killed by the former. But in any event very little detailed or serious consideration has been given to this subject and the conference has before it only one very general proposal dealing with the matter.

The basic world shortage of marine scientists in all but a few countries has led to a considerable reluctance by the United Nations and its specialised agencies to recruit top people in this field from the developing countries, as this usually results in an immediate weakening of the marine science infrastructures in the countries concerned; almost certainly these have been painstakingly built up over a number of years.

"It is a sad reflection on our times that . . . most delegations present consisted of lawyers and politicians, with little or no scientific support"

The staff, for a viable international authority capable of carrying out the assessment tasks proposed for it, would have to be obtained either from the very developed countries whose activities the authority has been set up to restrain or if, as is more likely, the United Nations staff quota system is used, largely from the developing countries; the latter arrangement would spell disaster to the marine aspirations of many of those countries.

There is also a real fear that the international authority will become yet another United Nations agency, to be paid for by the developed countries, that is, those countries whose activities will be most heavily constrained, with a complete lack of internal policy except to increase its empire and to become operational at the expense of other bodies which have been working in the same field, often for many years. Existing United Nations bodies already have a good if inadequate record of activity in this field; the Intergovernmental Oceanographic Commission of Unesco, for instance, already offers its member states an independent assessment facility for any project in which there is cause for dispute between a coastal state and a state wishing to carry out scientific research in waters over which the coastal state claims jurisdiction.

A fruitless exercise at present being carried out by certain of the developed countries, is an attempt to legislate separately for pure and applied research, as if these are rigidly definable activities. Certainly there is a white area of pure marine scientific research such as investigation of the history of the earth and the theory of plate tectonics; certainly there is a black area of applied research such as development of seismic survey methods to detect salt domes capping oil reservoirs, thus providing an indication to the oil companies of the most likely positions in which to drill to obtain a strike; but in between, there is a great grey area having both pure and applied connotations inextricably mixed, and anyway there is very little pure research that does not have an applied fallout of some kind. Besides this, such legislation would do considerable harm to applied research and survey work, needed by both developed and developing countries alike if the ocean resources are to be exploited economically for the benefit of mankind.

An unfortunate trend that has evolved during the Sea-bed Committee and conference sessions, has been the apparently successful attempt to lump all sorts of diverse data collecting activities under the heading of scientific research, which of course they are not and never have been; these include meteorological, oceanographic and bathymetric data gathering for such purposes as weather forecasting, compilation of navigational charts and so on. For instance, if a country wishes to place automated transmitting buoy systems (known as ocean data acquisition systems, aids and devices, or 'ODAS') off the coast to report the approach of hurricane force winds, this is now known as scientific research.

It is essential that such activities should be seen in their true perspective as ocean services—activities for the compilation of products for the benefit of developed and developing countries alike. Restrictions on data collection and exchange can help no one and do harm to many.

It is a sad reflection on our times that although, as pointed out by the Secretary of the Intergovernmental Oceanographic Commission to Commitee III, a basic knowledge of the oceans—what they are, how they behave, what they consist of, and so on —is essential to the success of the conference and the subsequent convention, yet most delegations present consisted of lawyers and politicians, with little or no scientific support. ☐

international news

The British Association at Stirling

THIS year's summer meeting of the British Association (BA) in Stirling, four days of lectures devoted to science ranging in purity from the geology of Scotland to witchcraft, was deemed a great success by its retiring President, Sir John Kendrew. More than 2,000 members attended this unique forum, the best attendance for seven years.

Dr Magnus Pyke, Secretary of the Association and Chairman of Council, (pictured above) sees the BA as a "peripatetic university; it obtains its strength from movement". Certainly, to judge from those in attendance, it seems to recruit many of its officers and much of its following from towns which have been host to the association in the recent past. The ambience does seem to be very important and was a major factor in the success of this year's venue, as a result of "the intellectual richness of Scotland".

There was no feeling of nostalgia for the BA meetings of the past, at which many new results were communicated. Sir John made it clear that though original work would be very welcome, "the process of communicating science has changed completely since the early days of the BA". Dr Pyke feels that the function of the BA is to communicate a policy of social responsibility. Dear to Dr Pyke's heart are the working parties and their reports. But (as the reports reflect) Dr Pyke is adamant that the association should not adopt a radical role. "We don't want to tear down ICI" he told *Nature* vehemently. "We are hear to make the facts clear; period." He stressed that it is the aim of the BA to educate members of the public so that they will be placed in a position from which they can exercise their rights as informed voters.

But it is interesting to consider whether those present really constituted a random section of the non-scientific public that Dr Pyke is trying to reach. The meeting, and the publication of the report on Biomedical Advances that had preceded it, received a fair amount of press coverage and Sir John felt that there had been an encouraging amount of responsible reporting. Without doubt the BA has been actively promoting itself in the recent past and at last seems to have realised that it is the only way that it can reach the wide public audience with whom it claims to communicate.

There was certainly an age gap in those attending the meeting. Most were either under 25 or over 50 and the small middle-aged group of active scientists seemed to be there to organise or to speak. Schoolchildren seemed much in evidence, both organised and disorganised, and some of the more fortunate undergraduates and schoolchildren had managed to get grants from their local education authorities. In addition of course there were teachers, government and industrial scientists (with a sprinkling of academics) and the mild elderly ladies who go each year simply for enjoyment.

In fact, schoolchildren seem to be the part of the population which the BA reaches most effectively. Young members are joining local BAYS groups at a rate which is beginning to cause administrative headaches, and Dr Pyke wryly admitted that the situation was becoming embarrassing. Many members of Council, notably Sir Lincoln Ralphs, are enthusiastic about the interest shown by the young, but Dr Pyke himself has been criticised by both the youngsters themselves and by many BA officials, for his lack of interest in the juvenile membership. There was certainly little provision for them at this year's conference.

Whilst it must be admitted that Dr Pyke, in his role as Chairman of Council, has provided an immensely important element of continuity in the organisation of the BA, it is sad that his enthusiasm does not seem to extend beyond his individual view of the current welfare of the association. There will come a time when, like it or not, Dr Pyke and his generation will have to leave and it would be as well to prepare for that contingency. It would be a pity if, after the successes of the current resurgence, the BA has to spend yet another period in the doldrums for lack of encouraging their future membership now.

Job crisis or manpower crisis?

by Eleanor Lawrence

If you want to be a research biologist, a degree can be a hindrance, according to Professor Kenneth Mellanby, former Director of Monks Wood Experimental Station. Addressing the British Association, he said that promising school leavers now stand a better chance than the average graduate of a career in biological research.

The career structure of research institutes, especially those financed by government, favoured two types of scientific worker. There would always be room for the first-class graduate with a higher degree, although the number of such vacancies, already small, may decline even further as the Fulton proposals improving promotion prospects for junior staff come into force. At the other end of the scale, said Professor Mellanby, most Directors prefer bright school-leavers for junior research and technical posts, and there is no lack of these wishing to take up a biological career.

Although Professor Mellanby acknowledges the situation he is far from happy about it. If good graduates and postgraduates cannot get jobs in research the quality of research will inevitably suffer, he said. In his view, the scientist who had risen through the ranks, admirable though he or she might be at the job, would not have a similar capability for research.

Professor Mellanby's impression was of a "great over-production of graduates and doctors and high unemployment". But, in fact, after an initial disappointment, the biology graduate usually found a congenial niche in a variety of other occupations.

But industries requiring graduates with a specialised applied training such as chemical engineering or metallurgy are experiencing a shortage of trained graduates to fill an ever increasing number of jobs. In 1974 the number of applications for degree places in chemical engineering dropped dramatically at a time when the demand for chemical engineers had suddenly taken a rapid upwards turn. The number of jobs in chemical engineering advertised in the Institution of Chemical Engineering's 'Diary' had dropped from 742 in 1969 to 178 in 1972 but had risen to 405 in 1973 and in 1974 was expected to top the 800 mark, said Dr David Sharp of the Institution.

Was this decline in graduate applications simply a result of straightened job prospects during the early 1970s? Dr Sharp is convinced that the cause lies much deeper; physical science teaching at secondary school level is neither inspiring enough nor of sufficiently high quality to encourage the school child in this sort of career he said. No graduates with engineering backgrounds went back into teaching at secondary school level, so that schools careers officers were completely ignorant of courses and career prospects. The tiny proportion of physics graduates entering teaching also worried Dr L. Cohen of the Institute of Physics. Chemistry may fare better, as in 1973 about 15% of first degree chemistry graduates entered teacher training.

Industry would no doubt find ways of getting round the specific manpower shortage, said Dr Sharp. The slack would probably be taken up by people trained in related disciplines such as chemistry. But a shortage of metallurgists could hold up programmes of metal reclamation and recycling said Dr D. C. Moore, President of the Institute of Metallurgists, as university departments of metallurgy declined and in some cases disappeared.

So the "job crisis" tends to look rather different depending on where one is standing. A picture emerges, not so much of a crisis, but of increasing diversification amongst science graduates. Everyone was agreed that, except in the special cases of the applied fields, there certainly has been a drop in jobs which use scientific training directly. Some parts of industry had increased their recruiting this year, but in the present financial situation, the universities and the scientific civil service would take fewer and fewer people.

But the patterns of first year employment seem to be evolving to meet the changes quite successfully, though how much individual disappointment is hidden behind the statistics is hard to tell.

Diversification is not necessarily a forced choice. Salaries of professional scientists compare very unfavourably with their contemporaries in management or administration in both industry and the civil service. Dr R. E. Parker of the Royal Institute of Chemistry produced comparisons of salaries between research, technical and management grades in the chemical industry which clearly direct the financially ambitious away from pure science.

Employment or lack of it amongst science graduates must be set in the wider economic context. Dr Cohen emphasised that absolute unemployment amongst science graduates was still lower than amongst graduates as a class. And it was pointed out more than once that other graduates had always been in the position of having to find work unrelated to their specific training.

Only connect

by Gillian Boucher

Science undergraduates lack the critical training needed to see their subject in the broader context of society or even of science as a whole. This is the thread running through the many experimental curricula and proposals for change described during a week-long session at the BA. Motives and methods varied widely but the courses described fitted into two broad categories: traditional science taught alongside 'science studies' (the salad principle); and the interdisciplinary science course (the porrage or porridge principle).

Dr David Edge, Director of the Science Studies Unit in the University of Edinburgh, described the alternatives to the traditional British subject-oriented course. First, a course aiming to fit the student for a career. This might entail teaching an additional subject like economics, or a skill like decision making. Second, the course could be more geared to the personal needs of the student who may feel that his development requires more than a single science taught in a particular way. Third, courses could aim to make students of more immediate use to society as a whole.

There was complete agreement that the traditional science courses and subjects should remain on the curriculum. But there was strong support for the provision of alternative courses. The commonest reasons given were the interests of the student's future career and of society, the two often being treated as identical. In the eyes of Professor F. R. Bradbury of the University of Stirling the 'Advancement of Science' was no longer so much in the public interest as it had been when the British Association was founded: instead, students should learn to manipulate the scientific knowledge already attained and apply it to the messy problems of real life.

Those who preach interdisciplinarity are adamant that the porridge should be smooth. It is not enough to teach several subjects side by side as in a joint honours degree or the old general degrees. It is not even enough to allow the student a great deal of choice between course units. Integration requires a totally new approach—an emphasis on the connections between subjects, which will lead to the subjects themselves being taught differently. To create such a course is very difficult—Dr Edge stressed the danger of a superficial juxtaposition of subjects. This can only frustrate the thoughtful student who wants to read further and discovers no core of knowledge and research below the superficial link.

Most of the interdisciplinary courses in existence in the United Kingdom—for example those at Aston and Stirling Universities and the Middlesex Polytechnic—teach two or more traditional subjects and attempt to link them by means of problem-solving courses. In these students are presented with a real life situation and asked to consider all the relevant knowledge from the various disciplines in coming to conclusions. Thus the student develops a skill which is not demanded by a traditional course, and is presumably more personally fulfilled and more ready to pursue a career and be of use to society. Sometimes even more is asked of these subject-spanning courses—they are supposed to provide the basic framework for the study of the traditional sciences. Thus chemistry and cell biology are taught in the context of a marine pollution course at Stirling. Clearly the links in many cases are fragile but perhaps for some students the applicability to social problems is enough.

There are other dangers of which, says Dr Edge, the proponents of the new courses may not be fully aware. In a subject-oriented course with rigid boundaries between subjects, the teacher is in firm control of what the student learns and can withhold from him the realisation of the gaps and ambiguities in knowledge until near the end of the course. All this makes for a very clear relationship between teacher and taught, with the teacher in charge. Changing to an interdisciplinary course will remove subject loyalties and may disorient both teacher and student. The teaching of a subject as part of an interdisciplinary course will entail teaching its fundamental concepts at a much earlier stage, and omitting much of the detailed knowledge of the subject. This will tend to diminish the traditional status of the teacher which again will be disorienting to all concerned and will be fiercely opposed.

Some of these problems have already been encountered by those teaching the new courses. Dr Edge's views on the relative power of student and teacher would not be accepted by all—seemingly Professor Jevons of the Department of Liberal Studies in Manchester feels that the student doing a course on marine pollution was in fact far more at the mercy of his chemistry teacher than a student doing a traditional chemistry course. The problem of subject loyalties may be solved by providing teachers and students of interdisciplinary courses with an institution which has some of the trappings of

---

Scotland's future in the rocks

by Allan Piper

SCOTLAND'S economic salvation need not be entirely dependent on oil.

The quarrying industry in Scotland could soon be in a position to gain a substantial share in a market worth £2,000 million a year, which could have a considerable impact on the British economy, it was claimed in a lecture to the British Association. "It is fashionable to look on oil as the saviour of our economy", said Dr Colin Gribble, a geologist from Glasgow University and Mr Ian Wilson, an executive with Amalgamated Quarries (Scotland) Limited; but they claimed that, with the adoption of a scheme entailing the low-cost transportation of bulk material, high quality granitic material could become as important as oil in the longer term, both on the home and export markets.

Quoting government statistics, they said that by the end of this decade the annual demand for roadstone and construction material in Great Britain will have risen by 50%, so that an extra 100 million tonnes of aggregate will be required each year. The increased demand is likely to be particularly high in south-eastern England, a densely populated area already using a high proportion of the British annual production. Materials there are either very scarce or completely exhausted, and most aggregate is supplied from Cornwall, Leicestershire, and Wales. But the largest of these quarries, said Dr Gribble, can only produce about 2 million tonnes a year, and they do not have the reserves to allow for the increased output which will be necessary to meet the predicted growth in demand.

"We believe that Scottish quarries are in a position to supply a significant share of this demand. We also believe that we have the technology to supply that demand at competitive prices", said Dr Gribble and Mr Wilson. Their calculations depend upon the assumption, reasonably based on an extrapolation of present trends, that the cost of aggregate in 1980 will be about £10 for a delivered tonne at today's prices.

All that is required, they argue, is a novel modification of the present system of quarrying. They suggest that massive quarries, with reserves of over 100 million tonnes, should be developed in remote, granitic areas close to the coast. Each quarry would be worked to produce about 10 million tonnes a year. Such massive reserves, coupled with the intensive output, would reduce the cost of land fees, manpower, and plant renewal, and the consequent reduction of necessary capital investment would render the industry extremely cost-effective, it was claimed. And the location of the quarries near to the sea, preferably close by deep-water harbours, would provide easy access to a convenient and relatively economical means of bulk transportation. Labour requirements should provide little problem, according to Dr Gribble, as only about 100 men would be required to work a quarry of the envisaged size.

"Sites for these very large remote quarries would be carefully chosen and landscaped, screened from view, and so on," said Dr Gribble. He suggested that the development of 10 to 20 such quarries, located almost entirely on poor agricultural land, might be more desirable environmentally than the continual opening of smaller quarries in populated areas as the demand arises.

Mr Wilson's company already has two quarries on the east coast, at Peterhead and Inverkiething, which, it was claimed, could easily be developed on the proposed scale once the market became ready. And Mr Wilson knows of at least two other quarries in Scotland, which are in a similarly advantageous position.

The quarries at Peterhead and Inverkiething are, according to Mr Wilson, already capable of supplying material by sea not only to south-eastern England, but also to northern Europe where there is a similarly increasing shortage. He is quite confident that, if the suggested ideas are implemented, Scottish quarries could eventually provide as much material for export as for the home market; "we already have customers in Germany and France anxious to buy this material from us", he said. Both he and Dr Gribble are optimistic about the future of the Scottish quarrying industry which they believe could considerably bolster the future economy of Britain.

a department. A further problem is a shortage of reading matter. SISCON—the one-year-old Science in a Social Context project—is trying to fill this gap. A group of eight universities and one polytechnic running science studies or interdisciplinary courses have been given £50,000 by the Nuffield Foundation to produce course books which are flexible enough for a wide variety of courses. Dr W. F. Williams, the SISCON project coordinator, sees the job as essentially short term. The aim is to produce as wide a range of teaching material as possible and if within ten years this is not being supplemented and replaced by books written outside SISCON the whole idea will probably have been a failure. Dr Williams is also toying with the possibility of sending a researcher to Nigeria to gauge the need for similar publications in Africa.

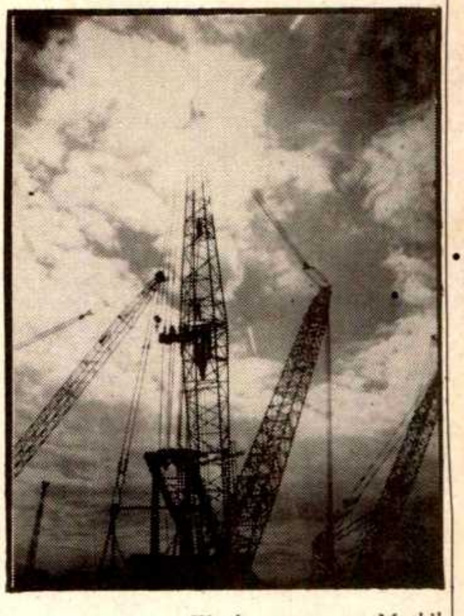
And what of the courses that do not attempt to break down the traditional boundaries? Dr Edge's institute in Edinburgh provides only one quarter to one half of a student's work for one year. Dr Edge aims to give students an awareness of science—its internal behaviour and its relations with the world—without taking up so much of his students' time to prevent them from progressing to scientific research if they wish.

Professor Jevons's department in Manchester similarly offers a single unadulterated science alongside science studies. But the entire course—science and science studies—is within a single department and Professor Jevons does not aim to produce scientists ready to do research. The students only spend half their time doing science and the other half looking at science in its social, historical and economic context.

Undergraduates prefer to be taught distinct subjects rather than a homogenised baby food, said Professor Jevons. It would be a pity to break down the real outlines of the traditional subjects in order to erect the flimsy bridges between the interdisciplinary courses. Yet students want to participate and debate and learn to take decisions. Since the well-worn precepts of the physical sciences are patently unsuitable material for this style of teaching, the best solution is to teach students something else besides their science. In Professor Jevons's department this something else is science studies, which can be taught by science teachers. This part of the curriculum develops the student's critical faculties which are by necessity blunted in the acceptance of scientific truths. The student becomes more aware of the role of science in the world and perhaps even a better scientist.

A final word of warning against the excesses of interdisciplinarity. Professor Kendrew reminded the meeting that certain "hard" subjects such as mathematics had to be learnt young or not at all. The early molecular biologists showed that it was a positive advantage to enter a field of which you had no previous knowledge, as long as the basic mathematical ability was there. And certain subjects could very properly be picked up by the student or graduate when he felt a need for them—witness Professor Kendrew's success with crystallography. ☐

As a rest from the round of lectures and seminars, British Association members had the opportunity to look around Redpath Dorman Long (North Sea) on the Fife coast. The little village of Methil on the coal coast of Fife once boasted a thriving colliery but since the 1960s unemployment had increased and the area had begun to show the inevitable signs of industrial dereliction.



Work returns to Methil

But in 1972, RDL (North Sea) set up at Methil, on the disused 136-acre colliery site, when the company was formed from a consortium of British and Italian interests. RDL, a subsidiary of British Steel, hold a 55% increase and the remaining 45% is held by three Italian companies with long experience in the design and construction of oil production platforms in the Mediterranean and the Middle East.

RDL's first steel jacket, for the Auk field, was successfully placed in position on its 280 feet deep water site this summer, and RDL are now building an even bigger structure for the 480-foot deep Brent field. As the weight of the structure varies with the square of the depth of the water, this platform is twice as high and four times as heavy as the 4,000 ton Auk platform. RDL have also started work on a comparatively tiny gas production platform for the Danish Dan field.

The site at Methil could certainly cope with at least one medium and one large-sized jacket at the same time, said a company spokesman. In this RDL think they have an advantage over some of the other steel platform constructors, who use the flotation tank method for building and floating out platforms and thus can build only one at a time. RDL build their platforms on dry land and then manoeuvre them onto submersible barges which carry them out to the site.

The Methil site has only 30 feet of water for floating out but this is perfectly adequate for the steel jackets which are towed out on their sides. RDL also have on offer a steel/concrete hybrid gravity platform but as yet have no takers. This design can also be built at the Methil yard and is suitable for water depths up to 600 feet, rivalling the concrete platforms.

Social concern

Mrs Shirley Williams, Secretary of State for Consumer Affairs, drew the attention of a British Association symposium to the difficulties that politicians find in keeping in touch with science. "When I was a minister with responsibility for science", she said, "I found that ministers with such responsibilities are not in touch with scientists" Speaking during a symposium on the British Association report on Social Concern and the Biological Sciences, Mrs Williams, a member of the working party who conceived the report, said that she had been dependent on a few and sometimes only one scientific adviser. There must be more round-table discussions such as the British Association can provide on controversial biological and medical advances, she said. Parliament badly need greater education and more information. Many of these topics are very suitable one for a free non-party vote but only amongst informed men and women, Mrs Williams concluded.

The working party has been criticised in several quarters for producing a non-report. Countering such criticisms, Professor Bodmer promised that they would now draft concrete proposals and press for these to be put into effect. The working party's life is to be prolonged by a fresh infusion of funds from the Leverhulme Trust, and in its future incarnations will widen its scope to cover other biological advances such as the genetic manipulation of bacteria, but would not venture into thorny paths such as pollution, population and behavioural control. ☐

Science and politics of molecular biology

by Eleanor Lawrence

MORE money for molecular biology could be the most cost-effective way of reducing Britain's massive health bill, according to Professor John Paul of the Beatson Institute for Cancer Research. Professor Paul told the British Association Annual Meeting that Britain is now approaching the limits of what our society can pay for in terms of direct medical care, and the only way to eventually reduce the bill was by a three to four-fold increase in government funding for biomedical research and especially for molecular biology.

Ill health costs Britain about one quarter of the annual Gross National Product each year when loss of production and social security benefits are included. But medical research accounted for £800 million, only 0.15% of the total GNP (1972 figures), of which the government contributed £25 million to basic research through the Medical Research Council. Defence research on the other hand was supported to the tune of £250 million in the same year.

In the past, biomedical research had brought the infectious diseases more or less under control, said Professor Paul, and indeed we could not afford such massive spending on ill health now, if this had not happened. But we are now left with a residue of degenerative diseases and the second most frequent cause of death—cancer, which had proved difficult to combat by traditional medical means. Professor Paul believes that we are on the brink of a rapid advance in the understanding and treatment of cancer, and that this will result from the application of the ideas and methods of molecular biology.

Twenty-one years of basic research in molecular biology have brought it to a point at which, through the relatively new branch of 'molecular pathology', its principles and methodology can be applied to the study of disease. About £1 million is spent on molecular biology, of which the MRC contributes the greatest part. Although research into molecular biology takes up about 5% of the MRC budget, in national terms this is very modest financing compared with for instance the United States. Professor Paul believes that molecular biologists should not hesitate to become involved in the 'political' arena and argue on political and social grounds for an increase in government finance as it is becoming increasingly clear that molecular biology ("that apparently most abstract of biological sciences") is a highly political subject. □

Room at the top in space

A YEAR ago the ministers of the 10 European Space Research Organisation (ESRO) countries reached final agreement on the formation of a single European space body—the European Space Agency, and a package of projects on which to embark itself. The Agency was due to come into force on April 1 1974, already three months later than the original target date, but in the event this date too proved ill-chosen. The ESA is still not in being.

The lapse is more apparent than real. The money is secure with guarantees from each of the 10 member countries and with what amounts to a bond deposited on the largest project of all—the $300 million development of the Spacelab element in the American space shuttle programme for the 1980s.

Most of the planned projects are trundling on and fairly well on schedule and within their budgets. A key meeting of national delegates takes place on September 27, and at the full ESRO Council on October 8 there is every hope that 'baptism' of the new management can be confirmed.

It may take another two years for the ESA Convention to be ratified by all 10 member states. In the meantime the organisation continues to run on the ESRO Convention. ESRO is already a very different animal from the ESRO of last year. The total budget this year is $240 million, against a mere $40 million in 1973. The Spacelab contract has been let. The more than two years of stalemate on the joint US-ESRO-Canada Aerosat project—to set up a pre-operational system for evaluation of air traffic control and navigation satellites in cooperation with air-lines flying the Atlantic—has been resolved. This has hinged on what to Europeans has seemed a technicality, finding an acceptable industrial partner among American companies to act for the US Government opposite ESRO and Canada on the management board. The Memorandum of Understanding between the three parties originally to be signed in January 1972 was finally completed in Paris last month. Last week the Aerosat Board chose Comsat (out of five contenders) as the American partner and its head visits Paris soon to persue details. The target date for launching the first Aerosat over the Atlantic, mid-1978, should now be met.

The credit for most of this must go to the head of Administration, Roy Gibson (pictured above), who has been acting director-general for the past months and was ESRO's chief negotiator at the original Aerosat talks in 1971. Latterly the work of the eight senior posts in ESRO has been shared between three people, with Gibson sustaining the lion's share.

In the face of the increased volume of work this hiatus at the top at ESRO has been serious. Two of the best men among ESRO's senior and most experienced staff have left for good. The five senior posts that are vacant cannot be filled till the director-general is appointed, since political considerations enter into the distribution of seats among the member countries. Of the sitting executives, one is English, one a Swede, one Italian. The most widely promoted candidates for the top job are the French ex-head of ELDO, the much respected General Aubinière, and a German civil servant, Dr Schmidt-Kuster. There is also a case to be made for Gibson himself. □

Plugging the hole in Skynet

from Angela Croome

"TRYING to pour a water-butt through a bootlace" was how one Services officer described pre-satellite long-distance communications for defence. That was in 1969 when Britain first adopted a satellite-borne defence communications system—*Skynet*—for its own exclusive and interference-free use, making Hong Kong and ships at sea (in the Gulf of Carpentaria for example) as instantly accessible as Aldershot from Whitehall. Although the satellite itself, Skynet I, was built (to a tight £6 million contract) by Philco-Ford in America, the hard-headed specification was British and the ground-based terminals to communicate with it were British-designed and built. The Skynet system must rank as the most enterprising and successful British space venture yet achieved with several world 'firsts' to its credit. It was the first operational defence system to use a geostationary satellite; and, the 3½-foot shipboard terminal, Scot, remains the smallest and most ingenious 'earth-station' for satellite communications yet developed, and the envy of the US Navy.

The original Skynet satellite (Skynet I) has now exceeded its planned operational life and is due for replacement. To ensure continuous operation in all circumstances the original satellite, poised over the Indian Ocean, was duplicated. The second could act as standby if the first developed faults; otherwise it could provide additional capacity in an emergency. In the event only one of the Skynet I series ever became operational. In its companion the solid fuel packing of the centrally situated apogee motor had an undetected crack which caused the motor to explode on ignition, effectively disposing of the satellite at the same time. It seems that the single Skynet I in orbit managed to sustain its role without a standby.

Skynet: the ship-borne end

Last January the first of two replacements was launched by Thor-Delta from Cape Canaveral. It too came to grief so now there is the prospect of the second, Skynet II, phase of the system, also operating with a single satellite despite 100% planned redundancy. On this occasion the second stage of the launch rocket misfunctioned in the sense that the jets of the motor jammed hard over while firing, causing the vehicle to corkscrew wildly and subjecting the satellite to forces greatly exceeding those allowed for in the design specification. The satellite was 'missing presumed lost' for three days but was then picked up by a United States Air Force tracking station over the Pacific. It was still functional and responding to interrogation and commands but in a hopelessly low orbit. An attempt to 'kick' the satellite out to an orbit clear of the Earth's atmosphere with the onboard apogee motor failed. Nonetheless the British contractors, Marconi Space and Defence Systems Ltd, were well pleased with how well the spacecraft had stood up to its very rough passage.

In the last week of August the standby Skynet II was dispatched to the United States in readiness for launch in November to take over Britain's overseas defence communications role for a further three years. The overall design and engineering concept of Skynet II is similar to Skynet I; it may be considered a 'stretched' Skynet I. It is about a third larger than its predecessor, however, and has a considerably greater communications capacity. The ease, convenience and immediacy of 'voice-contact-by-satellite' has, not surprisingly, proved popular with the Ministry of Defence, as transatlantic businessmen similarly welcomed the coming of Intelsat.

Demand for faster telecommunications grows with supply. This has become a truism in the world of commercial telecommunications. Predictions of the growth of phone traffic and especially overseas phone traffic are always too low. No doubt the same can be said of defence communications. It is not difficult to imagine the asset that Skynet must have been and still is to the British bases in Cyprus during the recent emergency. Yet the future of Skynet is hazy. No decision has yet been made on a backup for Skynet II, although the end of its planned life is not so far off. Defence planning—where a new weapons system for instance takes ten to twenty years to develop—has long made nonsense of five-yearly changes in Government. Can anything so fundamental to the total defence operation as communications, be left to the shifts of party politics? While Britain continues to have overseas defence commitments, a return to "bootlace" communications would be a false economy.

Life sentence

AN astronomical surprise for dilettantes and professionals alike was provided by Sir Bernard Lovell during a discussion at the BA meeting. He delivered a severe body blow to the popular notion that there may be around 100,000 technological civilisations in our Galaxy.

In the past, Sir Bernard said, one extremely important factor had been omitted from the calculations. Nobody had yet taken account of the fact that at least 90% of the 100,000 million stars in the Galaxy are K or M stars, which exhibit characteristics that could well preclude the development of organic life in their vicinity. For a start, they only exist for about 10 to 100 million years before becoming black dwarf stars.

It is extremely unlikely that these stars could develop a solar system in so short a time, and in any case that hardly seems long enough to allow for the evolution of an advanced civilisation. Which is just as well really, because any organic life which might evolve would find itself in an extremely inhospitable environment.

Sir Bernard explained that K and M stars have extraordinary flare properties: blasts often last for periods of up to several hours, during which the normal intensity of emission doubles. The radiation effects would of course be quite lethal to most complicated life forms. □

● BECAUSE of an error in transmission, *Nature's* account of the recent NAS statement on plasmid engineering contained an inaccuracy which might have caused a misunderstanding about the moratorium. Under the heading of types of research which should be halted, we listed "autonomously replicating bacterial plasmids that might result in the introduction of genetic determinants for antibiotic resistance or bacterial toxin formation into bacterial strains that do not presently carry such determinants . . ." This should have read: "Construction of new autonomously replicating bacterial plasmids . . ." etc. We regret any inconvenience this error might have caused. □

Canada gets a new science minister

from David Spurgeon, Ottawa

'Bud' Drury: experienced Trudeau man

CANADIAN scientists are pondering the implications of federal government appointments that have followed in the wake of July's general election. A Cabinet shuffle has brought a new minister and secretary (deputy minister) to the Ministry of State for Science and Technology, which celebrates its third birthday this autumn.

Actually, "new" is not quite the word for the man named to head the ministry as successor to the Hon. Jeanne Sauvé, now minister of Environment Canada. C. M. ('Bud') Drury is not only one of the most experienced members of the Trudeau Cabinet, having served for some years as president of the Treasury Board—he was also *de facto* minister of science before such a post existed officially. This responsibility fell to him for a number of reasons: his post with the Treasury Board, his position as the minister to whom the National Research Council of Canada reported, and his chairmanship of the Privy Council committee on scientific and industrial research.

In addition to the science and technology portfolio, Mr Drury has been given Public Works, and the question scientists are asking is, does his dual appointment indicate a downgrading of science in the priorities of the government, or does this appointment of a senior and experienced Cabinet minister indicate an upgrading of the ministry?

In terms of experience, Mrs Sauvé was a junior minister, science and technology being her first ministry appointment. Her move to Environment Canada can only be seen as a promotion, because it is a far larger department.

Her predecessor, Alastair Gillespie, who was Canada's first science minister, was also a new boy, who has since been promoted to the Ministry of Trade and Commerce. The fate of these first two science ministers confirms the idea that the government has been using the post as a training ground for rookies.

But now the issue is complicated by the rumour that Mr Drury's appointment as science minister is a temporary one. This poses two questions: Who will be the permanent minister? And will the new appointee have more or less political clout than Mr Drury?

Some see Mr Drury's appointment as a holding operation—yet a choice that will assure no reduction of importance accorded science in federal policy, because of his personal experience in the field. Because the ministry is not an operational department, its political influence depends largely on the status of the minister, or the importance attached to the portfolio by the Prime Minister, or both.

The implications of the new deputy minister's appointment are not entirely clear, either. Formerly deputy minister of health, Dr Maurice LeClair is expected by some to exert a more cohesive force on the day-to-day operations of the science ministry than his predecessor, Dr Aurèle Beaulnes.

But some expect his policies to be a good deal less open: Beaulnes was always ready to talk to the press (usually at great length); health ministry officials have been more secretive and restrictive. In fact, Dr LeClair went so far last spring as to issue a directive prohibiting health department scientists from attending a forum on science policy set up by SCITEC, an umbrella organisation that is striving to represent all branches of science and technology in Canada. The given reason was "that this whole area of science policy is at such a ferment at the present and so deeply tied in with basic government policy that it would be inappropriate for our scientists to be in attendance at the SCITEC meeting."

Later, on the day of the conference, after a public service union pointed out to the department that the directive abrogated personal freedom, and that a scientist was already bound by an oath of confidence to the government, the department modified its stand: its scientists could attend as long as they did so as individuals and not as representatives of the department.

Both Drs LeClair and Beaulnes have medical backgrounds, which is a cause for concern among some scientists who feel this key post should be assigned to someone whose training and experience better equips him to understand research in all fields.

First Netherlands satellite in orbit

THE first Netherlands scientific satellite ANS was launched from the Western Test Range in California by NASA on August 30, 1974, by a four stage solid fuel Scout rocket serving as launch vehicle.

The Astronomical Netherlands Satellite carries three scientific experiments for astrophysical observations and comprises instruments for the measurements and classification of stellar UV radiation and X-ray sources in space.

The spacecraft's systems are in good condition and the attitude acquisition phase during which one side of the satellite will be locked to the sun, is running as planned. However the rotation around the Earth differs from the original planned near-circular orbit of about 500 km altitude as present orbit has an apogee of 1150 km and a perigee of 260 km.

In the coming days all systems of the satellite will be checked and calibrated before measurements are initiated. In spite of the deviation in altitude it is expected that by reallocating and adapting the observation programme the planned investigations can be executed according to schedule and will last for at least half-a-year before leaving the sun-lit area. For the first time complete operation control of an European satellite is performed at ESOC, Darmstadt, in Germany, by a team consisting of Dutch NLR and ICANS members.

Indians' blast

A PUBLIC opinion poll of 250 adult literates in each of the cities Bombay, Calcutta, Delhi and Madras shows how strongly the Indian public feel about the recent nuclear blast. The questionnaire conducted by the Indian Institute of Public Opinion reveals that 89% of the sample believe that the test has raised India's prestige in the international community and 80% believe that peaceful nuclear explosions will help faster economic growth through use in mining and other fields. Nearly a half want to supplement the peaceful uses programme with a programme to build nuclear weapons while only a third of those questioned wanted the government to use nuclear energy solely for peaceful purposes.

Successor to Anger's gamma camera?

DURING the past fifteen years gamma cameras have been introduced into the regular hospital armoury of nuclear medicine In the hands of a specialist this camera became a diagnostic tool of great importance, particularly for detecting and localisating cancer lesions The generation of γ cameras in current use derives its pedigree from the concept of Hal Anger (*Rev scient Instrum*, **29**, 27, 1956), who used lead collimators to produce an image of the radioisotope distribution in a scintillating crystal viewed by an array of photomultipliers On page 132 of this issue of *Nature,* Todd, Nightingale and Everett propose a new principle of γ-ray imaging Using arrays of position-sensitive detectors and selecting multiple interactions it becomes possible to calculate the position of the source of a γ ray from the formula for Compton scattering In this way the use of collimators is completely avoided The image formation in the proposed system is different from that in the Anger type of camera Instead of building up the image from a dot pattern, the Compton γ camera produces families of ellipses with the common point corresponding to the source of radiation

The method of implementation of the new concept is hardly mentioned in the communication In fact, the success of the proposed system probably depends in a most crucial way on the nature of the radiation detectors and on efficient, very fast collection of data Recent developments in the technology of solid state detectors and the availability of very fast mini-computers are making the proposals a practical possibility, but it is worth noting that to date no commercial γ cameras based on semiconductor detector technology are offered The Southampton group is therefore attempting to improve the design of the gamma camera in more ways than one

The main advantages of the proposed new system lie, first, in its ability to collect γ radiation over a larger solid angle than is possible through a system of collimating holes, with a corresponding reduction of the necessary patient dose, and, second, in the possibility of attaining higher positional resolution than the existing cameras Modern high performance Anger cameras have resolution indices of about half a centimetre The authors' estimation of the resolution possible in their system is in the region of 1–2 mm The ability of detecting smaller malignant lesions is always uppermost in the minds of clinical diagnosticians

With a suitable fast data collecting system the high potential sensitivity of the Compton γ camera will make it the instrument of choice for fast dynamic studies with radioisotopes, for example, for the study of cardiac output and the blood circulation in limbs Furthermore, as Todd *et al* indicate, the computing system associated with the camera can select events originating at a certain depth in the body and can thus yield the tumographic information in any desired place

It remains to be seen if the Southampton group, after presenting a new and exciting idea, will be able to break through the technological barrier and produce a working model of the camera that will make it possible to evaluate all the predictions and expectations of its performance

What makes a molecule odorous?

THE olfactory quality of a molecule has always proved notoriously hard to predict, but another attempt has recently appeared (Schiffman, *Science,* **185**, 112, 1974) This work is mathematical in nature and applies multidimensional scaling to known data

How much progress has been made since the confrontation between Amoore and Wright in the pages of *Nature* a few years ago (**233**, 231, 270, 1971 and **239**, 226, 1972)? In particular, can one yet distinguish between the theories of Amoore, Wright and Davies, preferably by a clear refutation of two of these theories?

The answers to these questions are complicated by the modifications that all three theories have undergone in recent years, and it seems also that the number of olfactory theories is growing, rather than diminishing (A full account of the principal theories and results up to 1970 may be found in *Handbook of Sensory Physiology,* **4**, (Part 1, Olfaction), Springer-Verlag, 1971)

Schiffman uses measures of psychological similarity as the input for her multidimensional scaling if two substances are judged by human subjects to have quite similar odour qualities, these two substances are placed near each other in multidimensional quality space Of course this is not new in itself, but what is new is that the known similarity data are now re-analysed by a general non-metric multidimensional technique, which shows that only two dimensions are required to account for the known similarity relationships between many different compounds

What new information emerges from such two-dimensional odour maps? First, it seems that there are no sharply defined areas which would correspond to possible 'primary odours'—the odour types all merge into one another, for example, from floral and fruity areas to areas of resinous (for example, turpentine-like) odours Or, in Schiffman's words "There are no clear psychological groups or classes of stimuli, merely trends" Unfortunately, she does not present any data on 'musky' compounds, usually regarded as constituting a well-defined group

Second, can these psychological similarities be related to the usual molecular properties? Schiffman claims that Amoore's original (1952) theory that molecular shape

This is the last News and Views prepared by Sally Bunney who after nearly seven years with *Nature* is off to a post as medical librarian in Oman She goes with the best wishes and affection not only of the staff but also of an army of correspondents Mrs Gillian Boucher takes over Miss Bunney's position uniquely determines olfactory quality is not confirmed, but this conclusion was reached some years ago by Amoore himself, who modified his "site" theory to account for trends rather than for sharp "fit" or "not-fit" categories of molecular shapes.

As regards Wright's spectral theory, this gives a good correlation with the odorants in two broad categories (pleasant and unpleasant), but five pleasant odorants are incorrectly classified as unpleasant on the basis of their Raman spectra.

As regards the "penetration and puncturing" theory of Davies, in which the lipid part of the plasma membrane is held to be responsible for olfactory effects, Schiffman reports that lipid solubility may be necessary for olfactory stimulation to occur (since all the odorants were soluble in ether and there was no trend of odour type as a function of water solubility). There is apparently no evidence against the two-dimensional odour map earlier published by Davies.

So no single physico-chemical variable can account for odour qualities. But how many such variables are required? Schiffman used suitability weighted functions of Raman intensity, molecular weight, number of double bonds, functional group and cyclic structure, these being taken as simultaneous but separate variables which, empirically weighted in combination, are used to correlate molecular properties with the psychological similarity map. Altogether 25 weighting factors are chosen to give the best fit. The final correlation coefficient is 0.76, which in these circumstances is distinctly disappointing. as Wright has pointed out, Amoore's odour similarity values (admittedly over a limited range of odour) have a correlation coefficient of 0.85 with the square root of the molecular weight. Furthermore, as Mazziotti has shown (*Nature*, **250**, 645, 1974), there is even quite a fair correlation between odour type and boiling points, particularly within groups of substances whose molecules have the same functional group. Perhaps Schiffman's most important contribution to the debate is that molecular shape as such is not said to be significant.

Future progress in the field of odour must surely be concerned with mechanism of the initiation of the nervous impulses in the olfactory epithelium. Adrian, many years ago, found that different regions of this epithelium in the rabbit and the hedgehog are relatively selective to stimulation by certain types of odorant molecules. Since the lipids may well be responsible for the initial adsorption of the odorants from the air stream, and since the lipid structure may then be locally disorganised by the odorant molecules, one predicts differing properties of the lipids in the various regions of the olfactory epithelium.

This urgently requires testing experimentally by an analysis of lipids taken from the various regions of the epithelium. Only by experimental tests of such physical theories is there likely to be real progress in the understanding of olfaction.

Clonal selection hypothesis under fire

BIOLOGICAL research in recent years has acquired various dogmas, the most famous of which is probably the central dogma of the molecular biologists. Immunologists, not to be outdone, have espoused the clonal selection hypothesis as their central concept to provide a framework for the understanding of classical antibody synthesis. A recent statement of this notion says "Antibody molecules consist of heavy and light polypeptide chains, the variable sequences of the 110 N-Terminal amino acid residues of these chains determine antibody specificities; lymphocytes are cells that express one pair of structural genes for these sequences; *one lymphocyte and all of its descendants make identical antibody molecules* (my italics); these are placed as receptors for antigen on the outer lymphocyte membrane; the attachment of antigen to the combining sites of these receptors is a step in lymphocyte stimulation leading to cell proliferation, antibody secretion, and thus to an amplification of this selected antibody" (second *Annual Report of the Basle Institute for Immunology*, page 1).

Although several of the items of this concept thus stated could be questioned, the present interest is in the italicised phrase which seems to be contradicted in part by a recent communication by Cunningham and Fordham (*Nature*, **250**, 669–671, 1974). These investigators present evidence that sometimes single antigen stimulated cells can engender clones of cells of which not all the members of the clone are producing the same kind of antibody.

Mouse spleen cells were cultured *in vitro* in the presence of bacterial lipopolysaccharide and sheep red blood cells. After 24 h the cells were harvested and dispersed in microdroplets under oil in fresh medium with a mixture of red cells from two standard sheep and complement. In these circumstances the antibody from some of the cells diffuse into the surrounding medium and, in the presence of complement, soon lyses the sheep red cells giving rise to a more or less clear plaque around the antibody-producing cell. The plaque-forming cells were isolated by micromanipulation from the microdroplets and seeded on to a feeder layer of irradiated mouse spleen cells and sheep red cells were again added. After about 2 days some of the isolated plaque-forming cells had divided. Their progeny cells were re-isolated where necessary in the presence of trypsin to disaggregate them and they were added individually to a mixture of fresh medium, complement and red cells from the two standard sheep. These mixtures were pipetted into Cunningham slide chambers (Cunningham and Szenberg, *Immunology*, **14**, 599, 1968), and the resulting (19S) plaques were characterised as either clear, partial or 'sombrero'. Clear plaques are supposed by the authors to arise around cells which have produced an antibody (or antibodies) which recognises antigens common to both the target red cells. Partial plaques have some unlysed red cells and (despite the lack of a morphological criterion of distinction) these are interpreted as arising around cells which produce antibody capable of binding effectively to only one of the kinds of red cell. Sombreros are supposed to arise around cells which are producing antibodies for common specificities but with higher avidity for one of the kinds of red cell than the other. About 10% of all isolated cells formed clones and of these about 10% were found to give rise to heterogeneous plaques. Most of the heterogeneous clones had only two kinds of plaque forming cell. Two had three kinds of cell and one clone (of twelve cells) gave rise to four clear plaques, five sombreros and two partials. One could not be diagnosed.

On the basis of these results the authors postulate that, contrary to the precepts of the clonal selection theory, diversity in relation to antibody-producing capacity can commonly (if not always) arise after contact with antigen rather than be pre-existent. The approach is ingenious and owes much to the use of the polyacrylamide gel microculture plates developed by Marbrook and Haskill (*Cell Immunol*, in the press). Whether the evidence presented by Cunningham and Fordham will withstand the barrage of criticism which will be put up by the immunological establishment remains to be seen but it is healthy that after such a long run unopposed, the Clonal Selection Theory is taking a few knocks.

A J S DAVIES

Can neutron starlight be seen?

AMONG the more exotic inhabitants of our Galaxy are the enigmatic neutron stars Although these objects are about the same mass as ordinary stars, they are only a few kilometres in diameter, and are therefore unbelievably dense So much so that their constituent atoms are entirely crushed by gravity into neutrons Despite having been predicted theoretically for many years, firm evidence for their existence had to await the discovery and interpretation in the late 1960s of the now famous pulsars Pulsars are radio sources which emit bursts of energy at very regular durations, usually about once a second Current models of these cosmic clocks assume their regular ticking to be caused by the rapid rotation of an extremely compact object coupled to a magnetic field The compact object is generally thought by astronomers to be the long awaited neutron star, born during the violent aftermath of a supernova explosion

Models of the pulsar mechanism are necessarily tentative, but the pulses of radiation are believed to originate not from the neutron star itself, but rather from the surrounding magnetosphere This then leaves open the question of what radiation might be expected direct from the neutron star surface The answer to this depends on the temperature of the surface, which is really an unknown factor General considerations, however, point to this radiation being in the X-ray region, so that the exciting possibility emerges that the nascent science of X-ray astronomy might provide important data for astronomers studying neutron star structure and pulsar mechanisms

Actually, the idea of searching for X-rays from neutron stars is not new Before the appearance of pulsar astronomy, it remained the best hope for the eventual discovery of these strange objects The excitement generated during the past few years by the spectacular pulsars has, however, quite eclipsed the consideration of X-ray detection of neutron stars, and the subject makes a new appearance in the August 9 issue of *Science* (**185**, 487–490, 1974) The resurrection is promoted by two American astronomers, Greenstein of Amherst College Massachusetts, and McClintock of MIT These authors point out that this X radiation bears the same relation to neutron stars as continuum starlight does to ordinary stars And where would astronomy be without starlight?

Recently, strenuous efforts have been made to construct theoretical models of neutron stars The problems involved are formidable, for in almost every respect these objects represent matter in an extreme condition Indeed, the entire neutron star may be envisaged as a sort of gigantic atomic nucleus A correct understanding of such a strange object requires advances in several separate branches of physics Consequently, a direct observation of neutron star radiation would provide the only source of observational support for theories of matter in this high density condition

Specifically, Greenstein and McClintock suggest five pieces of information which could be deduced from a careful measurement of X-ray spectrum The spectrum itself would give the surface temperature of the star and hence, knowing the total flux, its radius could then be estimated, thereby confirming (or not) that the source really is a highly compact neutron star In turn the radius could be used to determine the mass and the pulsar magnetic field, at least approximately In addition, a knowledge of the magnetic field, temperature and mass enables the age of the neutron star to be calculated, with the possibility of a fruitful comparison with the associated pulsar age which may be deduced from the rate of slowing down of the pulsar period Finally, it is in principle possible to determine the internal temperature of the star, with a possible cross check here too from the details of the quasi-exponential period decay which has been observed to occur after peculiar period jumps in the radiation pulses

In their article, Greenstein and McClintock outline three theoretical procedures which may be used to obtain an estimate of the temperatures of neutron stars The first is simply to try to calculate the rate of cooling as from the time of formation The second is to examine various dissipative processes which generate heat inside the object as it rotates In both these methods the condition of the relevant theoretical models does not inspire much confidence in the result, so that a crude upper limit may be placed on the temperature by summing the total available energy Turning to the observational aspects of the subject, the authors paint a rather pessimistic picture There is no observational evidence at all yet for thermal X rays from neutron stars The best potential candidates are thought to be the middle aged pulsars—perhaps 100,000 years old —whose direct radiation would not be swamped by the pulsar radiation from the magnetosphere From the present non-detection of X rays from the known pulsars by the Uhuru X-ray observatory, upper limits on the temperature of 21 nearby pulsars are quoted A comparison of a sample of these limits with the theoretical values obtained using the three methods described above is presented Unfortunately, in all cases the theoretical values lie well below the observed upper limits, so that little of value may be gleaned from this

Despite the rather discouraging situation so far, Greenstein and McClintock argue their case well, and it would be surprising if further observational and theoretical work were not initiated on this difficult but important topic for astronomers And in view of the fact that the neutron star represents the most extreme density of matter in the observable Universe (greater densities lead to unobservable black hole matter) there is also a general scientific interest in their direct observation

Checking on laser fusion

from a Correspondent

IN May this year, KMS Fusion Inc claimed to have produced, for the first time in the United States, thermonuclear neutrons from a laser-compressed deuterated target (The background to the laser-compression approach to fusion is outlined in *Nature*, **239**, 139 and 129, 1972) K M Siegel, chairman of the company, later amplified some of these claims, which are the outcome of a private corporate investment which now amounts to $17 5 million, in a talk given at Harwell on July 8

Between May 1 and July 8, about 35 neutron-producing shots on deuterated and D–T targets had been made, of which 80% were successful The prompt neutron yield (measured with a time resolution of 2 ns) was as high as 5×10^5 when the target chamber was evacuated, the total yield increased to $1\ 8\times10^7$ when deuterium gas was admitted to the target chamber (The latter result duplicated earlier Russian yields, in which neutron time-of-flight measurements were made with a detector resolution of 5 ns over flight paths of more than 3 m) X-ray pinhole photographs, with a spatial resolution of 5 μm, demonstrated that the implosion and compression of a hollow target was spherically symmetric Time-resolved X-ray emission measurements suggested that a density increase of 80 times occurred when two opposing Nd-laser beams (total energy $<$ 100 J) were focused by ellipsoidal mirrors on to the (suspended) solid state target

This compression, and the prompt neutron yield, were said to be consistent with computer predictions

These claims have unleashed some controversy within the international scientific community Everyone agrees that 'scientific break-even', in which the energy of the neutron output is roughly equal to that of the incident laser pulse, would produce so many neutrons (~ 10^{14}) that a detailed and unambiguous determination of their spectrum and physical origin would be possible Severe problems arise, however, with neutron diagnostics at the present level where, relatively speaking, only a handful of neutrons (10^{-8} of the break-even yield) are available for examination Additional diagnostic techniques which can provide independent checks on plasma density or temperature are therefore necessary until well documented 'break-even' yields have been achieved

At densities less than approximately 10^{19} electrons cm^{-3}, measurements of refraction or scattering have often proved a reliable diagnostic Attwood and Coleman (*Appl Phys Lett*, **24,** 409, 1974) have recently discussed a holographic micro-interferometer, operating at a wavelength of 5320 Å, which measures the optical path length through plasmas at densities exceeding 10^{20} electrons cm^{-3} The duration of their laser pulse 10^{-10} s limits the spatial resolution to 30 μm for plasmas moving with velocities less than 3×10^7 cm s^{-1} Shorter laser wavelengths permit penetration into denser plasmas, and reduce beam deviations caused by refraction at strong density gradients (Thus, the United Kingdom Culham Laboratory is using a 3471-Å holographic interferometer for density measurements with a resolution of 10^{-9} s on sub-kilojoule CO_2 laser-filling experiments) For penetration to densities of interest in the context of laser fusion (10^{25} ~ 10^{27} electrons cm^{-3}) sources of high spectral brightness with wavelengths of less than 10 Å will be needed, there is therefore a considerable incentive to develop coherent X-ray sources for refraction and absorption measurements in this regime

Temperature measurements are also difficult (see Puell *et al*, *Z Naturforsch*, **25a,** 1815, 1970) and at high incident intensities the electron velocity distribution may not be completely Maxwellian For example, at Los Alamos, McCall *et al* (*Appl Phys Lett*, **25,** 108, 1974) have demonstrated a significant departure from equilibrium when a thin polythene (slab) target is irradiated at incident intensities of 10^{16} W cm^{-2} ($\lambda = 1\ 06\ \mu m$) or 10^{14} W cm^{-2} ($\lambda = 10\ 6\ \mu m$) For these measurements a six-channel Bragg crystal spectrometer was used to analyse time-resolved X-ray bremsstrahlung between 4 and 50 KeV with an energy resolution of some 4–12% Conventional scintillator/photomultiplier detectors were used in this work, but for faster detection Key, working with the Garching group, has recently shown that sub-nanosecond X-ray vacuum photodiode detection should be possible Peacock and colleagues have exploited the rich line spectrum emitted from partially ionised $(CH_2)_n$ plasmas, a grazing incidence spectrograph, intensely calibrated over the range 5–45 Å (*J Phys E*, **6,** 854, 1973) is used to unfold line intensities and recombination continua Considerable care is required to achieve reproducible results with such photographic techniques

A wide range of experiments has been reported from laboratories in France, Germany, Japan and the Soviet Union, in which the intensity and spectrum of light back or side-scattered from the target at frequencies near the fundamental laser frequency and its harmonics have been measured, such data should provide valuable information concerning nonlinear absorption mechanisms which are of importance to the concept of laser fusion Within the next decade compression experiments capable of delivering some 1 to 10 kJ of laser energy on to carefully designed targets are planned at KMS, the University of Rochester, Lawrence Livermore Laboratory and Los Alamos in the United States, the Lebedeev Institute in the Soviet Union, and probably at other national laboratories as well The outcome of these experiments will be crucial, since the demonstration of a break-even yield of neutrons would constitute a definitive milestone in the history of thermonuclear research

A new role for the glial cell?

from a Correspondent

GLIAL cells are derived embryologically from the same group of ectodermal cells that gives rise to neurones and they were distinguished from nerve cells more than a century ago by histologists About half the volume of the vertebrate brain is composed of glial cells and these cells outnumber neurones by a factor of roughly 10 to 1 But although glial cells can be studied by morphologists, physiologists know very little about their function It is usually argued that because nerve cells are closely enveloped by glial cells the latter provide a 'supportive function' but just what kind of support has not been clear

A clue that one aspect of this support might be to provide a protein vital for the growth and differentiation of the neurone can be found in the discovery, reported by Longo and Penhoet (*Proc natn Acad Sci, USA*, **71,** 2347, 1974), that a tumour derived from glial cells contains the protein known as nerve growth factor (NGF) The protein was obtained from a rat glioma tumour by the method used to purify NGF from mouse salivary glands It cross reacted with antiserum to mouse NGF, gave similar responses to NGF in two biological assay systems and three of the proteins in the tumour extract had the same isoelectric points as the three fractions of mouse NGF The tumour extract, however, also contained other proteins, as was shown by electrophoresis and bioassay

Nerve growth factor is a basic protein (or class of proteins) which stimulates the growth of embryonic sensory ganglia and whose presence is required for the normal growth and differentiation of peripheral sympathetic noradrenergic neurones The fact that high concentrations of NGF are only found in the submaxillary gland of the mouse and, even there, only after puberty, has long been a puzzle Because animals are uniquely sensitive to the neutralisation of NGF by antiserum during the perinatal period, it has been argued that there must be an important unidentified source of NGF in the newborn animal Longo and Penhoet now suggest that this source may be in the glial cells they put forward the hypothesis that "glia synthesise and secrete NGF which then may act as a 'pleiotypic' stimulant for the neurone"

One of the properties of glial cells—their supportive role during regeneration of damaged nerve axons—is consistent with this hypothesis Noradrenergic neurones in the brain display a remarkable ability to regenerate after damage to their axons Studies in Sweden have shown that NGF injected into the cerebrospinal fluid or directly into the brain close to the locus coeruleus (the site of origin of a major group of central noradrenergic neurones) stimulates this regenerative process (Stenevi *et al*, *Brain Res*, **69,** 217, 1974) This team has also found that intracerebral administration to rats of antiserum to NGF inhibits the regenerative growth of central noradrenergic fibres (Bjerre *et al*, *Brain Res*, **74,** 1, 1974) Since it is believed that NGF does not readily enter the brain from the blood stream, the NGF required for the regenerative process must originate in the brain Could the ubiquitous glial cell be the source of NGF in the central nervous system?

It is to be hoped that the observations of Longo and Penhoet on the presence of NGF in a glioma will lead to attempts to demonstrate NGF in normal glial cells, possibly by the use of immunofluorescence histochemistry If these attempts are successful and if it is possible to demonstrate secretion of NGF from glia, then the glial cells will be recognised as a kind of endocrine tissue that is wrapped around its target cells, the neurones

Oppression or altruism in insect unions?

from our Insect Physiology Correspondent

THERE are differences of opinion among students of bee societies as to the origin and evolution of the worker caste Since the views of Hamilton were put forward in the 1960s, most authors have emphasised the idea of 'kin selection' favouring altruistic social behaviour the workers (the haploid partheno-genetic daughters of the queen) can promote the persistence of genes like their own more effectively by helping their mother to produce more siblings than by leaving home and mating on their own account But some authors favour theories of individual selection Either selection of mothers which can control their offspring, keep them in the nest and suppress their reproductivity, or selection of individuals, which, by their social characteristics of mutual tolerance and continued residence in the nest can benefit both themselves and their mother

Michener and Brothers (*Proc natn Acad Sci USA*, **71**, 671, 1974, *J comp Physiol*, **90**, 129, 1974) have now approached this problem by studying a small eusocial halictid bee *Lasioglossum zephyrum* which burrows in earthen banks Closely related (within the same genus) to solitary species, this bee is about as low in social level as any known eusocial insect, the average membership of a colony is only 14 bees As in other eusocial Hymenoptera, the males play no part in colonial life A large number of experimental colonies, maintained by Lubbock's classic technique, in earth between glass plates, were closely observed and the behaviour of marked individuals was compared and quantified statistically The queens are indistinguishable externally, although they have the largest ovaries, this is only the extreme of a continuum of ovarian size among the workers, the queens are best identified by their behaviour If the queen is removed her place is quickly taken by one of the workers

In her behaviour the queen is characterised by maximum general activity and work on the burrows, a maximum tendency to 'nudge' and disturb other members of the colony and thus to suppress their ovaries, and a maximum tendency (after nudging a bee) to back down the burrow and draw the nudged bee down into the depths of the nest where it will become occupied in constructing and provisioning Queens were also observed to eat the occasional eggs laid by workers Conversely the queen shows minimum activity in pollen collecting, and in guarding the nest, as well as in being nudged, or being induced to follow a backing worker

All this looks far more like oppression of workers by the queen rather than simple altruism by the workers, it suggests that queens have evolved to control their workers rather than that workers have evolved as altruists to help their queens Michener is therefore led to believe that control or 'oppression' by the queen has been of fundamental importance in the most primitive eusocial forms But, as he points out, worker altruism is a necessary consequence of eusocial systems and altruistic behaviour may well be evident sometimes even in the absence of control by the queen

Lassa fever and public health

from Arie J Zuckerman

LASSA fever was first recognised in 1969 and four epidemics have occurred in West Africa since then (*Nature*, **241**, 91, 1973) The severity of the illness is emphasised by a high case fatality ratio of 36–67% among patients admitted to hospital, person-to-person transmission, particularly in the hospital environment, and a high risk of infection to medical personnel To date, 20 medical workers have contracted Lassa fever and nine have died (Monath, *WHO Chronicle*, **28**, 212, 1974) In Africa, the virus was introduced into hospitals by African patients admitted with febrile illnesses which often mimic typhoid fever, malaria or yellow fever Secondary infections occurred among hospital staff and patients, but it seems that although the primary index cases were highly infectious, the secondary cases, for reasons that are not clear, were not

Lassa virus is a member of the arenovirus genus (invariably misspelt arenavirus) The virus is related both morphologically and antigenically to lymphocytic choriomeningitis virus and the viruses of the Tacaribe complex (haemorrhagic fever viruses of South America) A number of the related arenoviruses have been isolated from wild rodents and bats, and although it was postulated that Lassa fever is also a zoonosis, confirmation was not obtained until last month by Monath and colleagues (*Science*, **185**, 263, 1974) During the investigation of the epidemic of Lassa fever in Sierra Leone in 1972 (*Morbidity and Mortality Weekly Report*, **21**, 386, 1972) 641 small vertebrates were trapped Samples of organs and tissues were frozen in liquid nitrogen and sent for study to the Maximum Security Laboratory, Center for Disease Control, Atlanta, Georgia, at present the only laboratory equipped to attempt isolation of this virus safely Lassa virus was isolated from a single murine species, the multimammate rat *Mastomys natalensis*, which is a common commensal rodent in West Africa adapted to life both within houses and in the fields It is of interest that rodents of other species commonly found in the area of the epidemic in Sierra Leone (*Mus musculus* and *Rattus rattus*) were not infected, and it seems that these species either resist infection or avoid contact with infected *Mastomys*

The mode of transmission of the virus from rodent to man or from man to man is not known yet Similarly, the pathogenesis of Lassa virus infection in its natural host remains unknown It is, however, reasonable to expect that perhaps like a number of other arenoviruses, which induce a chronic virus carrier state in their natural hosts, for example lymphocytic choriomeningitis, a persistent infection with Lassa virus develops and both horizontal and vertical transmissions occur Rodents may excrete the virus in urine and saliva and may thus contaminate food, water or the air Monath *et al* suggest that the low level of sanitation, the storage of grain and food within houses and the ease with which rodents infest mud and thatch houses enhance the contact between rodents and man The means by which the virus is spread from person to person is not clear Medical attendants or relatives providing direct personal care are most likely to contract the infection Accidental inoculation with a sharp instrument or contact with blood has accounted for a few cases (see *Nature*, **241**, 91, 1973) Lassa virus has been isolated from the pharynx and urine of patients so that indirect airborne spread of the virus as well as mechanical transmission are most likely

Serological and epidemiological investigations have shown that Lassa fever seems to be limited to West Africa, and there is evidence that the virus was present in the Republic of Guinea in 1952, within the last two years it reached Senegal Mild and perhaps subclinical infections are now recognised to be not uncommon outside the hospital environment In the absence of a vaccine, available methods of control of community outbreaks are rodent control and quarantine. It has been pointed out previously, however, that the epidemiological propensities of Lassa fever may be very wide as a

SCIENCE COLLEGE

result of fast air travel Indeed, a number of cases have been treated in a London hospital Monath (*WHO Chronicle*, **28**, 212, 1974) wrote that a programme of surveillance must be instituted both in West Africa and in the developed countries To this one should add the provision of hospital isolation and laboratory facilities in selected centres

Sicily as part of Africa

from Peter J Smith

ACCORDING to Barberi *et al* (*J geophys Res*, **78**, 5221, 1973), the southern Tyrrhenian Sea contains an island arc structure which includes a sediment filled trench along the Ionian coast of Calabria, a metamorphic belt stretching along Calabria into Sicily, a calc–alkaline volcanic arc in an advanced state of evolution (Eolian Islands) and a back-arc marginal basin (Tyrrhenian Abyssal Plain) In short, the Tyrrhenian Sea area is readily interpreted in the light of the destructive boundary between the African and European plates But where precisely does the plate boundary lie in this region? McKenzie (*Geophys J*, **30**, 109, 1972) and several other workers have proposed that the boundary line actually crosses northern Sicily, in which case most of Sicily will be a part of the African plate New evidence in favour of this view has now come from two quite different sources

Evidence adduced by Barberi *et al* (*Earth planet Sci Lett*, **22**, 123, 1974) comes from the distribution, age, nature and palaeomagnetism of volcanic rocks in the east of the island, although the volcanics are only one of five principal provinces in Sicily In the extreme south-east lies the Ragusa–Iblei carbonate platform which is not affected by Alpine folding and seems to be an extension of the Sahara platform In other words, the southernmost part of Sicily is apparently linked geologically with Africa—a view supported by the existence of 20 km-thick continental type crust to the south of the island Central and western Sicily comprise a Mio–Pliocene resedimentation basin, and in the north there is a series of flysch nappes ranging in age from Cretaceous to Miocene But the extreme north-east of the island is a crystalline massif forming the continuation of the Calabrian metamorphic belt In other words, the northernmost part of Sicily is apparently linked geologically with Europe The view that the Euro–African plate boundary crosses Sicily is thus supported in general terms by the geology

For a more quantitative picture of Sicily's behaviour, however, it is necessary to look at the eastern part, which has been a site of dominantly basaltic volcanism since the middle Triassic (although only Cretaceous and younger rocks are exposed) The most recent episodes of (subaerial) volcanism are represented by Mt Etna and Mt Iblei, but all volcanic activity before this was submarine, giving rise to pillow lavas and hyaloclastics emitted through fissures in a carbonate platform The oldest rocks examined palaeomagnetically by Barberi and his colleagues were Upper Cretaceous dykes (with potassium-argon ages in the range 71–84 million years) cutting hyaloclastics of three different Cretaceous outcrops From Cretaceous to Upper Miocene no basaltic volcanism occurred in the region, although important activity has occurred since, principally in the vicinity of Iblei and Etna The second set of rocks studied was therefore of Iblei volcanics within the age range 1 7–5 4 million years

The palaeomagnetic results are simply stated The Upper Cretaceous pole is consistent with that for Africa obtained by Shazly and Krs (*Geol Rdsch*, **62**, 212, 1973) but significantly different from the mean Cretaceous pole for Europe The Plio–Pleistocene pole for Sicily is consistent with the mean Upper Tertiary–Quaternary poles for the Central European-Russian platform and for the French Massif Central lavas and with the Quaternary poles for Africa and Spain (Gerona volcanics) It thus seems that there has been no significant motion of eastern Sicily with respect to Africa since the Cretaceous On the other hand, Sicily has moved with respect to Europe since the Cretaceous, but not since the end of the Miocene The implication, therefore, is that (with the probable exception of the extreme northeast of the island) Sicily has been part of the African plate since the Cretaceous—and thus in all likelihood since at least the Triassic

Barberi and his colleagues then visualise Sicily's fitting into the evolutionary pattern of the region in the following way From the Upper Triassic to the Upper Cretaceous the African plate moved south-easterly with a sinistral shear movement with respect to Europe, resulting in a separation of the African and European plates and the formation of oceanic crust The northern edge of the African plate (and thus Sicily) then underwent distension—a process consistent with the alkalic products of volcanism observed in Sicily for the relevant period From the Upper Cretaceous to the present the motion of Africa with respect to Europe has been mainly compressional with minor dextral movement—a change also reflected in Sicilian volcanism Basaltic distensive volcanism was absent from eastern Sicily from the Upper Cretaceous to the Upper Miocene The occurrence of Upper Oligocene–Lower Miocene andesitic volcanism suggests, however, that the compression between Africa and Europe was accompanied by subduction of the oceanic crust previously formed between Sicily and Europe, a process which gave rise to island arc type volcanism towards the end of the Oligocene Crustal consumption lasted until the Lower Miocene, when the continental collision occurred, and since the late Miocene Sicily has been joined to Europe, as the Iblei palaeomagnetic data indicate

An obvious problem with this scheme is the post Miocene and current basaltic distensive volcanism in eastern Sicily, which is difficult to explain in terms of the general tectonic framework of compression The explanation put forward by Barberi *et al* is that continental collision has occurred at different points along the Sicilian-Calabrian segment of the plate boundary at different times, possibly because of the irregular shapes of the encroaching continents For example, the subduction of oceanic crust beneath the Calabrian arc is still active (hence the Eolian island arc), although the continental nature of the crust on both sides of the boundary suggests that crustal consumption is now nearly complete In any event, since the Lower Miocene eastern Sicily has been the border zone between colliding continental blocks and the oceanic lithosphere subducting beneath the Calabrian arc, and has thus probably been affected by local distension, notwithstanding the general overall compression

The second piece of evidence supporting the view of Sicily as part of Africa comes from laser geodimeter measurements between the island and Calabria on the Italian mainland Caputo *et al* (*Geophys J*, **38**, 1, 1974) report six sets of such measurements made between September 1970 and September 1973 Needless to say, even with lasers it is a difficult task to determine the very small distance changes likely to be involved over such a short period, and the variations in the lengths of the sides of the Sicily-Calabria geometric net are indeed found to be generally smaller than the measurement errors and data corrections Nevertheless, Caputo and his colleagues tentatively conclude that a statistically significant displacement between Sicily and Calabria took place between September 1970 and June 1971 During this period (but not subsequently) Sicily was displaced roughly northward with respect to the mainland, implying that it participates in the movements of Africa rather than Europe

Harmony of the spheres

from Robert W Cahn

VERY gingerly, the proponents of fibre reinforcement are beginning to approach the serious possibility of using fibre-reinforced materials for service at high temperatures—for instance, in gas turbine components One central difficulty about this is that the metallic matrix may chemically attack the fibres, for example, tungsten fibres interact chemically in a complicated way with a nickel matrix The other tricky problem is to keep the shapes of the fibres inviolate It is not too difficult to generate a regularly spaced array of long, thin fibres in a suitable matrix, much research has been done on the directional growth of monocrystals of appropriate binary and ternary alloys, consisting of aligned fibres (or plates) in a matrix The trouble is that a long thin cylindrical fibre is not in geometrical equilibrium with its matrix

In a slowly grown eutectic, the total quantity of fibrous phase will be in equilibrium with the total quantity of matrix the disequilibrium is purely a matter of geometry This has long been known to metallurgists familiar with ordinary mild steel The pearlite ($Fe+Fe_3C$) eutectoid lamellae, if sufficiently heated, turn into arrays of fine Fe_3C spheres The process, spheroidisation, is driven purely by the tendency to minimise the total area of Fe/Fe_3C interface The same can happen to a long fibre in a matrix

As so often in physical science, one of the key ideas comes from Lord Rayleigh In 1878 he showed that a cylindrical jet of water tends to instability it is apt to pinch off at intervals of about eight diameters Recently, McLean of the National Physical Laboratory, showed (*Phil Mag*, **27**, 1253, 1973) that, correspondingly, cylindrical inclusions of lead in aluminium split into separate short cylinders if the aspect ratio (length/diameter) exceeds 8 Each cylinder then gathers up into a sphere The relevance to the stability of a population of fibres is manifest Although aluminium–lead is no candidate for high temperature use, it is a useful model system

With the collaboration of Loveday, McLean (*J Mater Sci*, **9**, 1104, 1974) has now taken his investigation of Al/Pb alloys a long step forward The main improvement is one of technique instead of using X-ray microradiography between anneals, the investigators examined their foils in a 1-MeV electron microscope fitted with a heating stage With the aid of cinematography, and exploiting the high penetrating power of the energetic electron beam, the investigators were able to trace in detail the stages of spheroidisation and make accurate kinetic measurements In addition to the advantages of *in situ* micrography, they also achieved a much higher resolution by this technique

Correction

In the News and Views article "Bugs are Beautiful" (**250**, 533, 1974), the abbreviation AISB stands for Artificial Intelligence and Stimulation of Behaviour Group, the published explanation is incorrect

The lead inclusions in the Al+5wt% Pb alloy were turned into cylinders by mechanical swaging (there is no suitable eutectic) and foils cut from this material were heated in the microscope to above the melting temperature of the lead The spheroidisation process is governed by diffusion of matrix atoms through the cylinders, since the lead was molten diffusion was rapid and so was the spheroidisation The cylinders either broke up into shorter ones which then turned into spheres or short cylinders spheroidised directly, Rayleigh's criterion was approximately obeyed The detailed observations allowed the diffusivity of aluminium in molten lead to be determined for a range of temperatures

McLean and Loveday were also able to examine the merging of individual spheres once they had formed The lead spheres behaved just like the bubbles of helium in nuclear fuels which have been extensively investigated in recent years, migrating under the driving force merely of a temperature gradient The kinetics of merging of large bubbles (diameter $\sim$1 μm) was studied and found, again, to be controlled by volume diffusion of aluminium in liquid lead These large bubbles moved at a speed, independent of their size, which was consistent with the estimated temperature gradient in the microscope hot stage Bubbles with diameter less than 0 8 μm moved more slowly the smaller the bubble, this is proof positive that the motion of these small bubbles was controlled by interface energy and not by volume diffusion Very small bubbles, less than 0 12 μm in diameter, did not move at all This immobility is a new phenomenon and its origin is not clear

The observations showed the merging of pairs of large bubbles when one catches up another, and the kinetics of this process were consistent with the theory developed by earlier investigators of bubbles in nuclear fuels It seems that bubbles behave in the same way irrespective of whether they are filled with gas or with molten metal

McLean and Loveday point out that their observations have practical implications (quite apart from their relevance to the stability of composites) Free-machining alloys such as leaded brass contain small particles of soft metal in a hard alloy matrix, and it should now be possible to develop a prescription for a combined mechanical/thermal treatment to produce form of spherical dispersion with the best machining characteristics

Light from QSOs

from a Correspondent

THE QSOs—the quasi-stellar objects, or quasars—are believed by many astronomers to be remote galaxies that radiate extraordinarily large amounts of energy as a result of some violent explosion in the galactic nucleus In all probability the source of energy is gravitation, but the process whereby some of that energy is converted into visible radiation is ill-understood Although the total flux may be thousands of times greater than in a normal 'quiet' galaxy, the size of the source region must be quite small, no more than a few light days, since fluctuations in light intensity have been observed over a few days, and with a larger source they would be smeared out The investigation of possible radiation mechanisms is therefore an important task in contemporary astrophysics, and the suggestions put forward by Colvin (*Astrophys J*, **190**, 515, 1974) are of considerable interest

The popular approach, adopted by nearly all theorists, supposes that the explosive event produces a relatively dense plasma in the radiating volume (perhaps 10^8 or more ionised atoms per cm^3), a strong magnetic field linked to the plasma, and high energy relativistic electrons These are certainly the ingredients involved in producing radiation from supernova remnants like the Crab nebula, and it is attractive to try using them again with the QSOs Indeed, the most straightforward hypothesis is that the observed radiation from the QSOs, like that from the Crab nebula, is the synchrotron radiation produced by the spiralling of relativistic electrons round the magnetic field lines The relativistic electrons act as a link in the chain of energy flow energy comes to them from the explosive event and is reradiated by them as synchrotron radiation

Unfortunately, difficulties appear on a closer examination The observed spectral distribution of the radiation does not conform very well with that expected for synchrotron radiation, and in the physical conditions of a OSO one could expect the relativistic electrons to lose energy more readily through the inverse Compton process The inverse Compton process can be pictured as radiation by the electrons on account of their acceleration in the electric fields of the electromagnetic radiation through which they move, whereas synchrotron radiation is caused by the acceleration associated with spiralling round quasi-static magnetic field lines Large magnetic fields, considerably in excess of 100 gauss, are needed to ensure that the synchrotron process is dominant, and such fields are not easy to come by with some models of the 'explosive event' What Colvin has done is to suggest a two-stage process for generating the radiation from QSOs that is effective even with magnetic fields as small as 30 gauss

The basic fact made use of in the theory is that for some radiation frequencies a plasma containing a magnetic field has a refractive index greater than 1 Highly relativistic particles particles therefore move through it at a speed exceeding the speed of light in the medium In consequence they produce Čerenkov radiation—the electromagnetic equivalent of the shock wave generated in air by supersonic aircraft Colvin estimates that under QSO conditions the Čerenkov photons could have a characteristic frequency of 10^8 Hz The number of photons could be sufficient for them to make the relativistic electrons of lower energy then undergo inverse Compton energy loss and produce visible radiation of the intensity that is observed

Strength functions in rare earths

from P E Hodgson

According to the simple single-particle model of nuclei each nucleon occupies a state with definite energy and quantum numbers, and these are the eigenstates of a one-body potential Such states are selectively populated by one-nucleon transfer reactions, and a study of these reactions enables the energies of the single-particle states to be determined

Thus, for example, a (d,p) reaction simply puts a neutron into one of the unoccupied single-particle states of the residual nucleus, so that the energy spectrum of the emitted protons reflects the energies of the unoccupied states in the residual nucleus

In practice such a simple result is only found even approximately for the low-lying states in reactions depositing a nucleon into a closed shell nucleus In other cases the single-particle strength is distributed over a range of excitation energies This takes place in two different ways, either the single-particle strength can be 'spread' over a large number of states in the residual nucleus according to a Lorentzian distribution or it can be 'fragmented' by residual interactions that are not taken into account by the one-body potential The latter can result from a coupling of the single-particle states to vibrational degrees of freedom or from coupling between the one and three quasiparticle states The spreading width is expected to increase with excitation energy while the fragmentation width remains almost constant

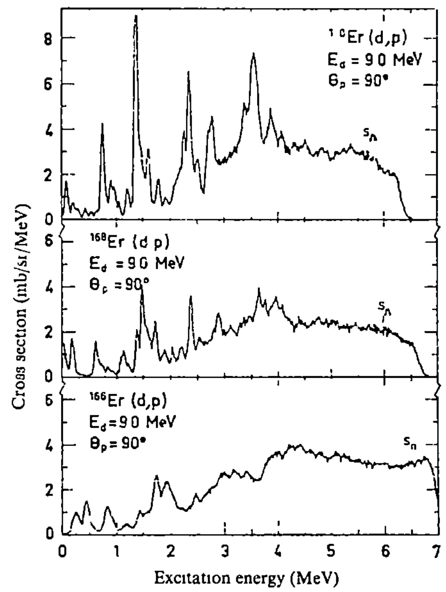

Fig 1 Energy spectrum for the (d,p) reaction at 9 MeV on three isotopes of erbium

It is important to try to find out the relative importance of spreading and fragmentation, for only if the fragmentation is less than the spreading is it possible to identify and assign quantum numbers to the higher states

This problem has recently been studied in the rare earth region by Back, Bang, Bjørnholm, Hattula, Kleinheinz and Lien (*Nucl Phys*, **A222,** 377, 1974) They irradiated several isotopes of the rare earth nuclei gadolinium, dysprosium, erbium and ytterbium with 9 MeV deuterons and measured the energy distribution of the outgoing protons Plotted on an appropriate energy scale this gives immediately a measure of the distribution of the neutron single-particle strength, or neutron strength function as it is called A typical result, that for erbium, is shown in Fig 1, the peaks in the spectra move towards lower energies for the heavier nuclei, which is what would be expected from the Nilsson model, and that there is structure below about 4 MeV but no structure at higher energies

The theoretical cross sections for these reactions were calculated using the distorted wave theory of stripping reactions to single particle states in deformed nuclei The wavefunctions were calculated as the eigenvalues of a deformed Saxon–Woods potential To enable the results of this calculation to be compared with the data the peaks were broadened by multiplying by a Lorentz factor The results for erbium are shown in Fig 2*a* and show qualitative agreement The cumulative cross section (Fig 2*b*) is in good accord with the data, indicating that the total neutron strength is preserved and that higher order processes are relatively unimportant It is, however, difficult to make unique quantum number assignments to the peaks at higher energies

This work gives a remarkably clear picture of the behaviour of neutron single-particle strengths as a function of excitation energy, and shows that both spreading and fragmentation take place

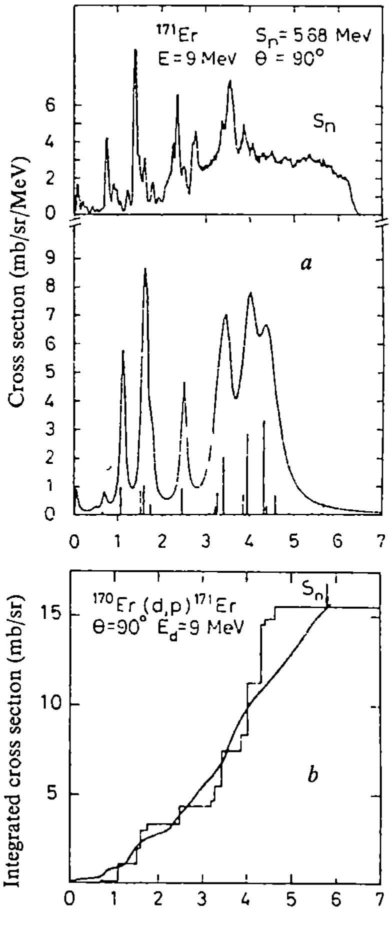

Fig 2 *a*, Experimental (upper) and theoretical (lower) differential cross sections calculated in a deformed Saxon–Woods potential The vertical lines represent the total stripping strength of the rotational band corresponding to the deformed single-particle state The smooth curve represents this strength distributed according to the Lorentz factor *b*, Comparison of the cumulative integrated experimental cross section and the theoretical cross section for energies below the neutron separation energy S_n

Biological significance of the intermolecular crosslinks of collagen

A. J. Bailey, S. P. Robins & G. Balian

Agricultural Research Council, Meat Research Institute and Department of Animal Husbandry, University of Bristol, Langford, Bristol, UK

Current theories of the crosslinks stabilising the collagen fibre are based on the isolation of compounds from borohydride-reduced collagen What is the evidence for their existence in vivo *and what, if any, is the physiological significance of these proposed crosslinks both in normal and pathological conditions?*

THE recent advances in the biochemistry of collagen are due in part to its ubiquitous nature, as it exists in various forms specifically tailored to the particular function of each body tissue, and in part from the realisation that it is not completely metabolically inert but plays an important role in connective tissue disorders

The special properties that enable collagen to act as the major supporting framework of the body are largely dependent on the high structural stability of the collagen fibres Collagen fulfils this function by means of its unique molecular configuration, the highly specific alignment of the molecules during extracellular aggregation and finally by the formation of covalent crosslinks[1,2] The latter are particularly important in conferring on the fibres the high tensile strength and resistance to chemical attack necessary for their function A malfunction, genetic or otherwise, in any one of the complex sequence of events leading to the formation of the final crosslinked fibre could result in an impairment of the fibre strength There are a number of connective tissue diseases in which the clinical symptoms suggest a crosslinking defect Furthermore, the extent of crosslinking may be important in affecting the catabolic rate in the more common conditions involving fibrosis and degeneration

The initial stage in the formation of the intermolecular bonds is the oxidative deamination of specific lysine or hydroxylysine residues located in the nonhelical regions at both the N- and C-terminals of the molecules by a copper-dependent enzyme, lysyloxidase[2] The aldehydes produced are then believed to condense with reactive groups, predominantly the ε-amino groups of hydroxylysine, situated in the helical region of neighbouring molecules thus forming a network of intermolecular bonds which were assumed to be of the aldimine type[3-5] The lability of the aldimine bonds precluded the direct investigation of the compounds and the technique of mild reduction of the fibres with borohydride was therefore used to render the crosslinks stable to the hydrolytic procedures necessary for their isolation All of the major reduced components present in borohydride-treated collagen have now been characterised and from the known action of borohydride, assumptions were made as to the form of these components that are present in the native fibre

Early studies using radioactively-labelled lysine and lathyritic agents such as β-aminopropionitrile and α-amino β-thiols indicated that the reducible compounds were derived from lysine-aldehydes and were therefore implicated in the intermolecular crosslinking process[6] Despite these indications, however, the identification of compounds, or even crosslinked peptides containing these compounds, from borohydride reduced collagen does not constitute proof that their nonreduced forms act as intermolecular bonds *in vivo* since the initial condensation reaction could have been promoted by the alkaline reducing conditions

Our aim here, therefore, is to review critically the components isolated from borohydride-reduced collagen in relation to the physiological role of their nonreduced forms in the fibre The influence of these compounds on the physical properties of the fibre will be considered particularly regarding the changes that occur with age, and in pathological conditions

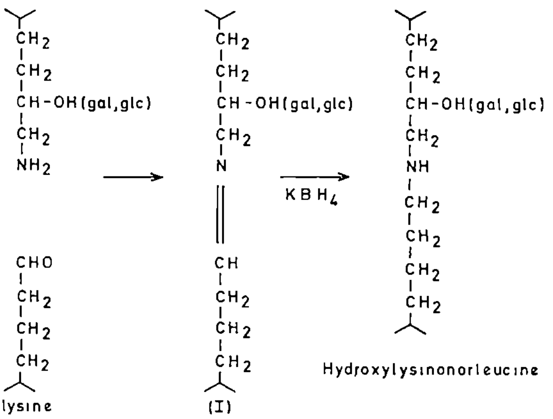

Fig 1 Biosynthesis of dehydro-hydroxylysinonorleucine (I)

Components of reduced collagen

Hydroxylysinonorleucine. This compond was the first reduced component, believed to represent a reduced intermolecular crosslink, to be isolated and characterised[7] Its presence in reduced fibres but not in solutions of monomeric collagens, and the lability of the native fibre to dilute acids, heat, and α-amino β-thiols, indicated that the nonreduced form existed as a labile intermolecular crosslink[8] Subsequent characterisation after isolation from borohydride-

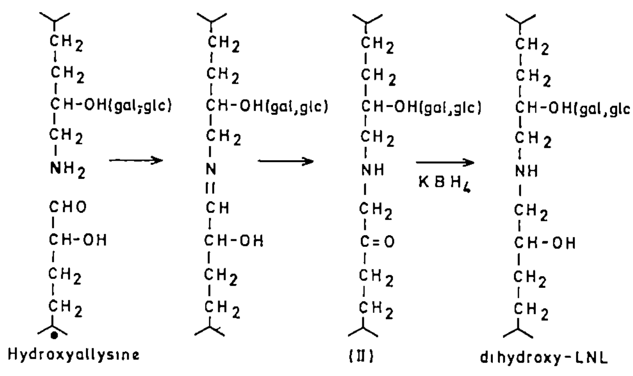

Fig. 2 Biosynthesis of hydroxylysino-5-keto-norleucine (II)

reduced native collagen was consistent with its proposed derivation from the aldimine bond form[7] (Fig 1) Unfortunately, the lability of the nonreduced form of the compound precludes the isolation of a crosslinked H-peptide from skin collagen to confirm its existence *in vivo* However, when derived from hydroxyallysine and lysine the bond is stabilised by undergoing the Amadori rearrangement (see below) It is therefore possible to demonstrate its existence *in vivo* by isolation from bone or cartilage collagen (unpublished data)

Recently, both galactosyl and glucosyl-galactosyl deriva-derivatives of the crosslink have been characterised after their isolation from alkaline hydrolysates of borohydride-reduced collagens[9] The relative proportions of the mono- and disaccharide crosslinks varies with different tissues as does the total extent of glycosylation The attachment of hexose does not seem to have a significant effect on the stability of the aldimine bond, but may facilitate aldimine bond formation by lowering the *p*K of the ε-NH$_2$ group

Hydroxylysinohydroxynorleucine. This compound designated syndesinol was reported to be a major component of borohydride-reduced tendon, bone and cartilage but was misidentified as an aldol derived from hydroxyallysine[10] Later studies by mass spectrometry indicated that it was a reduced aldimine derived from hydroxylysine[11,12] and this structure was confirmed by chemical synthesis[12] But the assumption that this compound exists *in vivo* as an aldimine was inconsistent with its unusual stability to heat, dilute acids and D-penicillamine[6,15] It was therefore proposed that migration of the double bond could take place to form the stable keto form by undergoing a spontaneous Amadori rearrangement[14] This proposal was confirmed by a Smith degradation of the reduced compound[15] isolated from bone the tritium activity was found to be associated almost exclusively with the proline and hydroxynorvaline produced, thus indicating that the rearrangement must have been complete Further studies have shown that the rearrangement is also complete in tendon and embryonic skin The crosslink must therefore exist *in vivo* as hydroxylysino-5-keto norleucine (Fig 2)

In common with the monohydroxy crosslink, glycosylated derivatives of di-hydroxylysinonorleucine are present in varying proportions with different tissues[9,16] Since the crosslink exists completely in the keto form in the native fibre, clearly the carbohydrate moeity can only be attached to the remaining hydroxyl group of the hydroxylysine residue from the helical body of the molecule

The stability of this crosslink suggested that it might be possible to isolate a crosslinked peptide from nonreduced cartilage collagen as described by Miller[17] for the isolation of the corresponding peptide from borohydride reduced fibres The peptide isolated gave an amino acid analysis consistent with a crosslinked dipeptide of α 1(II) CB4 and CB9, and on reduction revealed the presence of dihydroxylysinonoleucine[18] Periodate cleavage and subsequent reduction of the reduced H-peptide produced two peptides with analyses consistent with CB4 and CB9 Alkaline hydrolysis of the peptide indicated that about 20% of the crosslink was present as the glucosyl-galactosyl derivative

The isolation of a crosslinked peptide from nonreduced collagen provides further evidence that this hydroxy-allysine derived component does exist *in vivo* acting as an intermolecular crosslink between two adjacent collagen molecules From the order of the CNBr peptides of cartilage collagen α 1(II) chains determined by Miller[19] it is obvious that the crosslink occurs between the N-terminal telopeptide and a hydroxylysine residue in the helical region of the molecule such that the two molecules are overlapped as predicted by Hodge and Petruska[20]

It is conceivable that the acid conditions of the CNBr cleavage catalysed the Amadori rearrangements of the aldimine bond and hence, that the isolation of a peptide containing the crosslink in the keto form is not proof of its existence in the native fibre But the previous experiment in which the native fibre was reduced under alkaline conditions confirmed that the crosslink exists entirely in the keto form Thus, taken together these two experiments provide direct proof that hydroxylysino-5-keto-norleucine acts as an intermolecular crosslink in the collagen fibre under physiological conditions

Histidino-hydroxymerodesmosine. This component, present in high proportions in borohydride-reduced skin and tendon[6], has recently been shown to have a structure capable of linking three or four peptide chains[21] The component isolated is presumed to be formed by the Michael addition of histidine to the α,β-unsaturated double bond of the intramolecular aldol, and subsequent condensation of the aldehyde moiety of the aldol with hydroxylysine, the aldimine formed is stabilised by borohydride reduction thus permitting isolation of the compound (Fig 3)

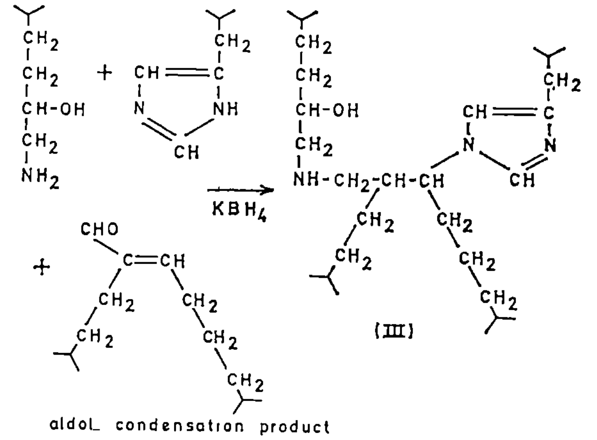

Fig 3 Formation of histidino-hydroxymerodesmosine (III)

Based on the structure of this compound, histidino-hydroxymerodesmosine, it was proposed that the compound existed before reduction as the aldimine bond form[21] Direct confirmation by the isolation of a crosslinked peptide is not possible owing to the extreme lability of the nonreduced form Indeed, it was these earlier studies on the stability of the presumed crosslink in native fibres that called into question the existence of this complex component under physiological conditions[15,22] In particular, fibres pretreated with acid phosphate not only failed to form histidino-hydroxymerodesmosine on borohydride reduction but also resulted in a concomitant increase in the amount of the reduced intramolecular aldol The proportion of the dehydro-hydroxylysinonorleucine was unaffected under these conditions These results imply that cleavage has occurred of both the aldimine bond and the Michael addition product

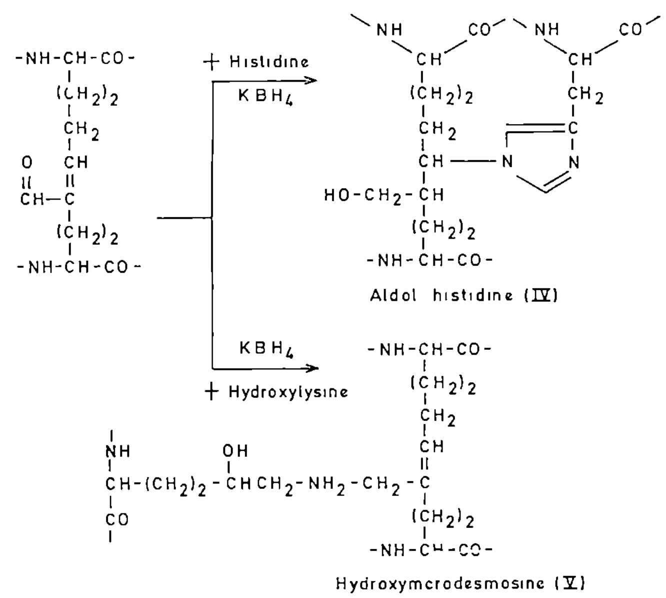

Fig 4 Formation of aldo histidine (IV) and hydroxymero desmosine (V)

But, unlike the aldimine bond linking the hydroxylysine residue, the Michael adduct forms a covalent bond which is not stabilised on reduction with borohydride but is a stable entity *per se,* as evidenced by the resistance of the histidine-aldol bond to cleavage by acid or base hydrolysis during its isolation

The most likely explanation is that the Michael addition does not occur under physiological conditions but is a base-catalysed reaction brought about during reduction with borohydride[22] Any disruption of the precise three-dimensional arrangement of the molecules in the fibre (such as freeze-drying) was found to partially inhibit the formation of this compound on borohydride reduction Thus, although it is conceivable that some noncovalent stabilisation (for example, hydrogen bonding as occurs in the active site of some enzymes[23,24]) may be derived from the adjacent functional groups in the native fibre, the results suggest that the proposed nonreduced aldimine form of histidino-hydroxymerodesmosine does not exist as an intermolecular crosslink *in vivo*

Minor reducible components

Lysinonorleucine The small amounts of this compound in reduced native collagen[25,26] probably reflect incomplete hydroxylation of the lysine residues in the helical portion of the molecule that participate in aldimine bond formation Indeed, when hydroxylation of the lysines is partially inhibited, as in vitamin C deficiency, then a higher proportion of this component is present[27] It is unlikely that the presence of such small amounts of this crosslink makes a significant contribution to the stability of the collagen fibre

Aldol-histidine and hydroxymerodesmosine These two reduced components have been isolated in small amounts and have been proposed as intermediates in the formation of histidino-hydroxymerodesmosine[28,29] (Fig 4) Since the Michael addition of histidine to the aldol is believed to be promoted by borohyde it is probable that aldol-histidine is also an artefact In view of the apparent instability of the nonreduced form of hydroxymerodesmosine and its possible conversion to the histidine derivative on reduction the rôle of this crosslink is difficult to assess, but the effect of the small proportion detectable is likely to be minimal

Hexosyl-lysine and hexosyl-hydroxylysine. The characterisation of these reducible components[30,31] which are present only as minor constituents in young tissue but which apparently increase with age demonstrated that they are derived from the condensations of lysine and hydroxylysine with glucose and mannose (Fig 5) Their structure clearly indicates that these compounds can neither be involved in collagen crosslinking nor can they bind collagen to glycoprotein since in the latter no reducing group is available for the condensation reaction Although the presence of these compounds might indicate a progressive increase with age in the binding of polysaccharides to collagen, the physiological implications, if any, of these observations are as yet unknown

Tissue differences

From the foregoing discussion it is apparent that of the components isolated from reduced collagen of young tissues, only hydroxylysinonorleucine and dihydroxylysinonorleucine are derived from intermolecular crosslinks present *in vivo* in significant amounts Clearly, the type of crosslink formed is governed by the extent of hydroxylation of the lysine residues in the N- and C-terminal nonhelical regions In skin these residues are not hydroxylated[32-34] leading to the formation of dehydro-hydroxylysinonorleucine whereas in bone and cartilage hydroxylation is virtually complete[35,36] resulting in the formation of hydroxylysino-5-keto-norleucine In tendon collagen, the lysine is about 50% hydroxylated giving rise to both these crosslinks in roughly equivalent amounts

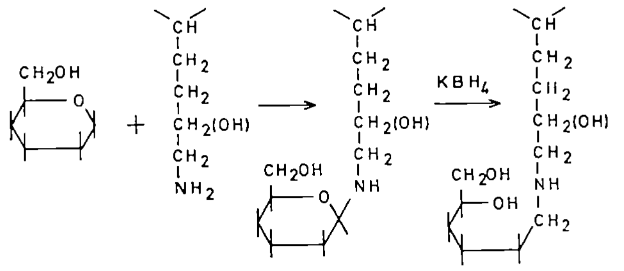

Fig 5 Formation of hexosyl-lysines and -hydroxylysines

The influence of these different crosslinks on the properties of the tissue should be reviewed in the context of their physiological function In the absence of the lysine-derived aldehydes in both experimentally induced lathyrism and copper deficiency, the collagen fibres have very little tensile strength and are completely soluble in neutral salt buffers[2] The formation of the intermolecular covalent crosslinks provides a high tensile strength to the fibre but this does not necessarily render the collagen insoluble Thus the aldimine component, dehydro-hydroxylysinonorleucine, provides a high tensile strength to rat tail tendons but the fibres are completely soluble in dilute acetic acid owing to the chemical lability of this bond For skin collagen this crosslink can account, at least in part, for the tensile strength but not for the high proportion of insoluble collagen By contrast, in the highly insoluble collagens such as bone and cartilage, the major reducible intermolecular bond *in vivo* is the stable crosslink, hydroxylysino-5-keto-norleucine, and its presence could therefore account for the insolubility of these tissues Similarly embryonic skin[37] and granulation tissue[38] possess a high proportion of this crosslink and contain very insoluble collagens But the possibility cannot be ruled out that other factors such as the presence of glycosaminoglycans may contribute to the solubility of these types of collagen

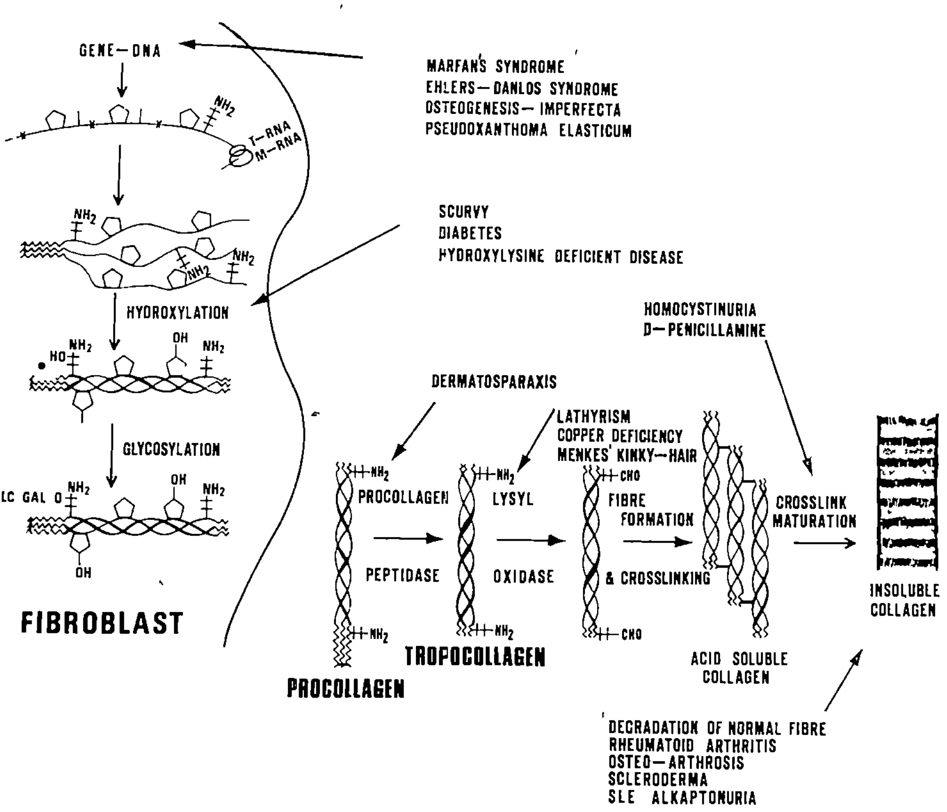

Fig 6 Schematic representation of the series of reactions in the biosynthesis of the interstitial collagen fibres depicting the possible stages at which defects could occur resulting in genetic disorders The dominantly inherited disorders, Marfans syndrome, Ehlers–Danlos Syndrome, osteogenesis imperfecta and pseudoxanthama elasticum suggest a primary structure defect[43] Scurvy results from a vitamin C deficiency leading to inefficient hydroxylation[37] Diabetes has been reported to result in excess hydroxylation[38] Hydroxylysine deficient disease is due to the absence of lysyl hydroxylase[45] Dermatosparaxis results from from the absence of procollagen peptidase[47,48], lathyrism is due to inhibition of lysyl oxidase[21] and Menkes kinky hair syndrome to copper deficiency[50], an essential cofactor of lysyl oxidase[2] Homocystine[59] and D-penicillamine act by cleavage of the labile aldimine crosslink

and any proposed relationship between the nature of the crosslink and solubility must, in the absence of further experimental evidence, remain unconfirmed As discussed below, the reducible crosslinks are known to decrease with age and it is important to emphasise that these observations only apply to young growing tissue

Age-related changes

It is well known that with increasing age collagenous tissues become increasingly more stable to external influences[39] For soft tissues such as skin, there is a progressive decrease in the amount of collagen extractable by acetic acid, a fact that is incompatible with the presence solely of the labile aldimine type of intermolecular bonds Studies of the reducible components present in tissues covering a wide range of ages showed that no new compounds other than the hexosyl-lysine derivatives are formed during the ageing process The variations with age in the proportions of the reducible crosslinks were found to parallel the rate of growth[14] Thus, there is an initial rapid rise in their amounts during the laying down of new collagen but this is followed by a gradual decrease so that at maturity the reducible crosslinks are virtually absent It is during this latter period that the collagen fibres become increasingly insoluble whilst retaining their tensile strength To account for these facts it was proposed that the reducible crosslinks act only as intermediates and are converted during the maturation process into a nonreducible and, certainly in the case of the aldimine type compound, a more stable form

One possible modification of the crosslinks that could account for the observed results is by reduction *in vivo* to form compounds identical to those produced by the borohydride treatment Such a reaction is known to occur in elastin, resulting in the formation of lysinonorleucine from its aldimine form[40] but a similar analysis of old nonreduced collagen failed to reveal any *in vivo* reduced forms[25] Later, Mechanic *et al*[41] proposed from mass spectral data that some 25 to 50% of the intermediate crosslinks in bone and dentine collagen are reduced *in vivo* and supporting evidence was derived from the *in vitro* ageing studies of Deshmukh and Nimni[42] A more recent study[14] using several different techniques has, however, confirmed the earlier report that reduction *in vivo* of the intermolecular bonds does not occur in collagen Thus the nature of the stable crosslinks present in the insoluble mature tissue remain to be elucidated, although based on the evidence now available the most likely explanation is that these stable bonds are derived in some way from the reducible crosslinks Hence, it is not necessary to propose a continuous increase in the number of crosslinks, with all the attendant difficulties of enzyme reactions within the fibre rather a spontaneous conversion of the reducible intermediates to the stable mature form would account for the observed facts

Collagen diseases

A number of heritable connective tissue disorders suggest, at least from the clinical symptoms, that the disorder might be a defect in the crosslinking mechanism (Fig 6) The Ehlers–Danlos[43, 44] syndrome in which the skin is hyperextensible, the Marfans[43] syndrome in which the aorta frequently ruptures, and osteogenesis imperfecta[43] in which the bones are extremely brittle, all strongly suggest that the disorders could be defined in terms of the molecular biology of collagen

Such definitions have recently been achieved with some recessively inherited disorders In a type of Ehlers–Danlos syndrome (Type VI) the defect was shown to be an absence of lysyl hydroxylase resulting in a collagen deficient in hydroxylysine[45] Since hydroxylysine is an essential component of all the collagen crosslinks so far identified it is not surprising that there was a consequent lack of crosslinking[46] consistent with the clinically observed tissue fragility Another enzyme deficiency occurs in Ehlers–Danlos type VII in which the low level of the procollagen peptidase activity results in the presence of procollagen during fibre formation[47] The defect may be a milder form of dermatosparaxis described in cattle in which the presence of the extra nonhelical regions disorganises fibre formation resulting in inefficient crosslinking and hence a fragile fibre[48,49] The disruption and fragmentation of the large arteries in Menkes kinky hair syndrome is probably due to the low intestinal absorption of copper[50] the absence of which is known to lead directly to inhibition of crosslinking in both collagen and elastin[51]

Although some success has been achieved with the recessively inherited disorders, the basic defect in the dominantly inherited disorders, Ehlers–Danlos, Marfans and osteogenesis imperfecta, is less forthcoming. Solubility and tissue culture studies suggest a slightly decreased level of crosslinking[52,53] but there is no dramatic change in the lysyl oxidase activity[54] or the type of crosslink in these disorders[55]

In the more common debilitating connective tissue diseases a rapid proliferation of collagen often occurs resulting in the malfunction of certain tissues as with skin in scleroderma, the joint capsule in osteoarthrosis, the synovial membrane in rheumatoid arthritis, hypertrophic scar, cirrhosis and arteriosclerosis The increased accumulation of collagen may be due either to increased synthesis, or to a decrease in catabolism, the latter being possibly due to inhibition of the collagenases or to the type of crosslink being synthesised In scleroderma the newly synthesised collagen possess the labile crosslinks of young skin[56] and in rheumatoid synovium and granulomas[38] the stable keto crosslink is formed, results which may influence rate of catabolism and subsequent treatment of the disease

In conclusion it may be stated that at least some of the reduced components in borohydride reduced collagen exist in their nonreduced form as intermolecular crosslinks determining the physical characteristic of the fibre during the rapid growth and remodelling process Further, some correlation between the type of crosslink and the pathology of the tissue is beginning to emerge The next stage should be directed towards the elucidation of the nature of the stable nonreducible intermolecular crosslinks present in mature collagen in order to further elucidate the nature of collagen in health and disease

Infrared stars or infrareddened stars?

D. A. Allen & M. V. Penston

Royal Greenwich Observatory, Herstmonceux Castle, Hailsham, Sussex BN27 1RP, UK

Extreme interstellar reddening, accompanying visual absorption of order 100 magnitudes, is still a viable explanation for infrared objects like Becklin's star in spite of recent claims to the contrary It is unnecessary at this stage to invoke a new phase of protostellar evolution to account for them

SOURCES in regions of star formation which do not correspond to any optical stars are among the most interesting new types of object found by infrared astronomers The best known of these[1] is variously known as BN, Becklin's object and Becklin's star It has a colour temperature near 600 K Infrared sources which may be similar objects have subsequently been found in other star-formation regions, notably NGC 2264 (ref 2), Cas OB6(W3) (ref 3) and the R CrA association[4] The source in W3—called IRS 5—has a colour temperature as low as 200 K, but the other two are less extreme than Becklin's star and lie near the apexes of small conical nebulae

Becklin and Neugebauer proposed[1] that their source was a young object—perhaps a protostar—buried in a dust cocoon and that its infrared emission derived from re-radiation by the dust cloud This explanation was widely accepted until 1971 when Hyland and ourselves[5] proposed that the infrared source was the photosphere of a very luminous star reddened by the presence of extreme quantities of dust For a typical reddening law the visual absorption, A_V, must be about 70 mag

At the time there were several pieces of evidence to support that view The colours in the 1 6 to 3 5 μm region were those of a reddened hot black body rather than a cool black body and microwave observations of the Orion Nebula showed it to be sufficiently dense that A_V across it must be of order 200 mag for a normal dust to gas ratio Further, Becklin's star is immersed in an extended 20 μm source (KL, the Kleinmann–Low nebula) which is naturally accounted for as the thermal radiation of the absorbing dust This nebula is optically thick at 20 μm, also suggesting high visual extinction Because the 2 μm spectrum is featureless[5], Becklin's star must have a spectral type earlier than G and later than about B, Penston *et al* [5] favoured an F star because stars of that spectral type having the required luminosity (10^5 $L_\odot$) are known in other galaxies

In ref 5 it was predicted that the ubiquitous silicates, found in emission in a separate extended source near the Trapezium cluster[6], would produce an absorption feature in the 10 μm spectrum of Becklin's star The silicate absorption was indeed found by Gillett and Forrest[7] who also reported an absorption band at 3 2 μm due to water ice Both these features are about 1 mag deep Further support for the heavy reddening hypothesis was provided by infrared polarimetry At most infrared wavelengths, and in particular within the silicate absorption band, Becklin's star is the most strongly polarised source known A typical value for the linear polarisation is 10% (refs 8–10), scattering by dust particles is the mechanism usually invoked to explain such large polarisations

In spite of these accumulated supporting data, the heavy reddening hypothesis has been criticised recently, and even held to be no longer tenable Becklin, Neugebauer and Wynn-Williams found Becklin's star at 20 μm to be brighter by 1 5 mag than a hot reddened star fitted to the short wavelength data[11] They argued that dust accounted for the flux at 20 μm and therefore may contribute strongly at all other wavelengths They suggested that A_V is about 10 mag by comparison with the galactic centre source which they took to have an A_V of 25 mag on the basis of its 2 μm colours, and to have a silicate absorption twice as deep as that in Becklin's star

Criticism has also come from Rieke, Low and Kleinmann[12] who made high resolution maps of the region at various wavelengths in order to disentangle the contributions from BN and KL By combining their derived fluxes with data at longer wavelengths, Rieke *et al* deduced the luminosity of the KL nebula to be about 5×10^4 $L_\odot$ If the Kleinmann–Low nebula absorbs most of the energy of the underlying star it must essentially have the luminosity of that star The figure 5×10^4 $L_\odot$ is too low to be reconciled with the best available photometry of Becklin's star

This situation is worsened by the discovery[12] that Becklin's star is only one of several similar sources that cluster within the KL nebula Some of these sources were found by Wynn-Williams and Becklin[13] and given different designations In Table 1 we list all the infrared sources known in the Orion Nebula There are two distinct types most are compact objects less than 2 arc s diameter, but three are extended and can be attributed to thermal radiation from hot gas (free–free emission) or cool dust It is not clear from present data whether two of the 'compact' sources, IRc4 and IRc5, really are compact or are small condensations in the Kleinmann–Low nebula According to Rieke *et al*, IRc2, 3, 4 and 5 are redder than Becklin's star and probably have deeper silicate absorptions

It is important to clarify the essential issue underlying this controversy about the value of the absorption (which we will continue to measure by A_V while noting that it is in fact determined at 2 μm) If A_V lies in the range 65 to 70 mag, the unreddened source can be explained by a normal star in the temperature range 5,000 to 12,000 K Such stars are consistent with the 2 μm spectrum On the other hand if A_V is less than 45 mag the unreddened source has a colour temperature below 1,500 K and the radiation must originate principally from dust grains No consistent model exists with A_V between 45 and 65 mag In the second case Becklin's star may be an example of a new class of prestellar object On the evidence available so far, must such new objects be invoked or can an explanation in terms of normal stars be retained?

It seems most unlikely that A_V can be as low as the 10 mag suggested by Becklin *et al* [11], since there is no sign of anything like such strong silicate or ice absorption in stars, such as Cyg OB2 12 (ref 14) and MWC349 (ref 15), with $A_V \sim 10$ The comparison with the galactic centre is of dubious weight since the 2 μm galactic centre source (on which A_V is based) and

Table 1 Infrared sources in the Orion Nebula

Type of source	Designation		Probable A_V (mag)	Notes
	ref 12	ref 13		
Definitely compact (stars)	IRc1	BN	70	
	IRc2		100	included in IRS 3?
	IRc3	IRS 3	160	
		IRS 2	40	
		IRS 4	?	near NA
Compact or dust concentrations?	IRc4	core of KL	≤200	
	IRc5		?	seen only at 21 μm
	IRe2	KL	50–200	
Extended	IRe1		small	free-free component
		NA	small	Trapezium

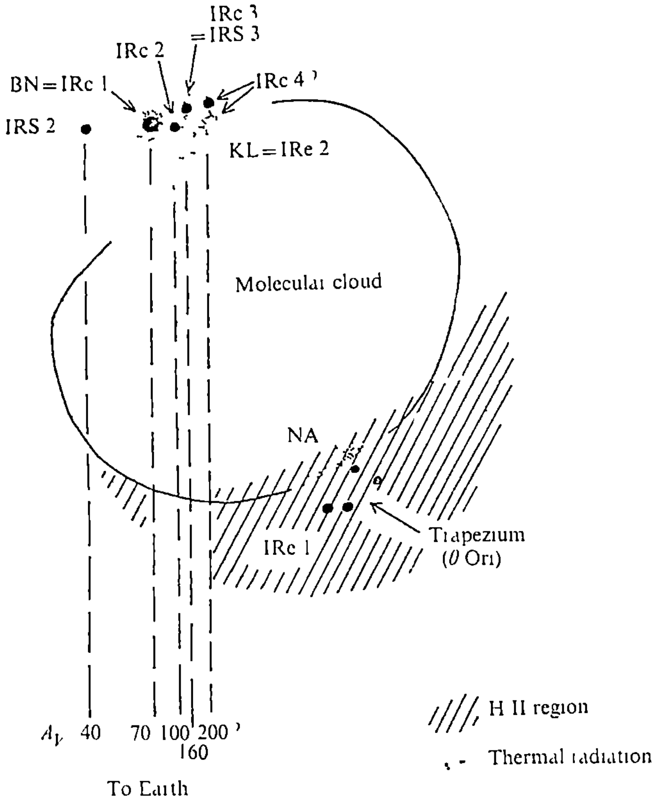

Fig. 1 Schematic diagram of M42 sliced through position angle 145°–325° The solid boundary to the neutral cloud is intended to represent not the limit of the material but a contour above which the density is very high IRc5 and IRS 4 are not plotted because of the uncertainty of their nature

the 10 µm source (with silicate absorption) have different structure[16] In general an extended source will tend to show smaller absorption at shorter wavelengths if the absorbing medium is clumpy Further, although the ratio of the equivalent widths of the silicate bands in the galactic centre and Becklin's star is about two, a more sophisticated analysis[17] including the effect of emission shows the column density of silicates to be more nearly the same

The choice between an A_V of 30 to 45, consistent with Rieke *et al*'s model of a cluster of protostars completely enveloped in the Kleinmann–Low nebula, and an A_V of about 70 is not so easily made We wish to point out that the latter is by no means untenable and that only slight modifications to the original version of ref 5 are necessitated by the large number of new data We must now explain (i) the 20 µm excess and (ii) the discrepancy in luminosity between the KL nebula and the cluster of stars

The 20 µm excess

There is no difficulty in finding a mechanism to produce the 20 µm excess Re-radiation by cool (~ 200 K) dust, or possibly free–free emission by circumstellar gas, can provide the necessary 20 µm flux without significantly affecting the near infrared colours An explanation based on dust at such a temperature would not require the source to be more extended than 1–2 arc s Dust re-radiation would also tally with the silicate emission implied in ref 17

On the other hand the dereddened 5–20 µm colour and the gradient of the 8–13 µm continuum fit a free–free slope Such a free–free component could not, however, originate in an ionised hydrogen shell without the simultaneous emission of a Brackett γ line, sufficiently intense to have been detected by Penston *et al*[5] Cool ionic free–free, as considered by Dyck and Milkey[18], is an outside possibility

The luminosity

Because insufficient luminosity is re-radiated by the KL nebula, it cannot completely surround the stars We therefore now envisage a cluster lying at the far side of the Orion Nebula just as the Trapezium cluster lies on the near edge (Fig 1) There would not necessarily be any manifestations at optical wavelengths of the presence of such luminous stars outside the nebula and essentially unobscured from some aspects In particular any Lyman continuum radiation is soaked up by the circumstellar gas so these stars would be incapable of ionising more distant nebulosity

It is relevant that very luminous F and G type stars are seen associated with star-formation regions in the Large Magellanic Cloud[19] Luminosities run up to $10^6\,L_\odot$ as in HD268757 which is associated with the nebula N83 Thus a star of $10^5\,L_\odot$ is by no means exceptional We are not privileged to examine the star-formation regions in our own galaxy face on, these extremely bright stars might well be hidden behind dust clouds

A more severe problem arises in the case of IRS 5 in W3 if this source too is to be explained as a highly reddened star To account for the depth of the silicate feature[17] we need only assume the ratio of silicate to total absorption to differ marginally from that of Becklin's star But the near infrared photometry implies a total luminosity of $\sim 3\times10^6\,L_\odot$ even if we choose what seems to be the more reliable distance of 2 kpc for Cas OB6 (ref 20) rather than the value of 3 kpc used to date in discussions of this infrared star Like Becklin's object, the reddened star must have a 20 µm excess A multiple system of very luminous stars could account for this object also, an alternative is a truly remarkable (and possibly unstable) single object of the type discussed by Hoyle, Solomon and Woolf[21] That W3 IRS 5 must also lie at the back of its absorbing cloud is implied by the 100 µm flux reported for this source[22] which at 2 kpc corresponds to a luminosity of $5\times10^5\,L_\odot$ Most or all of the flux can be accounted for by other sources in W3 (such as IRS 2 of ref 3), so IRS 5 may lie so far back of the absorbing cloud that there is essentially no re-radiation

The Kleinmann–Low nebula

Returning to discuss the details of the Orion Nebula sources, we note that in our model the Kleinmann–Low nebula is also seen through dust and could have an A_V as high as 200 mag Gillett and Forrest[6] suggested that the optical thickness of the silicate absorption in the KL nebula is much greater than in Becklin's star, implying a higher A_V The polarisation is also higher[10] Unfortunately, the interpretation of these data is complicated The two source picture (BN+KL) was extant when these

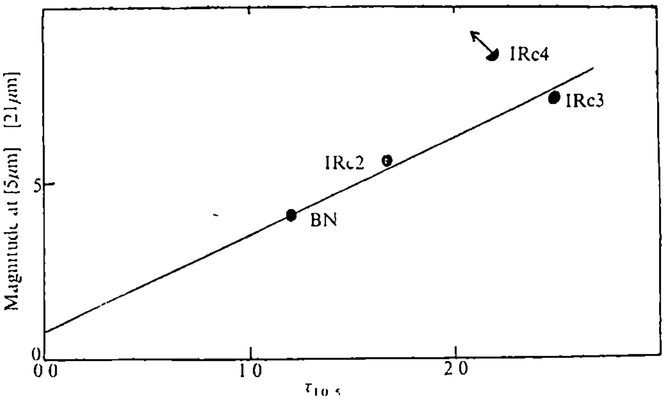

Fig 2 A plot of the 5 µm to 21 µm colour index of the compact infrared sources in M42 against the depth of the silicate feature below a reddened continuum fitted at 5 and 21 µm The data are from ref 12 This correlation can be explained if the sources have similar intrinsic 5–21 µm colour indices and are reddened in proportion to the silicate absorption

observations were made, but now we know of many sources Establishing how much each source contributes to each observation is impossible without a very accurate knowledge of the size, profile, separation and position of the beams at the time of observation The uncertainty has only minor effect on the results for Becklin's star itself, but could greatly distort the results for the extended source

Observational tests

It is not easy to distinguish between the 10,000 K, 70 mag model and the ~1,200 K, ~ 30 mag model One method would be to measure interferometrically the diameter of Becklin's star at 5 μm where the long wavelength component is negligible and scattering should not much increase the apparent size A baseline of 500 m would be needed

An alternative would be to deduce the relationship between A_V and the depth of the silicate or ice absorption For example more stars like Cyg OB2 12 and MWC349, and possibly the galactic centre, should be observed in this way The form of the interstellar absorption curve in the near infrared should follow from these observations as well as the depths of selective absorption features If infrared sources like those in NGC2264 and R CrA do fit into this scheme they may be most valuable as intermediate cases since the optical nebulae probably caused by reflection[4,23] indicate the presence of hidden stars The ratios of continuous to selective and of optical to infrared absorption are unlikely to be constant throughout the Galaxy, so this process is best done for the immediate vicinity of the Orion Nebula, where there may be no suitable sources From the data given in ref 12 we may, however, deduce a relationship between the reddening at 5 μm and the apparent depth of the silicate feature In Fig 2 we have plotted the 5 μm to 21 μm colour index in magnitudes against the optical depth at 10 5 μm in the silicate band The tight correlation exhibited by BN, IRc2 and IRc3 is further evidence for the presence of reddening The limit on IRc4 does not fit this correlation, but we have already noted (Table 1) that this source may be of a different nature It is interesting that IRc3 seems to possess double the absorption found in BN The intersection of the best fit line with the [5 μm]–[21 μm] axis gives the intrinsic colour of the sources, assuming them all to be similar, this is seen to be small For a typical theoretical reddening law $A_V \sim 50 E_{[5]-[21]}$, but this seems to be an overestimate since it suggests $A_V > 100$ mag for BN, and this figure could be further raised if there is any silicate absorption at 21 μm Improved data might lead to a more reliable diagram of this kind Essentially identical conclusions follow from interpreting Fig 1 of ref 24 in the same way

A final test would be to obtain a better 2 μm spectrum of Becklin's star to search for normal stellar features, for example Brackett γ With the improvement in signal/noise ratio likely to be brought about by the introduction of InSb detectors, this is an attractive proposition

Even if Rieke *et al*'s model for the Orion sources is correct, absorptions with $A_V \geqslant 30$ mag shroud any optical counterparts from our view Such dense clouds and high absorptions were unanticipated before the advent of infrared astronomy they are now a recognised part of the process of star formation

We thank Dave Aitken and Gareth Wynn-Williams for discussions

Catalytic head assembling protein in virus morphogenesis

Jonathan King & Sherwood Casjens

Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

About 250 molecules of a 'scaffolding protein', not found in mature phage, catalyse the assembly of about 420 coat protein subunits into a precursor shell containing both proteins in concert with DNA encapsulation, all the scaffolding molecules exit from the precursor shell to take part in further rounds of the same process

SINCE Fraenkel-Conrat and Williams demonstrated that tobacco mosaic virus could be reconstituted from its purified protein and nucleic acid components[1], it has been widely believed that virus parts specify their own correct assembly Caspar and Klug[2] provided a geometrical model for the self assembly of spherical virus capsids as the aggregation of similar subunits into quasi-equivalent positions on the surface of an icosahedral shell There is

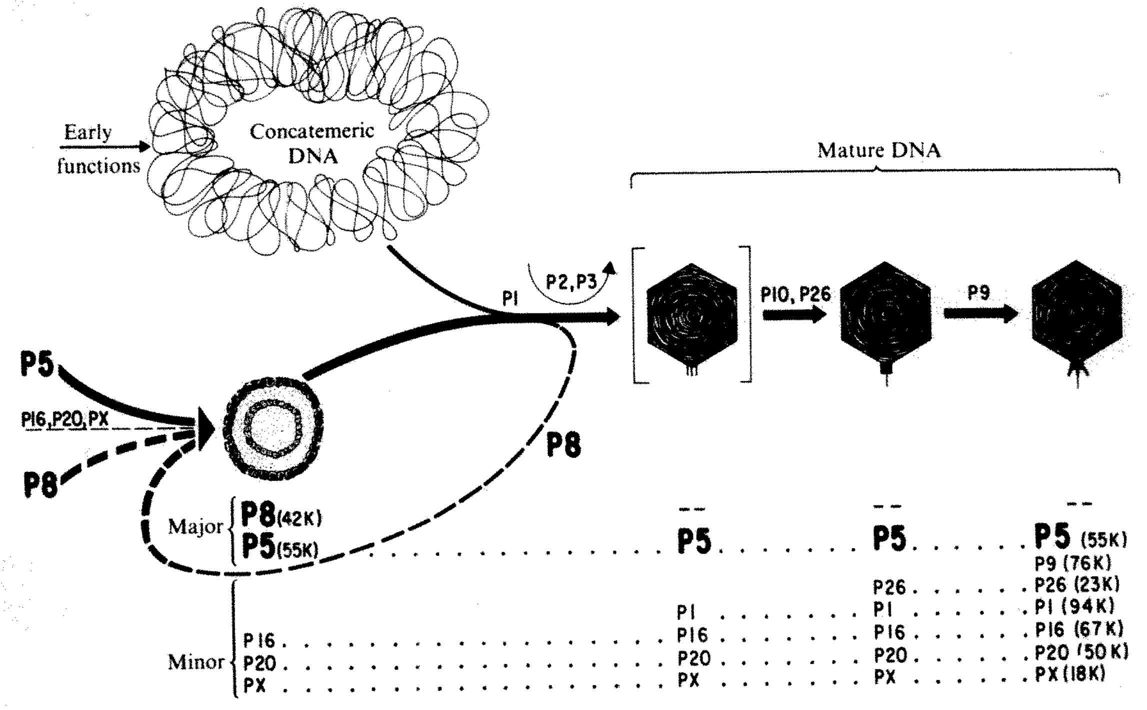

Fig. 1 Pathway of phage P22 head assembly and DNA encapsulation. This diagram summarises results from Botstein *et al*[17], King *et al.*[18] and this article. A prohead shell lacking DNA is the first identifiable structure in the pathway. It contains two major protein species, the products of gene *5* and gene *8*. (The products of genes *16* and *20*, though ordinarily incorporated into proheads, are not needed for morphogenesis.) With the incorporation of the product of gene *1*, and the function of the gene *2* and *3* products, the prohead encapsulates and cuts a headful of DNA from the concatemer DNA molecule, and concurrently P8 exits from the particle without proteolytic cleavage. The newly filled head is unstable (it loses the DNA) until acted upon by the gene *10* and *26* products, after which the complete head is converted to a phage particle by addition of the tail parts (gene *9* protein) as shown by Israel *et al.*[37]. P before a gene number refers to the polypeptide of that gene. The polypeptide chains found in each structure are listed below it, with their molecular weight shown in the last column. Brackets around the first filled head structure designate that it is unstable and loses DNA on isolation. The nature of the replicating DNA in P22-infected cells has been described by Botstein and Levine [22]; Tye *et al.*[16] have shown conclusively that P22 chromosome maturation proceeds by a "sequential headful cutting" mechanism[31].

now strong evidence that at least simple viruses conform to this pattern, and can self assemble from the separated components of the mature virus[3–5]. Recently, however, experiments with the more complex bacteriophages λ and T4 have shown that some proteins are required for assembly which are absent from the mature virus[6–9]. In addition proteolytic cleavage[5,8,10–12], and even covalent fusion[13] of structural proteins have been found to accompany the assembly of various viruses and bacteriophages. We describe here a protein that specifies the correct dimensions of a virus, catalytically, by temporarily complexing with the major coat protein to form a transient precursor shell of the virus. The dissociation of the protein from the precursor shell is associated with DNA condensation.

P22 is a temperate phage which infects the bacterium *Salmonella typhimurium*[14]. Its head is isometric, 600 Å in diameter, with a small spiked tail plate attached (Figs 1 and 2*b*), and contains double-stranded DNA of molecular weight 27×10^6 (ref. 15). The sequence present at one end of the chromosome is repeated at the other end to the extent of about 2%, and the genome is circularly permuted with respect to the chromosome so that the ends are not unique[15,16]. The DNA metabolism of infected cells, the genetic control of virus assembly, and the protein composition of virus particles have been described in detail by Botstein and coworkers[16–22]. For our purposes the important feature of the life cycle (Fig. 1) is the formation of a 240S head precursor structure, the prohead (Fig. 2*c* and *d*), which contains the major coat protein—the product of gene *5*—and a second major protein not found in mature phage, the product of gene *8*. (Proheads also contain three minor protein species, the products of genes *1*, *16* and *20*, but these are not required for prohead formation[17,18].)

The prohead is the precursor head structure in the cutting and packaging of a mature length chromosome from the overlength replicating DNA. This process requires the products of genes *1*, *2* and *3*; if any of these proteins are missing (due to mutation), proheads and uncut DNA accumulate[17]. The immediate product of DNA encapsulation is unstable until acted on by the products of genes *10* and *26*. If these proteins are missing the DNA comes back out, leaving empty heads, distinguishable from proheads by morphology and sedimentation. If cells are infected with *amber* mutants defective in gene *8*, most of the coat protein remains unassembled, or assembles into aberrant aggregates[18]. Since P8 is needed for the assembly of the coat protein into phage, but is not found in phage, we termed it a 'scaffolding protein'[18]. The P22 prohead is similar in this respect to tau particles of phage T4 described by Kellenberger *et al.*[23] and Simon[24]; Showe and Black[9] and Laemmli and Favre[25] have shown that such particles contain proteins needed for morphogenesis but absent from the mature phage.

We show here that the isometric capsid of phage P22 does not self assemble. Roughly 200–300 molecules of the scaffolding protein catalyse the accurate polymerisation of the coat protein into a precursor shell containing both proteins. Upon DNA encapsulation, all the scaffolding protein molecules depart from the precursor shell. These then proceed to catalyse the polymerisation of newly synthesised coat protein molecules into another precursor shell.

Protein composition of proheads

Proheads are the earliest shell structures detectable in the head assembly pathway[18]. We isolated proheads in high concentration from infected cells, separated their proteins

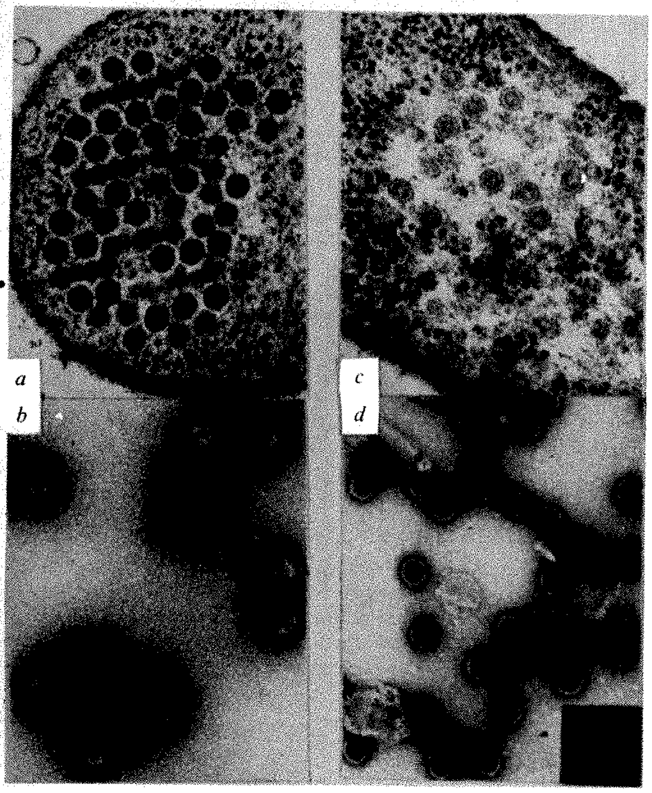

Fig. 2 Morphology of phage head structures. The upper panels are electron micrographs of ultrathin sections of P22 infected Su$^-$ DB21 (ref. 19) cells, prepared by the method of Simon[24]. Each lower panel is an electron micrograph of particles (negatively stained) isolated from cells infected with the same phage as the panel above it. *a* and *b*, Normal phage particles; *c* and *d*, proheads from cells infected with phage carrying an amber mutation in gene *2*. These structures contain both the coat protein and the scaffolding protein. The phage also carried the clear mutation c_1[7] to prevent lysogeny and a lysis defective mutation in gene *13* (*am*H101)[17]. A more detailed account of the *in vivo* morphology of the various head-related structures formed during P22 infection will be presented later (Lenk, Casjens, Weeks and King, in preparation). The magnification of all panels is ×60,000, and the magnification of the insert in panel (*d*) is ×140,000.

by electrophoresis through SDS acrylamide gels, and determined mass ratios by staining with Coomassie brilliant blue and fast green. We first used cells infected with *amber* mutants defective in genes *1*, *2* or *3*, since proheads are the only particulate phage structures (240S) formed in them. Proheads from mutant-infected cells are qualitatively indistinguishable from the precursor proheads isolated from wild type-infected cells[17,18]. Proheads were isolated from crude lysates by centrifugation through a sucrose-caesium chloride step gradient, and then further purified by centrifugation through a sucrose gradient, as described in the legend to Fig. 3. An electron micrograph of the resulting preparation is shown in Fig. 2*d*. Figure 3*h* (bottom right) shows the proteins of a *2*$^-$ prohead (proheads from cells infected with an *amber* mutant in gene *2*) separated on an SDS gel and stained with Coomassie brilliant blue, with a densitometer tracing above. P8 is a major component. Proheads isolated from *1*$^-$, *2*$^-$, and *3*$^-$-infected cells were very similar in protein composition (except that the *1*$^-$ proheads lacked P1, as expected[18]).

The results of many gel analyses are summarised in Table 1. Taking 420 as the number of coat protein subunits[17], and assuming equivalent binding of the stain to the two species of protein, we calculated that the proheads accumulating in *1*$^-$, *2*$^-$, and *3*$^-$-infected cells contain about 260 molecules of P8. In the lysates from which these particles were isolated, more than 90% of P5 and P8 molecules were in proheads.

To determine the ratio of scaffolding protein to coat protein in proheads from productive infected cells, we infected a culture with P22 and isolated proheads from samples lysed 22, 51, 90, and 109 min later. Figure 3*a–d* shows that P8 is a major component of these precursor structures. However, wild-type infected cells also contain empty heads, which lack P8 (ref. 18). These sediment at 170S and contaminate the 240S prohead fractions. From electron micrographs of negatively stained samples of the isolated wild type proheads, we estimated the contamination to be about 30%. Table 2 gives the number of P8 molecules in proheads isolated from productively infected cells, corrected for contamination by empty heads. The

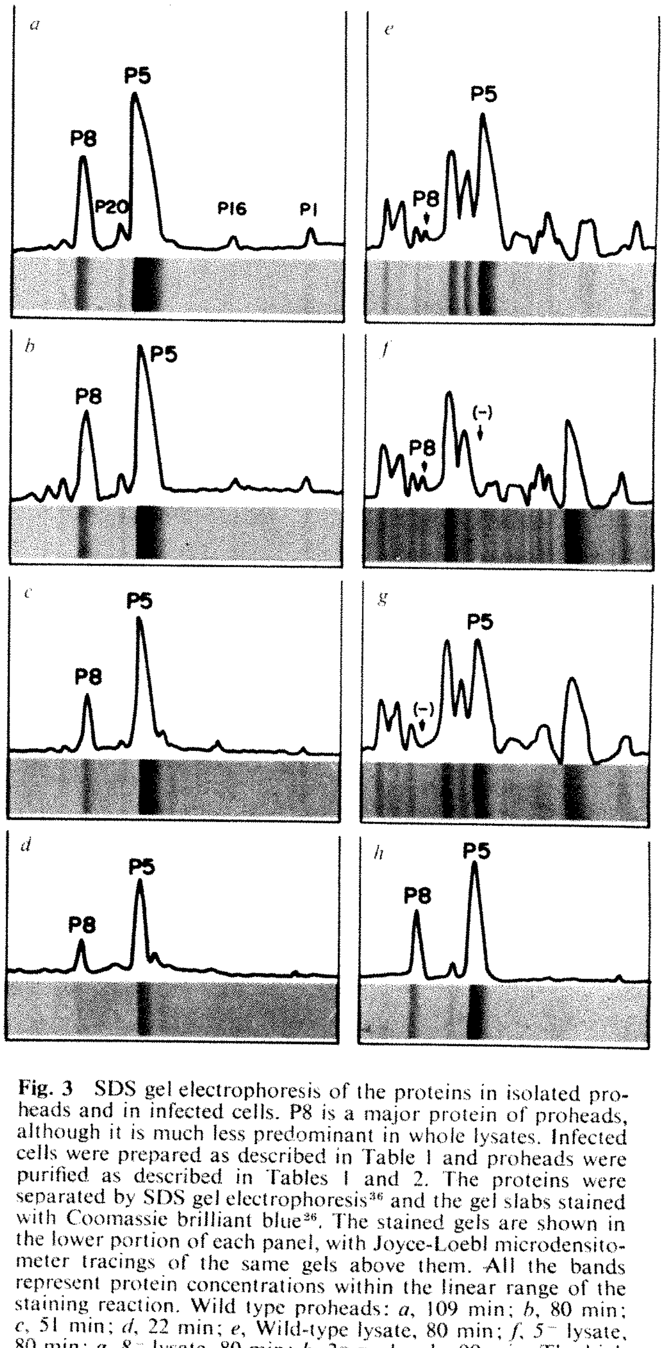

Fig. 3 SDS gel electrophoresis of the proteins in isolated proheads and in infected cells. P8 is a major protein of proheads, although it is much less predominant in whole lysates. Infected cells were prepared as described in Table 1 and proheads were purified as described in Tables 1 and 2. The proteins were separated by SDS gel electrophoresis[36] and the gel slabs stained with Coomassie brilliant blue[26]. The stained gels are shown in the lower portion of each panel, with Joyce-Loebl microdensitometer tracings of the same gels above them. All the bands represent protein concentrations within the linear range of the staining reaction. Wild type proheads: *a*, 109 min; *b*, 80 min; *c*, 51 min; *d*, 22 min; *e*, Wild-type lysate, 80 min; *f*, *5*$^-$ lysate, 80 min; *g*, *8*$^-$ lysate, 80 min; *h*, *2*$^-$ proheads, 90 min. The high molecular weight regions of the gel are to the right. The band which is present in increased amounts in the *5*$^-$ and *8*$^-$ lysates is P9, the tail protein[17,37]. Gene *9* is subject to a control system different from the other late proteins (Lew and Botstein, unpublished experiments): it is overproduced in cells infected with mutants blocked in DNA encapsulation. This phenomenon is independent of the overproduction of P8 described later in the text.

Table 1 Protein composition of proheads

	Stain	Molecules of P8 per 420 P5 molecules*
1^- Proheads	Coomassie blue	259±16
	Fast green	245± 8
2^- Proheads	Coomassie blue	266±16
	Fast green	not done
3^- Proheads	Coomassie blue	270± 7
	Fast green	251±10
++ Proheads†	Coomassie blue	239±25
	Fast green	252±20

Proheads were prepared as follows cultures of the su$^-$ bacteria DB 21 (ref 19) were grown to 2×10^8 cells per ml in broth[20] at 37° C, infected with P22 carrying the clear marker c_1[7], a lysis-defective mutation in gene *13* (*am*H101) and an *amber* mutation in gene *1* (*am*N10), gene *2* (*am*H200), or gene *3* (*am*N6)[17], at a multiplicity of five After 90 min of aeration, cells were pelleted, resuspended in about 0 002 volumes of 0 02 M Tris-HCl, 10^{-3} M $MgCl_2$, *p*H 7 5, *containing chloroform (to induce lysis)* and pancreatic DNase (to reduce viscosity) The cell debris was removed by low speed centrifugation, and the clear, opalescent supernatant was layered on a 15–30% sucrose gradient and centrifuged at 20,000 r p m for 2 h in an SW 27 1 rotor Opalescent prohead bands were removed by piercing the side of the tube with a syringe The proteins of the purified proheads were separated by SDS polyacrylamide slab gel electrophoresis[35 36] The resulting gels were stained with Coomassie brilliant blue[26] or fast green[27], and tracings of the coloured bands were made with a Joyce-Loebl microdensitometer The ratio of copies of P8 to P5 was calculated from the areas under the peaks after correcting for the molecular weight differences All measurements were made *within the range in which stain density was proportional* to the amount of sample applied to the gel

* Average of a minimum of four polyacrylamide gel experiments The errors are the calculated standard deviations

† Corrected for the fraction (15–30% among 250–750 particles counted on electron micrographs) of contaminating empty heads (which contain no P8) The mutant prohead preparations contain no empty heads

ratio of scaffolding protein to coat protein in these precursor *proheads did not change significantly throughout* infection, and was similar to the P8/P5 ratio in proheads isolated from *1*$^-$, *2*$^-$, *and 3*$^-$-infected cells The slightly higher P8/P5 ratio of the wild-type proheads may be due to overestimation of the contamination by empty heads

Since the amino acid composition of these proteins is unknown, we do not know if P8 and P5 bind the same amount of dye per mg of protein Published results indicate small differences in binding for different proteins[26 27] We therefore conclude that the prohead intermediates in phage P22 assembly contain 200–300 P8 scaffolding protein molecules for every 420 P5 coat protein molecules

The ratio of P8 to P5 in proheads is quite different from the ratio of the two proteins in the total culture, as can be seen by comparing the lysate gel patterns of Fig 3*e* with the prohead patterns P22-infected cells accumulate very little P8 with respect to P5 The *5*$^-$ and *8*$^-$ mutant lysates (Fig 3*f*,*g*) provide positive identification of the two proteins

Figure 4 shows the rates of synthesis for the two proteins during infection, determined from the extent of incorporation of ^{14}C-labelled amino acids during short pulses At late times 15–20 copies of P5 coat protein were synthesised for every copy of P8 synthesised

Botstein *et al*[17] showed that there was no detectable cleavage of late proteins in P22-infected cells We have *performed further* pulse-chase experiments to look for proteolytic cleavage of P8, using shorter pulse times—75 s at 30° C Samples withdrawn from the culture at various times after chase were lysed immediately with chloroform, mixed with sodium dodecyl sulphate (SDS) sample buffer, and frozen before electrophoresis through an SDS gel slab Recovery of radioactive P8 (weight of peak from densitometer tracing of autoradiogram) after the chase was as follows *15* s, *56* mg, 2 min, 67 mg, 5 min, 73 mg, 9 min, 82 mg, 13 min, 73 mg, 18 min, 79 mg We conclude that P8 is not cleaved to lower molecular weight during the phage life cycle Since P8 is not in phage, and *is not degraded, it must be removed from proheads intact*

P8 recycled during morphogenesis

If 200–300 molecules of P8 are required to make a prohead, and therefore a phage, and if each molecule of P8 were to take part in the formation of only one prohead, then Figs 3 and 4 indicate that too few molecules are made to account for the yield of viable phage particles Pulse-chase experiments[18] suggested that P8 is reused during infection, that is, after release from a prohead taking part in DNA encapsulation, the P8 molecules take part in further rounds of prohead assembly If this is true, then P5 coat protein molecules should chase from proheads into phage, but the P8 scaffolding protein should remain with the prohead fraction, complexed with newly synthesised coat protein molecules

To test this prediction, infected cells were exposed to radioactive amino acids continuously from 12 min after *infection (which is before the onset of late protein syn*thesis) to 28 min after infection, so that all the molecules of P8 and P5 synthesised up to that time would be radioactive At 28 min excess unlabelled amino acids were added to stop the uptake of labelled amino acids At various times measured from the start of the chase (1, 2, 4, 7, 11, 16 and 22 min) samples of the culture were shaken with chloroform to lyse infected cells, and aliquots of the lysates were centrifuged through sucrose gradients, first to separate phage particles (500S), and then at higher speed to separate proheads and empty heads (240S and 170S) The radioactivity in the prohead and empty head peaks decreased with time after the chase, and the radioactivity in the phage peak increased, as expected[18] (data not shown) To follow the fate of P5 and P8 molecules individually, we dissociated the prohead, empty head, and phage-containing sucrose gradient fractions in hot SDS, and electrophoresed the samples through an SDS gel slab The resulting autoradiograms displayed the expected band patterns[18] proheads contained P5 and P8 as the dominant bands, plus much smaller amounts of radioactive P1, P16 and P20 In comparison the phage lacked the P8 band but displayed tail protein (P9) and P26 and PX The empty heads were similar to the proheads except they also lacked P8 Figure 5 shows that labelled coat protein chased from proheads and empty heads into phage, while labelled scaffolding protein remained associated with the prohead fraction Since the ratio of P5 and P8 in proheads does not change during infection (Table 2) the radioactive P8 must have associated with nonradioactive coat protein

Table 2 Number of molecules of P8 in head structures isolated at various times after infection

	Time after infection			
	22 min	51 min	80 min	109 min
Proheads	295±30	290±25	315±30	300±25
Empty heads	< 10	< 10	< 10	< 10
Phage	< 10	< 5	< 2	< 2

Errors represent the limits of at least two determinations Particles were purified and values for P8 determined as described in the legend of Table 1

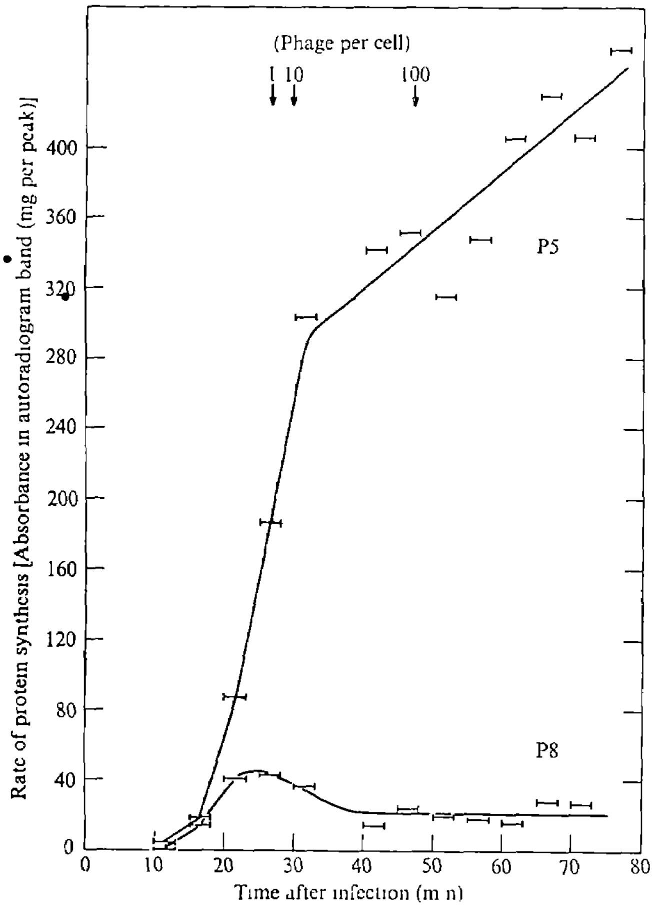

Fig 4 Rate of P8 and P5 synthesis in phage-infected cells *S typhimurium* D21 was grown in M9 medium[17] at 37° C to 2×10^8 cells per ml and infected with five $c_1 13^-$ phage per cell At the times shown, samples of the culture were incubated with ^{14}C-labelled amino acid mixture to give a final concentration of 0 2 μCi ml^{-1} Three minutes later incorporation was stopped by addition of excess casamino acids, and after a further 1 5 min incubation, the cells were chilled in ice and then centrifuged at 4,000 r p m for 10 min The resulting pellet was resuspended in 1/4 the original volume and lysed by shaking vigorously with chloroform Samples were heated in SDS sample buffer and the proteins separated by electrophoresis through a 12% SDS polyacrylamide slab gel[35 36] Densitometer tracings of appropriately exposed autoradiograms were prepared[38] and the peaks representing the bands of radioactive P8 and P5 cut out and weighed Experiments performed at 30° C gave similar results, as did experiments in which cells were lysed immediately after the chase of the radioactive amino acids

synthesised after the chase The simplest interpretation of these results is that on encapsulation of DNA by the prohead, all the P8 molecules dissociate from the complex, and rapidly reassociate with more coat protein to form further proheads (These proheads would also be expected to contain newly synthesised unlabelled P8, which would not have been detected in the experiment)

Suppose a prohead is formed of both previously synthesised and newly synthesised scaffolding protein, but only newly synthesised coat protein, then after short pulses of label, the ratio of labelled P8 to labelled P5 in proheads should decrease for pulses given later and later during infection, since the pool of unlabelled recycling P8 will increase with respect to the pulse labelled P8 To test this prediction infected cells were exposed to 3-min pulses of radioactive amino acids at various times after infection Two and one half minutes after the chase of radioactivity, samples were lysed and centrifuged through sucrose gradients to separate proheads This was sufficient time for much of the pulse labelled P5 and P8 to form proheads, but not long enough for substantial label to appear in phage[18] The prohead proteins were separated by SDS gel electrophoresis and autoradiograms prepared and tracings made from them The molar ratio of P8 to P5 radioactivity in pulse labelled proheads was as follows 33 min, 21%, 44 min, 9 9%, 51 min, 7 8%, 60 min, 5 2% The ratio of labelled P8 to P5 in proheads clearly decreased as the infection progressed Since the total protein composition of these particles was not different (Table 2), we ascribe the decrease to the presence of unlabelled recycling P8 synthesised before the pulse period

How many rounds of prohead assembly does each P8 molecule participate in, on the average? To answer this question we measured the total amount of P5 and P8 in the whole lysate by Coomassie brilliant blue staining of SDS gels, and also measured the P5 and P8 in the proheads, empty heads, and phage fractions isolated from the lysate Given that it takes about 250 molecules of P8 for the incorporation of 420 molecules of P5 into phage, we calculated how many times the P8 in the culture at the time of lysis would have had to function, to account for the amount of coat protein assembled into particles (phage + empty heads + proheads) present in the culture at the time As Fig 6 shows, this number increases during infection and is about 5 at the time the cells would have lysed (45 min) if the phage were not carrying a lysis delay mutation

Since this is a somewhat unusual catalytic protein, in which the formation of the product requires the concerted reaction of more than two hundred catalyst molecules, we have not expressed the data in Fig 6 as an enzymatic turnover number The value corresponding to that is about 0 2 phage per minute per 250 P8 molecules at 37° C

Prohead assembly

The experiments described here show that about 250 molecules of the 42,000 molecular weight gene *8* scaffolding protein catalyse the assembly of about 420 molecules of the 55,000 molecular weight gene *5* coat protein into a precursor prohead shell containing both proteins The scaffolding protein then exits from the prohead in concert with the condensation of the phage DNA, yielding a packaged chromosome and free scaffolding protein, which then repeats the cycle Proheads could be described as giant enzyme–substrate complexes, no scaffolding protein is detectable in virus particles containing DNA, the product of the reaction

That proper shell formation depends on the participation of the scaffolding protein is shown most clearly by the analysis of gene *8* mutants cells infected with amber mutants defective in gene *8* synthesise normal amounts of coat protein (Fig 3*f*) but this protein does not assemble efficiently into closed shells[17 18] Instead, aberrant aggregates are formed, among these are shells with smaller diameter than phage, and larger 'spiral' structures This latter class looks like a shell which has failed to join its growing edges, and then kept adding subunits at the exposed edge Nested shells have also been seen We have performed pulse-chase experiments with 8^--infected cells which show that P5 assembles into aberrant structure less than 1/5 as efficiently as the P5 in wild-type infected cells assembles into proheads These experiments suggest that the scaffolding protein increases both the rate and accuracy of shell formation

What is the structure of the prohead complex? The electron microscopic appearance of proheads in both negatively stained specimens and ultrathin sections of infected cells shows organised internal structure (Fig 2*c*, *d*) The images suggest either a double shell structure, or a ball within a shell Since the outer shell has dimensions similar to the mature phage, and also represents more mass than the inner material, we presume that the outer shell is made of coat protein, and the inner material represents the scaffolding protein The two proteins could be intimately associated as a single thick shell, and the appearance in thin sections could be due to an artefact of fixation or staining Since the capsid of the mature phage is most likely a lattice with icosahedral symmetry[2], it seems probable that the prohead also represents an icosahedral type surface lattice Much less clear is the symmetry expected of the scaffolding protein organisation

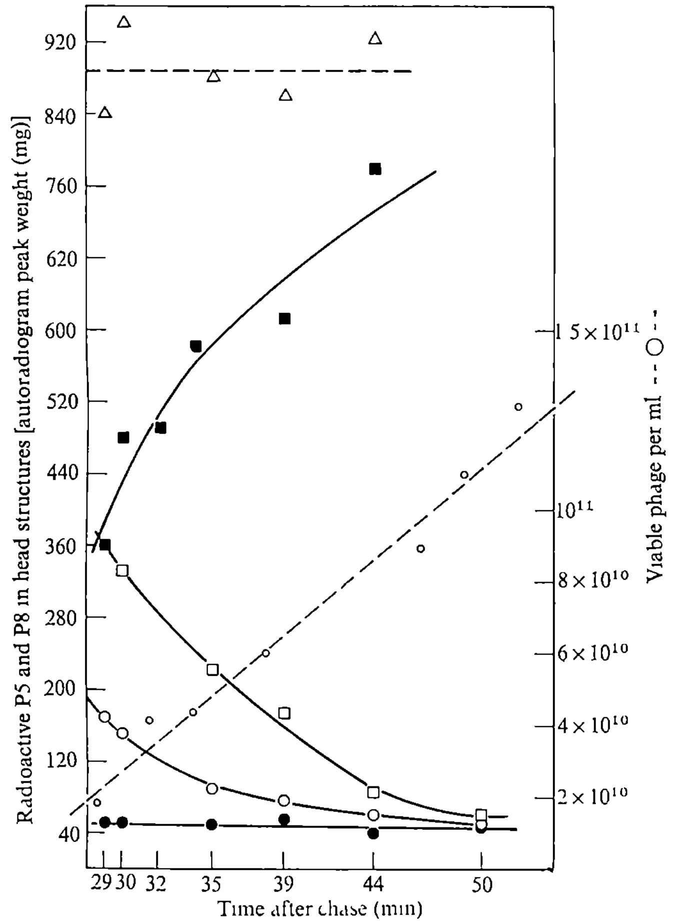

Fig 5 Continued association of labelled scaffolding protein with proheads during phage growth This figure summarises the fate of labelled coat and scaffolding protein after a chase of radioactivity which had been present continuously from 12 to 28 min after infection The amount of labelled P5 in the phage fraction (■) increases after the chase while the amount of labelled P5 in the prohead (○) and empty head fractions (□) decreases with time after the chase However, all of the labelled P8 associated with proheads (●) at the time of the chase remains associated with proheads even though these structures are serving as intermediates in assembly and the P5 associated with them is converted to phage That viable phage are continuously forming is shown by the dashed line The open triangles show the sum of the labelled P5 from the various fractions Though not shown in the figure, the minor proteins present in proheads P1, P16 and P20 also chased from the prohead fraction into the phage fraction during the chase The experiment was performed as follows D21 was grown in M9 medium[17] at 30° C to 2×10^8 cells per ml and infected with 10 c_1*13*$^-$ phage per cell At 12, 16, 20 and 24 min after infection, 2 5 µCi of ^{14}C-labelled amino acid mixture was added per ml of culture (giving a final concentration of 10 µCi ml^{-1}) At 28 min excess casamino acids were added and at 1, 2, 4, 7, 11, 16 and 22 min thereafter, samples were lysed by shaking vigorously with chloroform Incorporation of radioactivity into trichloroacetic acid insoluble material was linear during the labelling period For separation of phage, 0 25 ml aliquots were centrifuged through 5–20% sucrose gradients in 0 01 M Tris buffer, with a shelf of 0 3 ml of CsCl, ρ - 1 6 g cm^{-3} Centrifugation was for 20 min at 20,000 r p m , 20° C For separation of proheads and empty heads (*a* and *c*) 0 1 ml aliquots were centrifuged for 30 min at 30,000 r p m , 20° C Radioactivity was determined by mixing aliquots of the gradient fractions with Triton X-100/toluene based scintillation fluid and counting in a scintillation counter Particles from the sucrose gradient separations were dissociated in SDS sample buffer and electrophoresed through a 10% SDS polyacrylamide slab gel and the radioactive bands determined by autoradiography Densitometer tracings of the autoradiograms were made and the peaks cut out and weighed

How does the scaffolding protein control the assembly of the coat protein? The scaffolding protein itself might assemble into a large complex which serves as a template or 'assembly core' for coat protein polymerisation, as suggested[9,23] for phage T4 If that were the case we would expect to find such complexes in cells infected with coat protein amber mutants We find, however, that all the scaffolding protein in *5*$^-$ lysates sediments as free subunits (<4S) We have also been unable to see organised structures in thin sections of *5*$^-$-infected cells

These observations suggest that the scaffolding protein complexes not with itself initially, but with coat protein, and that a coat protein/scaffolding protein multimer is the functional unit in shell formation Presumably in the absence of the scaffolding protein, the bond angles between coat protein molecules are not specified rigidly enough to ensure that over a 1,900 Å circumference the edges will join properly Multimers of coat protein and scaffolding protein would be expected to have much larger reactive surfaces and thus be able to specify bond angles more accurately

Figure 4 shows that P8 is synthesised at a low level in wild-type infected cells We have also measured the synthesis of late proteins in cells infected with amber mutants in each of the P22 late genes The pattern of P8 and P5 synthesis is the same as wild type in cells infected with mutants which are capable of DNA packaging (*16*$^-$, *20*$^-$, *10*$^-$, *26*$^-$ and *9*$^-$) But, cells infected with mutants defective in genes, *1*, *2*, or *3* overproduce P8 4–8-fold In these cells P8 is trapped in the prohead complexes which accumulate and is not recycled The overproduction is not due simply to the large pool of unpackaged DNA that accumulates, since *5*$^-$-infected cells do not overproduce P8 Various experiments on the rate of P8 synthesis in mutant infected cells (unpublished experiments) indicate that the level of P8 synthesis is a function of the concentration of unassembled P8 Its synthesis is thus self-regulated, similar to the *Salmonella* histidine repressor[28], threonine deaminase[29] and T4 DNA polymerase[30] In the case of phage head assembly, this provides a feedback loop between DNA packaging and protein synthesis, if encapsulation is proceeding efficiently, P8 is released to form further proheads, and depresses its own further synthesis

Since P8 is a major component of proheads, its catalytic function saves the cell considerable protein synthetic capacity, the economy is even greater when the synthesis is regulated so that the protein is produced at a rate just sufficient for optimal assembly

P8 and DNA condensation

Although we have focused on its scaffolding function, the DNA condensation function of P8 might be of equal biological importance Since all phage head structures containing DNA lack P8, the 200–250 molecules of P8 must exit from the prohead before or during DNA encapsulation This unusual exchange reaction requires the products of genes *1*, *2*, and *3*, since if any one of them is missing, proheads and unpackaged DNA accumulate[17] P2 and P3 are not associated with proheads or phage, we suspect that they interact with precursor DNA, perhaps forming a binding site for proheads The actual condensation of the DNA within the head might be directly coupled with the exit of P8 According to Laemmli's model for DNA packaging[25], for example, the exit of P8 might expose charged sites within the head which serve to collapse the DNA The scaffolding protein might exit by

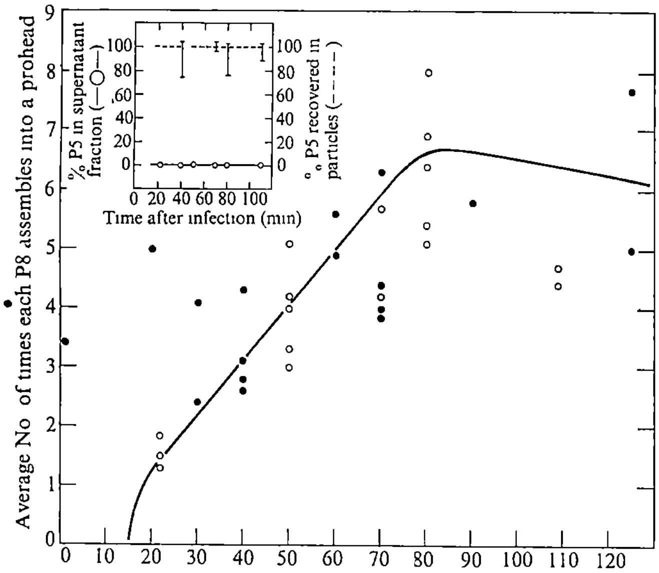

Fig 6 Recycling of scaffolding protein molecules The graph shows the average number of rounds of prohead assembly that each scaffolding molecule has taken part in during phage growth The calculation was as follows

$$\text{number of times P8 reused} = \frac{(\text{P8/P5})_{\text{prohead}}}{(\text{P8/P5 F})_{\text{cells}}}$$

where F is the fraction of the total P5 molecules in the cell which is in phage or phage precursor structures F was found to be very near 1 0 (see below) The open and closed circles represent two independent experiments *S typhimurium* DB21 was grown in broth to 2×10^8 cells per ml and infected with P22 $c_1 13^-$ at a multiplicity of 10 At the times indicated samples of the infected cells were pelleted, resuspended in 0 1 volume of electrophoresis buffer, heated to 100° C for 2 min, and the proteins were separated by SDS slab gel electrophoresis (see Fig 3) The protein bands were quantitated by tracing with a Joyce-Loebl microdensitometer, and the areas under the P8 and P5 peaks measured At various times after the infection described above, samples were also taken for analysis of the phage-specific structures present The infected cells were concentrated by centrifugation, lysed with CHCl$_3$, layered on the top of a sucrose gradient with a high density (1 6 g cm^{-3}) CsCl cushion, and centrifuged for 45 min at 45,000 r p m in a Beckman SW 50 1 rotor The fraction containing all the particles (phage, proheads and empty heads), that is, the top of the CsCl cushion, and the supernantant (top 1 5 ml) fraction were removed with a syringe, and the proteins separated and quantitated as above The insert in the figure above shows the results of such an analysis normalised to the total amount of P5 present

rearrangement of the coat protein shell over its entire surface, or through a single channel If the exit of P8 molecules is directly coupled to the entry of DNA, then the scaffolding protein catalyses not only shell formation, but also DNA condensation, since each molecule takes part in as many cycles of DNA packaging as it does of prohead formation

Since the P22 chromosome is packaged by a 'headful cutting' mechanism[16,17,31], the length of the chromosome must be determined by the size of the head Thus the scaffolding protein, in specifying accurately the dimensions of the prohead shell, is specifying the length of the virus chromosome

Proheads are similar in morphology to the T4 tau particles described by Kellenberger *et al*[23], Simon[24] and Laemmli[32] showed that these are precursors to phage, and Showe and Black[9] demonstrated that the inner material is probably an assembly core composed of the product of T4 gene *22* product and internal proteins The *22* product and internal protein III are cleaved down to fragments during DNA packaging[25] Thus, the P22 scaffolding protein and T4 assembly core are formally equivalent, in the former case the assembly core is removed by proteolytic cleavage during DNA packaging and in the latter case the protein is removed intact and then recycles Bacteriophages T7 and T3 may be assembled similarly to P22 since during infection a top component occurs which contains a protein absent from phage[33,34] This protein is not cleaved during assembly, and is specified by a gene which maps adjacent to the coat protein, just as in P22

Catalysis of morphogenesis

The first case in which a protein was shown to catalyse a step in morphogenesis was the attachment of T4 tail fibres to particles by gene *63* product (Wood and Heninger[6]) The gene *63* product is typical of an enzyme in that a stable complex with the two substrates could not be isolated We think the scaffolding protein represents a new kind of catalytic function (*a*) hundreds of protein molecules are necessary for the formation of one product of the reaction, (*b*) the catalyst molecules become a stable component of the immediate product of the reaction—in essence the scaffolding protein specifies the correct dimensions of the coat protein shell by temporarily becoming part of the shell, (*c*) the dissociation of the complex is a very complicated reaction requiring at least three other proteins, plus the encapsulation of a viral chromosome

Perhaps most important, these results show clearly that proteins critical for assembly may not be found as part of the mature structure[6–8,25] For example, the proteins which condense DNA into chromosomes in higher organisms may not be found in the mature chromosome We would also like to emphasise that although a major component of a viral precursor, the P22 scaffolding protein — because of its ability to recycle — is only a minor component of phage-infected cells We suspect that many structure formation processes will turn out to proceed by a similar combination of catalytic with self-assembly mechanisms

We thank Elaine Lenk for technical assistance and David Botstein and Carol Waddell for contributions in the early phase of the experiments We also thank Roni McCall and Max McDowell for help with the manuscript This research was supported by a grant to J K from the National Institutes of Health, Institute of General Medical Sciences, and by a Helen Hay Whitney Fellowship to S C

Operator and promoter are separate in the tryptophan operon in *Salmonella typhimurium*

Hiroyuki Aono, Frank Angelosanto & Elias Balbinder

Department of Biology, Syracuse University, Syracuse, New York 13210

Studies of the trp *mRNA made by* Salmonella typhimurium *strains carrying* trpOA *and* trpOAB *multisite mutations have shown that these are deletions They do not extend into the* trp *promoter* (trpP1) *as shown by their ability to recombine with* trpP4 *mutation Thus the* trp *operator* (trpO) *and the* trp *promoter are seperable and arranged in the order* P1-O-A

In a preliminary report[1] we presented evidence that in the *trp* operon of *Salmonella typhimurium* the promoter (*trpP1*) and operator (*trpO*) were separable and arranged in the order *P1-O* in relation to the first structural gene *trpA* (Fig 1) Part of this evidence was the observation that we were unable to find *supX-trpO* deletions but easily obtained multisite mutations with the characteristics of deletions extending from *trpA* to *trpO* and leaving *trpP1* intact We did not, however, exclude the possibilities that these multisite mutations were (*a*) insertions of extraneous genetic material[2,3] containing a functional promoter, or (*b*) deletions extending beyond *trpP1* and joining the remainder of the *trp* operon to an outside promoter We report here that our multisite mutations are indeed *trpA-trpO* deletions which do not extend fully into *trpP1*, thus strengthening our earlier conclusions about the order and separability of *trpP1* and *trpO*

The isolation of our multisite mutations was based on the observation that strains carrying strong polar mutations in *trpA* or in *trpB*-region I (Fig 1) grow very slowly on anthranilic acid supplement since they have very low levels of PRPP-phosphoribosyl transferase (PRT (EC 2 4 2 18) activity[4] Secondary mutants of such strains selected for improved utilisation of anthranilic acid, a substrate of PRT, cary deletions of various portions of the *trpA* gene and, depending on the mutants, *trpB*-region I (refs 4,5) Representatives of this class are *trpAB688* and *trpAB674* in Fig 1 By selecting simultaneously for normal growth on anthranilic acid supplement and resistance to 5-methyltrptophan (5MT), an analogue of tryptophan able to act as a corepressor[6], we obtained exclusively multisite mutations extending from *trpA* to *trpO* (ref 1) These are represented by *trpOA526, trpOAB673* and *trpOAB1349* in Fig 1 Since these presumptive deletions correct for a polar effect by increasing the level of activity of a growth limiting enzyme (PRT), they should end 'in phase' By transducing the mutant *cysB403* and the double mutant *cysB403* Δ*trpPOABEDC167* with lysates grown on each multisite mutant and plating on tryptophan supplemented minimal medium, we determined that all multisite mutations cotransduced with *cysB* at the same frequency as the wild type *trp* operon and were not translocations of the distal segment of the operon to the vicinity of some other promoter on the *S typhimurium* chromosome

We have been able to look at the *trp* transcripts of our *S typhimurium* mutants by taking advantage of the observation of Denney and Yanofsky[7] that *S typhimurium*

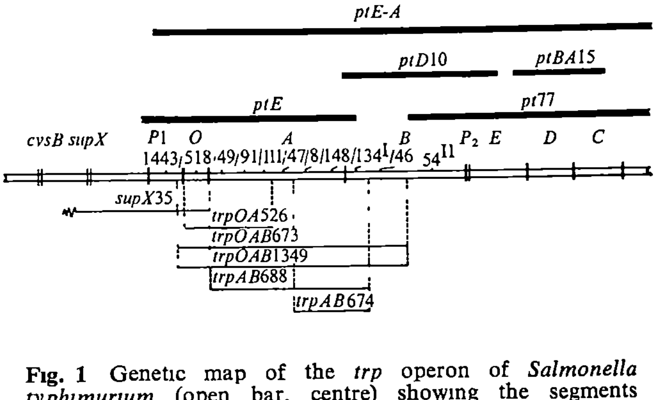

Fig. 1 Genetic map of the *trp* operon of *Salmonella typhimurium* (open bar, centre) showing the segments covered by the various multisite mutations used in this investigation (below bar) and the corresponding portions of the *trp* operon of *Escherichia coli* carried by transducing Ø80 pt phages used in hybridisation experiments (closed bars above map) The *trp* operons of both *E coli* and *S typhimurium* consist of five closely linked structural genes under tryptophan control[10,11] The order of these genes is the same in both organisms but the nomenclature is different that is the first structural gene, which codes for the anthranilate synthetase (AS) component of the AS-PRT complex, is designated *trpE* in *E coli* and *trpA* in *S typhimurium*[10,11] The numbers above the bar represent point mutations of the early portion of the operon and are shown in their map order[1,5,8] P1 represents the main *trp* promoter and P2 is the low-efficiency internal promoter-like element[21,27] The map indicates both regions of *trpB*, the gene for the anthranilate-PRPP-phosphoribosyl transferase (PRT) component of the AS-PRT enzyme complex region I codes for the glutamine transferase activity of this component, and region II for the PRT activity proper[26] The isolation of the multisite mutations is described in the text The isolation of *supX35* was described by Margolin and Bauerle[27]

The nomenclature used for the bacterial strains follows the recommendations of Demerec *et al*[15] For pulse labelling experiments cells (8 × 10^8 ml^{-1}) grown at 37° C in L broth were collected, washed twice with cold Vogel and Bonner's minimal medium[16] supplemented with 1% glucose and 0 25% casamino acids and resuspended in the same medium at an approximate concentration of 2 × 10^9 cells per ml Tryptophan (50 μg ml^{-1}) was added (repression conditions) or omitted (derepression conditions) as needed A 10 ml sample of the cell suspension was incubated at 30° C on a shaker for 10 min and then pulse labelled for 2 min with 10 μCi ml^{-1} carrier-free ^{3}H-5, 6-uridine (37 Ci mmol^{-1}) Labelling was stopped and the cells killed by pouring the culture immediately on to an equal volume of crushed frozen medium consisting of 0 01 M Tris-HCl buffer (*p*H 7 3), 5 mM $MgCl_2$, 10m M NaN_3, 400 μg ml^{-1} chloramphenicol, and 20% sucrose RNA was prepared by the phenol extraction method of Okamoto *et al*[17] except that the treatment with 0 5% sodium dodecylsulphate (SDS) and phenol was carried out at 4° C The RNA was precipitated with ethanol, dissolved in 0 5 M KCl, 10m M Tris-HCl buffer (*p*H 7 3) and filtered through a Millipore filter (0 45 μm pore size) After being further precipitated and redissolved by the same procedure, this purified ^{3}H–RNA was hybridised with denatured DNA of phage φ80 and the transducing phages described in Fig 1 30–50 μg of ^{3}H-RNA were used for each assay Bacteriophage DNA was prepared essentially as described by Morse and Yanofsky[18], with some modifications, heat denatured at 100° C for 20 min, rapidly cooled and bound to Millipore filters of 0 45 μm pore size (10 μg per filter) as described by Gillespie and Speigelman[19] and modified by Morse and Yanofsky[18] Hybridisation of ^{3}H-RNA to the filter-bound DNA was carried out in 0 4 ml volumes of 1× SSC (0 15 M NaCl, 0 015 M trisodium citrate) The reaction mixtures were incubated for 18 h at 65° C and cooled slowly to below 40° C The filters were then washed twice with cold 2× SSC, incubated for 30 min at 60° C in this buffer and rinsed twice with cold 2× SSC to reduce nonspecific binding, dried and the radioactivity determined in a liquid scintillation counter using a toluene base scintillation mixture No RNase treatment was used since this decreased considerably the number of counts hybridised in heterologous mRNA–DNA mixtures[7] The results given have been corrected by subtracting the counts retained on control φ80 DNA filters (about 20 c p m) Total radioactivity of ^{3}H-uridine incorporated into RNA (total ^{3}H-RNA) was measured as counts incorporated into cold TCA-precipitable material (~ 10^6 c p m) Tryptophan synthetase (TS) was assayed according to the procedure of Smith and Yanofsky[20] The β component of this enzyme was assayed in all strains except *trpD9*, known to lack it For this strain the α component was assayed Since both components of the tryptophan synthetase complex are repressed and derepressed in a coordinate fashion[21,22], the level of either of them can be used as an index of the level of expression of the *trp* operon Cells for the enzyme assays were grown in minimal medium[16] containing 0 5% glucose and 2 μg ml^{-1} casamino acids and supplemented with different amounts of L-tryptophan 50 μg ml^{-1} for repressing growth conditions, and 5 μg ml^{-1} for derepressing growth conditions Protein was determined by the method of Lowry *et al*[23] One unit of specific activity is defined as the utilisation of 0 1 μmol of substrate (indole) per mg protein at 37° C in 20 min[20] Specific activities are relative to those of repressed wild type (specific activity = 0 4) taken as unity

trp mRNA can hybridise to *E coli trp* DNA carried by transducing φ80 *pt* phages if certain modifications are introduced into the standard hybridisation procedure Under our conditions, hybridisation in the heterologous *S typhimurium* mRNA–*E coli* DNA system was about 67–75% of that in the homologous *E coli*–*E coli* system in good agreement with the results of Denney and Yanofsky Table 1 summarises some properties of our multisite mutants and the control strain *trpD9*, which carries a nonpolar mutation in the *trpD* gene All the strains in which the multisite mutation extends into the operator make tryptophan synthetase (TSase, EC 4 2 1 20) and *trp* mRNA constitutively, while in those which have an intact operator this enzyme and *trp* mRNA are under tryptophan control Table 1 also shows that the multisite mutants, (with the exception of *trpAB674*), have no detectable mRNA hybridising to the DNA of the phage *ptE*, but they do have detectable levels of mRNA hybridising to *pt77*, *ptBA15* and *ptD10* as well as *ptEA* DNA Since *ptE* carries only the DNA of the first structural gene of the operon, these are the results we would predict if the multisite mutations were deletions of the segment indicated in the genetic map (Fig 1) We would anticipate that *trp0A526* and *trpAB674* might contain some *trp* mRNA hybridisable to *ptE* DNA, but found a very small amount of it only in *trpAB674* We do not understand this observation yet, but it could be related to the decreased homology between mRNA and DNA in our heterologous system In any case, there is a distinct difference between *trpD9* and our multisite mutants in their content of *trp* mRNA hybridisable to *ptE* DNA

The *trp* mRNA of *E coli* is about 6,700 nucleotides long[8] and has a sedimentation coefficient of 33S in 5–30% linear sucrose gradients[9] Since the *trp* operons of *S typhimurium* and *E coli* are identical in overall organisation and the sizes of their protein products[10,11], we expect that the *trp* mRNA of *S typhimurium* will have the same sedimentation coefficient as that of *E coli* when centrifuged under the

Table 2 Transcription times (min) of various segments of the *trp* operon after the addition of rifampicin

		Transcription times (min) of segments hybridised to DNA of				*trp* mRNA

The experiment was carried out as described in the legend to Fig 3 Estimated sizes for the *trp* mRNA are based on transcription time. A value of zero indicates that no detectable ^{3}H-mRNA was found to hybridise to a particular *pt* DNA The predicted S values were obtained from a standard curve of S against molecular weight of various species of RNA based on figures obtained from the literature The observed S values were determined by the procedure described in the legend to Fig 2 same conditions This is indeed the case, as shown in Fig 2, for the *trp* mRNA of *trpD9* The mRNA molecule at the peak of the resedimentation profile (Fig 2*b*) sedimented at about 33S This *trp* mRNA could hybridise to *ptE* as well as *pt77* DNA, as expected from a normal polycistronic *trp* mRNA Figure 2*c* shows the resedimentation profile SO-584 (genotype *trpOAB673*) In contrast to *trpD9* the largest *trp* mRNA of this mutant sediments at 23S and does not hybridise to *ptE*, indicating that it is a transcript of only the distal portion of the operon The *trp* mRNAs of all our multisite mutants had smaller sedimentation coefficients than that of the control (Table 2), as expected if they contain deletions in the *trp* operon

Measurements of transcription time further support the idea that our multisite mutations are deletions of the proximal portion of the *trp* operon Rifampicin inhibits the initiation of transcription but does not interfere with transcription which is in progress A plot of the rate of ^{3}H-uridine incorporation after addition of rifampicin is linear[12] in agreement with the assumptions that (*a*) the distribution of RNA polymerase molecules transcribing the operon under derepression conditions is random, and (*b*) all polymerase molecules move at a constant rate Transcription time can then be obtained by extrapolation of the line expressing the rate of ^{3}H-uridine incorporation to the time axis[12] As Fig 3 shows, it takes about 4 66 min to transcribe the *trp* operon into *trpD9* For a mRNA which is 6,700 nucleotides long this corresponds to a transcription rate of 24 nucleotides per s, quite close to that calculated for *E coli* (25–28 nucleotides per s)[12] The figure also shows that the transcription time for the small deletions *trpOA526* and *trpAB674* is shorter (4 min) than that for *trpD9*, and that for the larger deletions *trpOAB637*, *trpOAB1349* and *trpAB688* is shorter still (about 3 5 min) Estimates of the size of the *trp* mRNA of each mutant based on these data are given in Table 2, and predicted S values for the respective *trp* mRNAs are compared with the observed ones The agreement between the estimated and the observed values is reasonably good

If ^{3}H-RNA is hybridised to the DNA of *pt* phages carrying different segments of the *trp* operon, such as *ptE*, *ptD10* and *ptBA15* (Fig 1) we can obtain additional evidence that the deletions are limited to the beginning (*trp-OAB*) portion of the operon Thus, if the first structural gene or parts thereof are missing, transcription of the second structural gene should end earlier in the mutant strains than in the control Results from these experiments are shown in Table 2 In *trpD9* synthesis of mRNA for the first gene (portion hybridisable to *ptE* DNA) is completed in 1 min, that for the second gene and early portion of the third (portion hybridisable to *ptD10 DNA*) is completed in 2 25 min, and the mRNA for most distal portion of the operon (hybridisable to *ptBA15*) is completed in 4 7 min,

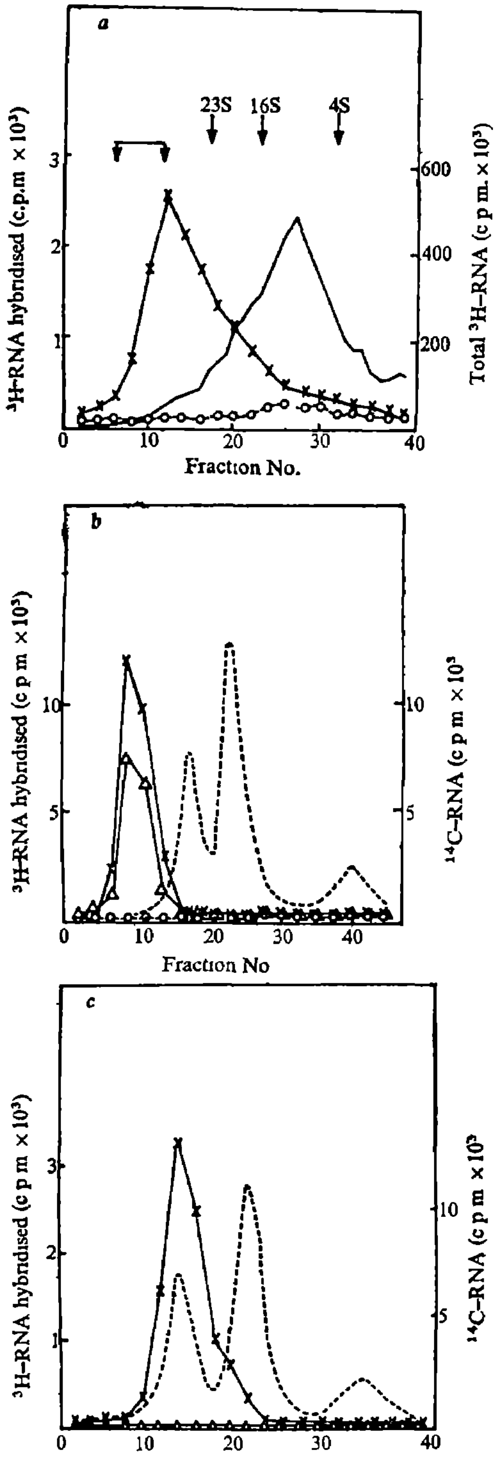

Fig. 2 Sedimentation (*a*) and resedimentation (*b* and *c*) profiles of *trp*mRNA of the mutants *trp*D9 and SO-584 *a*, The procedures used for pulse labelling, killing the cells and isolating ^{3}H-RNA are described in the legend to Table 1 Cells were labelled under derepression conditions (that is in the absence of tryptophan) The purified ^{3}H-RNA preparation (300–500 μg RNA, 4×10^6 c p m) was sedimented on a 5–30% linear sucrose gradient in 0 01 M Tris-HCl buffer (*p*H 7 3) and 0 05M KCl for 6 h at 36,000 r p m in a SW39 swinging bucket rotor of a L2-65B Spinco refrigerated ultracentrifuge Fractions of 10-16 drops were collected, and after adjusting the concentration of KCl to 0 5M, two neighbouring RNA fractions were pooled and 1/5 of each pooled fraction used for determination of the A_{260}, total ^{3}H-RNA counts and the hybridisation assay while the remainder was kept for resedimentation The hybridisation procedure is described in the legend to Table 1 X, counts retained on *ptEA*-DNA filters O, counts retained on φ80-DNA filters, ——, counts incorporated into cold TCA—precipitable material (total RNA) *b*, The bottom fractions containing the heaviest *trp* mRNA species (indicated by arrows in *a*) were combined and mixed with ^{14}C-rRNA prepared as described below All the RNA was then precipitated with ethanol, resuspended in H_2O, layered on a 5–30% sucrose gradient and centrifuged as described above After centrifugation, two neighbouring fractions were combined and hybridised with various DNAs The ^{14}C-rRNA was prepared by growing a strain carrying a deletion of the entire *trp* operon (*trpPOABEDC167*) under repression conditions (see legend to Table 1) and labelling with 50 μC of ^{14}C-uridine (52 7 mCi mmol^{-1}) for 3 h at 37° C. The cells were collected, washed twice and resuspended in 10 ml of the same medium After culture for 3 further hours, they were killed and the ^{14}C-RNA extracted by the procedures described in the legend to Table 1 ×, counts retained on pt77-DNA filters, Δ, counts retained on *ptE*-DNA filters, O, counts retained on φ80-DNA filters, – – – –, ^{14}C-RNA *c*, Resedimentation profile of the heaviest *trp* mRNA species of the mutant SO-584 (*trpθAB-673*) X, counts retained on *pt77*-DNA filters, minus counts retained on φ80-DNA filters, Δ, counts retained on *ptE*-DNA filters, minus counts retained on φ80-DNA filters; – – – –, ^{14}C-RNA.

ın good agreement with the results in Fig 3 (column 6 ın Table 2) The results obtained with the multisite mutants are ın marked contrast to those obtained with the control and clearly support the ıdea that they carry deletions ın the early portion of the *trp* operon The relative sizes of these deletions are ın good agreement with those indicated by the genetic data

If these deletions extend past *trpP1* and join the remainder of the *trp* operon to an outside promoter they should show no recombination ın crosses to the promoter mutation *trpP1443* (Fig 1) A full description of this mutation will be published separately (Angelosanto *et al* unpublished observations) Results of these crosses given ın Table 3 show that recombination occurs ın all cases and, as expected, is higher with deletion *trpAB688*, which does not extend into the operator, than with the others Of these *trpOA526* shows a higher recombination frequency than either of the two *trpOAB* deletions, which also make lower constitutive levels of both TSase and *trp* mRNA (Table 1) These results suggest that the *trpOAB* deletions extend partially into *trpP1* but *trpOA526* does not (Fig 1) A close examination of Table 1 reveals that while *trpOA526* makes between two and three times more *trp* mRNA than either *trpOAB673* or *trpOAB1349*, it synthesises between 20 and 30 times more TSase than the latter two deletion mutants Since *trpOA526* ends before *trpB* while the *trpOAB* deletions penetrate into *trpB*, the differences ın TSase levels observed these strains could be an indication that translation of the *trp* operon begins at initiators of different efficiencies ın these mutants

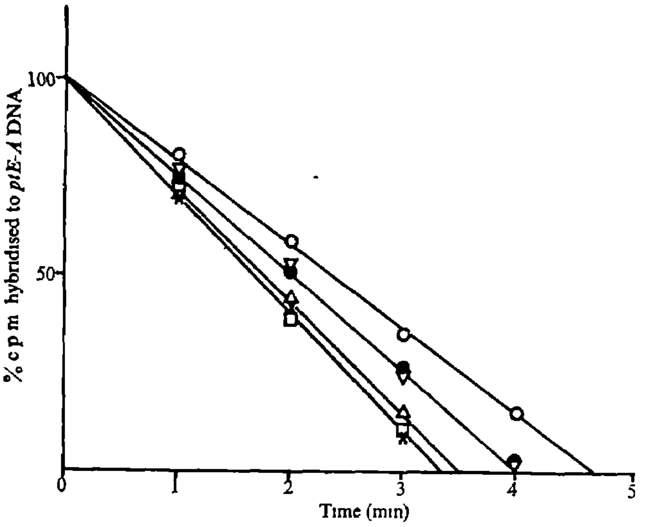

Fig. 3 Transcription of the *trp* operon after the addition of rifampicin Samples (4 ml) of overnight L broth cultures were used to inoculate 100 ml of fresh L broth, and the cultures incubated with aeration for 2 h at 37° C The cells were collected, washed with 0 03 M Tris-HCl buffer, *p*H 7 9, suspended ın 25 ml of the same buffer and incubated on a shaker for 2 min at 30° C At this point, 0 25 ml of a 0 1 M EDTA solution was added to the cell suspension, and incubation under the same conditions was continued for a further 2 minutes Pretreatment of the cells with EDTA ın Tris-HCl[28] made the cells susceptible to immediate inhibition by moderate concentrations (20 μg ml^{-1}) of rifampicin[29] At the end of this period, 75 ml of 4/3 strength Vogel and Bonner's minimal medium[16] supplemented with 1% glucose were added and incubation continued At the end of 10 5 min rifampicin (30 μg ml^{-1}) was added to the culture (time zero) Samples (10 ml) were removed at various times and pulse labelled for 30 s with ^{3}H-uridine (40 4 Ci mmol^{-1}) and killed as described ın the legend to Table 1 ^{3}H-RNA was isolated and hybridised with denatured DNA of *ptEA* transducing phage The percentage of c p m of ^{3}H-RNA hybridised is plotted at the midpoint of each pulse period after subtraction of the counts hybridised to φ80 phage DNA O, *trpD9*, ●, *trpOA526*, X, *trpOAB1439*, Δ, *OAB673*, ▽, *trp AB674*, ■, *trpAB688*.

Table 3 Recombination frequencies observed ın crosses between the promoter mutation *trpP*1443 and several deletions

Cross no	Recipient strain	Genotype	Frequency of recombinants 10^{-5}
1	SO-160	*trpOA*526	26
2	SO-441	*trpOAB*1349	3
3	SO-584	*trpOAB*673	1
4	SO-645	*trpAB*688	460

The crosses were carried out by transduction using the mutant L7 of bacteriophage P22 (ref 24) To increase recombination frequencies ın crosses 1, 2 and 3 the phage lysates were irradiated for 160 s with a GE germicidal bulb (15 W, polished reflector) at a distance of 60 cm These were optimal conditions for recombination, since phage lysates so treated showed a five-fold increase ın recombination frequency over unirradiated phage[25] In all crosses *trpP1443* was the donor and can grow slowly on minimal medium by forming pinpoint colonies after 48 h of incubation at 37° C Thus recombinants carrying *trpP1443* can be recognised by their typical phenotype The frequency of recombination is expressed as the number of prototrophs over total number of recombinants (prototroph + mutant) recovered In all cases, control platings of uninfected bacteria as well as phage lysates were carried out

All the results we have presented consistently indicate that, ın the *trp* operon of *S typhimurium*, the *trp* operator (*trpO*) and the trp promoter (*trpP1*) are essentially separable and arranged ın the order *P1-O* ın relation to the first structural gene *trpA* Brammar *et al* (personal communication) have reached the same conclusion for the *trp* operon of *E coli* Our data also show that deletion of most or part of *trpA* does not alter the regulation of the *trp* operon (that is *trpAB688* and *trpAB674*) but this is altered if the deletion includes *trpO* This gives further support to earlier findings[5,13,14] that the first structural gene of the *trp* operon does not play an essential role ın the regulation of the expression of the *trp* operon

We thank Drs C Yanofsky and Y Kano for suggestions and Drs A Matsushiro and C Yanofsky for transducing phages This work was supported by a grant from the US National Science Foundation

Observation of the 3_{12}–3_{13} transition of interstellar formaldehyde

Although several transitions of formaldehyde have been observed in interstellar space[1–7], there has been only one prior report of an observation of the 3_{12}–3_{13} transition[3] An energy level diagram of the lower rotational levels indicating the transitions that have been detected is given in Fig 1 The $\Delta J=1$ transitions are seen in emission The $\Delta J=0$ transitions are seen in absorption and emission[7–9] with a trend for the higher J transitions to be seen in emission (additional confirmation of this is provided by the unpublished work of B Turner who has seen the 4_{13}–4_{14} transition in emission) Here we report emission from the 3_{12}–3_{13} transition at 28 975 GHz in Sagittarius A (Sgr A)

Observations were made with the 4 57-m Cassegrain paraboloid at the University of British Columbia The receiver was operated in a beam-switched mode with the half-power beamwidth being 10′ The first stage of the receiver was a balanced mixer with a double sideband system temperature of 700 K In this work, however, losses from the switch, which was not operating at its centre frequency, and ground radiation degraded the system temperature by a factor of two Calibrations of antenna temperature were made using a gas discharge tube which in turn was calibrated using thermal sources at liquid nitrogen and ambient temperature Spectral line data were taken with a filter spectrometer having 32 contiguous channels each of 1 MHz bandwidth

The measured spectrum (Fig 2) is the average of two equal amounts of data one of which had been shifted in frequency by 3 MHz The data were obtained over seven nights of clear weather and represent 6 93 h of integration on Sgr A Also shown for comparison is an 'off-source' spectrum representing 6 58 h of integration The off-source data were obtained in exactly the same manner as the on-source data, except that the feed horns were covered by absorbing material because of poor weather The much larger noise on the formaldehyde spectrum is presumably due to fluctuations in atmospheric emission at the large zenith angle (~ 80°) at which we observe Sgr A The result we claim is an emission feature with a maximum antenna temperature of ~ 0 5 K centred at 0 km s^{-1} and extending about ± 30 km s^{-1} The significance of the result is 3 σ and so it should be treated with caution until confirmed by other observers The feature at −82 km s^{-1}, although almost as significant as the broad feature centred at 0 km s^{-1}, is dependent upon a single datum point and is probably a spurious signal The probability of this happening in a single channel is much higher than in five adjacent channels

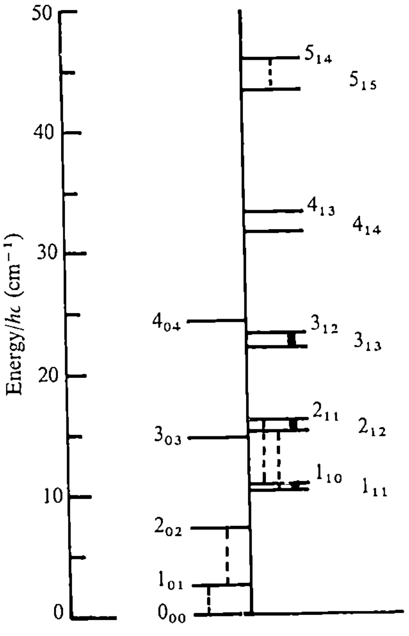

Fig 1 Observed transitions of H_2CO are indicated in the energy level diagram Transitions observed in emission are indicated by dashed lines while those observed in absorption are indicated by full lines

The velocity range covered by the emission line is somewhat different from the 6 cm formaldehyde absorption profile in Sgr A (ref 10) where the predominant absorption feature occurs over the range +20 to +65 km s^{-1} Other molecules such as NH_3 (ref 11), Xogen (ref 12), CO (ref 13) and CH_3 OH (ref 14) also give emission at positive velocities The 6 cm formaldehyde absorption profile, however, does have one component at 0 km s^{-1} but this is narrower than our emission result There is also agreement in velocity with the emission and absorption spectrum of HI (refs 15, 16) These agreements in velocity suggest a physical association of the emitting clouds

There are now nine different transitions that have been observed from $H_2{}^{12}C^{16}O$, but most of these have not been studied very extensively The 3_{12}–3_{13} line should be confirmed and more data should be obtained on the sizes and distribution of the $\Delta J=0$ emitting regions in order to have a clearer understanding of the factors involved in the excitation process

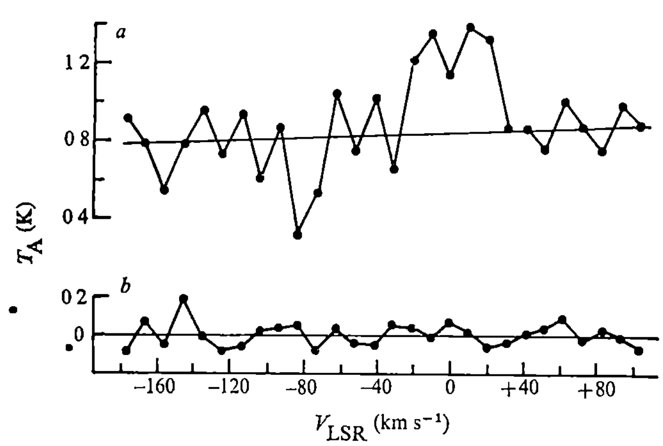

Fig. 2 Line profile of formaldehyde and control spectrum a, $J_k=3_{12}-3_{13}$, time 6 93 h, b, off-source, time 6 58 h

In the course of these observations we also searched for the $J_k=1_0-0_1$ transition of SO at 30 001 GHz in the molecular source in the Orion Nebula and obtained an upper limit to our antenna temperature of 0 2 K The 4_3-3_2 and 3_2-2_1 transitions have previously been observed[17], and if the column densities were the same at 30 GHz as at 99 3 GHz, we would expect an antenna temperature of 0 6–1 2 K Our upper limit implies an upper limit to the angular size of the SO emitting region ~ 5′ which is comparable to the sizes of the HII region and the H_2CO 2 mm emitting region

Evolution of the Moon's orbit and the origin of life

PERIODICITIES in fossil corals may be used to determine the number of days in a year[1], both daily and seasonal variations are visible in the growth patterns Scrutton[2] used similar data to determine the number of days in a lunar month, monthly and fortnightly periodicities are present because of tides The available data[3–6] through the Palaeozoic are given in Fig 1*a* and *b* We conclude, from studies of living crustaceans and recent fossils, that the growth patterns are sensitive to the solar day So, the data represent the number of solar days in a year and in a lunar month, the present values are 365 25 and 29 53 d respectively Panella[3] has also used periodicities in stromatolites to determine the number of solar days in a lunar month during the Precambrian His results are given in Fig 1*c*

Palaeontological data can be used to determine the past history of the lunar orbit[7–9] Assuming conservation of angular momentum in the Earth–Moon system the length

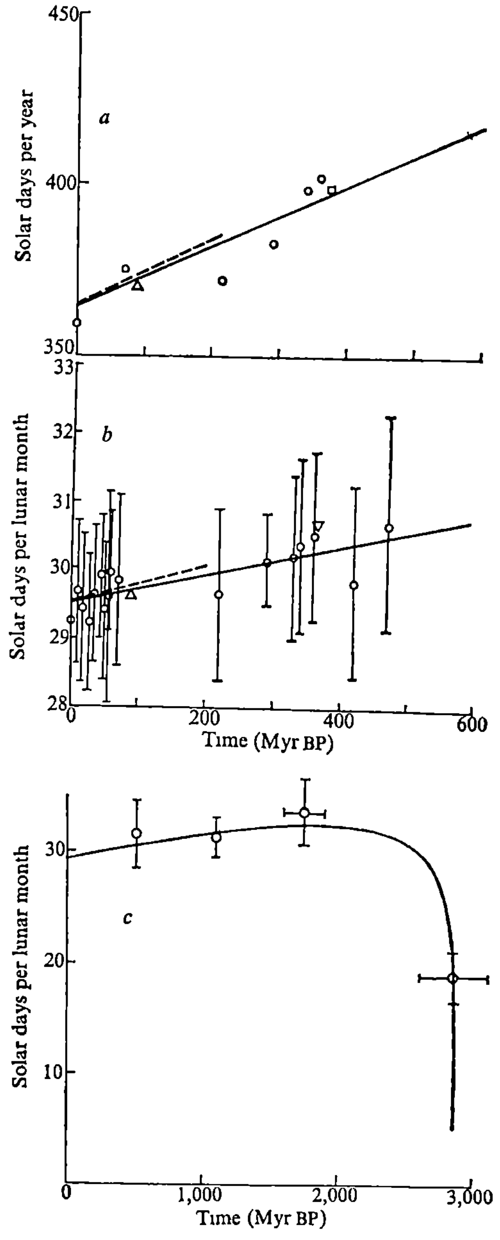

Fig 1 *a*, Data on the number of solar days in a year from molluscan shells is compared with the dependence we predicted and the value deduced from satellite observations (Newton[11]) *b*, Data on the number of solar days in a lunar month as in *a* Error bars are standard deviations of the data *c*, Data on the number of solar days in a lunar month from stromatolites (Pannella[3]) compared with the predicted dependence from our work The error bars on the counts are the standard deviations of the data, the error bars on the time are the stated errors on the dating of the fossils ○, Ref 3, □, ref 4, △ 5, ref 6, — — —, ref 11, ——, our results of the solar day and lunar month can be related, it is also assumed that the length of the year remains constant A lunar month cannot have more than 32 5 solar days (refs 8, 10) Because the Precambrian stromatolite data given by Panella[3] yield only monthly data, he could not show that the number of days in a month was not a multiple of the values given in Fig 1*c* But, the dynamical constraint on the number of days in a month places an upper limit which precludes, within the standard deviation of his data, an alternative interpretation of the data

With an assumption on the rate of tidal dissipation, the time evolution of the lunar orbit and length of day can be determined If the dissipation is proportional to the tidal force the rate of energy dissipation is proportional to the sixth power of the Earth–Moon separation Varying the single unknown parameter, the constant of proportionality between the tidal force and the tidal dissipation, the best fit to the data is given by the solid lines in Fig 1*a*, *b* and *c* In determining these curves the Bulawayan data at 2,850 Myr BP are critically important Without these data a close approach could not be predicted The counts of the Bulawayan growth patterns favour the 18 7 d month since there is a strong peak at 9 d corresponding to the fortnightly tides The alternative interpretation of a 37 4 d month falls outside the allowed maximum number of solar days in a lunar month even when the full standard deviation of the data is subtracted

The predicted value for the present tidal dissipation is $2\ 58\times10^{19}$ erg s^{-1} The corresponding value for the present acceleration of the moon is $n=-19\ 3$ and the value for the present acceleration of the Earth's rotation is $\omega=-934$ s $(100\ yr)^{-2}$ These values are in excellent agreement with the value for the acceleration of the Moon obtained from satellite observations[11] Newton's preferred value for the present lunar acceleration is[11] $n=-22\ 4$ s $(100\ yr)^{-2}$ and the corresponding changes in the number of solar days in a year and in a lunar month are given in Fig 1*a* and *b* Jeffreys[12] has reviewed the measurements of lunar acceleration and acceleration of the Earth's rotation and favours the value given by Newton The assumption that the dependence of the tidal dissipation on the tidal force is independent of time on the time scale of 10^9 yr certainly cannot be justified in detail But the resulting calculations are consistent with observation In Fig 2 the dependence of the Earth–Moon separation on time is given It seems that the Moon approached the Earth 2,850±250 Myr BP If the calculations of Gerstenkorn[13] are accepted this close approach was near the Roche limit for tidal catastrophe In any case, a near approach would result in very large tides and large energy dissipation Tidal heating could possibly have vaporised the oceans This has both geological and biological implications

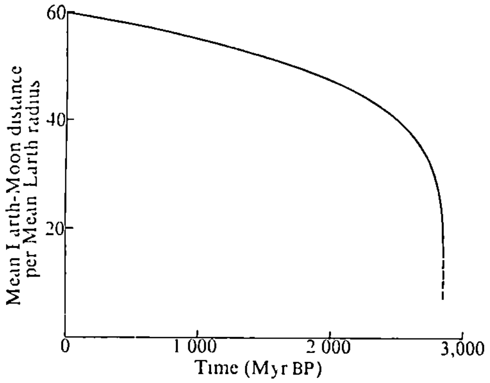

Fig 2 Predicted dependence of the Earth–Moon separation on time

There is evidence in the geological record[14] that a pulse of high temperature volcanism occurred about 2,800 Myr BP Many of the high temperature intrusions of ultrabasic rocks are dated at this time Such intrusions could be the result of tidal heating near the surface

The implied catastrophe roughly coincides with the first records of life The Onverwacht Series of southern Africa, which contains the first cell-like objects[15–18] is, contrary to earlier estimates[19], at least 3,000 Myr old (ref 20) and at most 3,200 to 3,300 Myr old (refs 21, 22) The oldest extensive Banded Iron Formation, one indirect indication of life[23], has been reliably dated[24] at no more than 3,000 Myr BP The earliest conclusive evidence for life is, in fact, the Bulawayan stromatolites[25–27] Though stromatolites generally form in warm waters, it has been suggested that many Precambrian-type stromatolites formed in scalding waters[28,29], which is consistent with the idea of thermal catastrophe It seems within the realm of possibility that a global thermal event might have been involved in the origin of life On a grand scale, one such event would resemble experiments performed by Fox[30,31] in which heating and cooling of 'organic soup' leads to the formation of remarkably cell-like coacervates

Relative abundances of positrons and antiprotons in the primary cosmic ray flux

SHEN and Berkey[1] calculated the ratio of antiprotons and positrons to be expected in the primary cosmic rays assuming that both components are the end products of proton–proton interactions, and pointed out that the observations of the positron spectrum would permit us to deduce the antiproton energy spectrum Observations on the ratio e$^+$/(e$^+$ + e$^-$) have been made[2] in the 5–50 GeV range, and we have used the results to put an upper limit on $\bar{p}$/p at various energies

Our calculations on the expected antiprotons-positron ratio differ in one significant respect from those of Shen and Berkey[1] we have detailed measurements of the cross section of antiproton production up to intersecting storage ring energies That permitted us to calculate the e$^+$/$\bar{p}$ ratio quite reliably

We have plotted the latest $\bar{p}$ and π^+ production cross-sections (Fig 1) They were deduced from the work of Antinucci *et al*[3] and Ramaty and Lingenfelter[4]

It has been shown[5 6] that $\langle E_{\bar{p}}\rangle/E_p$, the ratio of the mean energy of antiprotons, $\langle E_p\rangle$, to incident-proton energy, E_p is approximately 9, independent of the energy of the incident protons

This differs significantly from the results of Shen and Berkey[1] who found this ratio to vary as $E_p{}^{1/4}$ For the purpose of this calculation, we can summarise the results of the kinematics

$$\left.\begin{array}{l}\sigma_{\bar{p}}(E_p) \simeq 9\ 3 \times 10^{-3}(E_p - 10\ 8)\ \mathrm{mb} \\ \langle E_{\bar{p}}\rangle \simeq 9\ E_p\ \mathrm{GeV}\end{array}\right\} 20 \lesssim E_p \leq 550\ \mathrm{GeV} \tag{1}$$

$$\left.\begin{array}{l}\sigma\pi^+ (E_p) = 27\ 7\ E_p{}^{1/4}\ \mathrm{mb} \\ \langle E_{e^+}\rangle = 0\ 175\ E_p{}^{3/4}\ \mathrm{GeV}\end{array}\right\} 50 \lesssim E_p \lesssim 1{,}500\ \mathrm{GeV} \tag{2}$$

Following a procedure analogous to that of Shen and Berkey[1] we found that the ratio of the production spectrum of positrons to antiprotons can be written as

$$\frac{Q_{e^+}(E)}{Q_{\bar{p}}\ (E)} = \frac{6\ 176 \times 10^{-2}\ E^{-0\ 586}}{2} \times \frac{\sigma_{\pi^+}[(22\ 86E^{4/3})]}{\sigma_{\bar{p}}(9E)} \tag{3}$$

which gives rise to values for the ratio e$^+$/$\bar{p}$ of 4 at 5 GeV and 1 56 at 10 GeV These values depend on the spectral index of the differential proton energy spectrum only, taken to be 1 9 × $10^4 E^{-2\ 75}$m^{-2} sr^{-1} s^{-1} GeV^{-1} (refs 7 and 8) The factor of two in the denominator comes from the decay of antineutrons in space

The equilibrium value of e$^+$/$\bar{p}$ will depend on the actual model of propagation and would tend to lower somewhat the ratio e$^+$/$\bar{p}$ Similarly, if the leakage mean free path is energy dependent this ratio will again be lowered We will ignore these effects for the present and assume that the production and equilibrium values are the same They will change the ratio by a factor of two or less

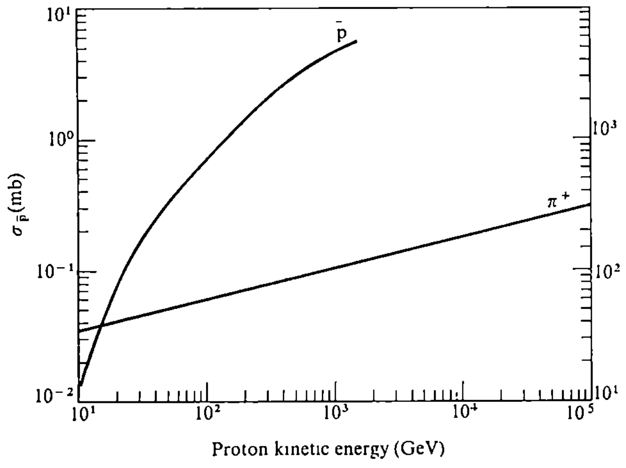

Fig. 1 The production cross sections of π^+ (scaled down by a factor of 1 5) and $\bar{p}$, as a function of proton kinetic energy in proton–proton collisions

We interpret the results of Buffington *et al*[2] as indicating an upper limit of 10% on the ratio e$^+$/(e$^+$ + e$^-$) in order to obtain an upper limit on p/p That gives an upper limit on the e$^+$ energy spectrum when combined with the measurements of (e$^+$ + e$^-$) as summarised by Muller and Meyer[9] Thus,

$$\mathrm{p/p} \lesssim 1\ 8 \times 10^{-4} \text{ at 5 GeV}$$
$$\lesssim 5\ 7 \times 10^{-4} \text{ at 10 GeV}$$

which, even after allowing for propagation uncertainties, is about an order of magnitude lower than the value of 6 × 10^{-3} obtained by Bogomolov *et al*[10] in a larger GeV range

As the e$^+$/p ratio produced in nuclear reactions is very well known, measurements of e$^+$/p (in conjunction with knowledge of the proton flux itself) depend only on the amount of e$^+$ from cosmic ray sources and on the energy dependence of the storage time of primary protons in the galaxy Comparison of e$^+$ and p fluxes would be extremely valuable in the understanding of cosmic ray production and propagation

Will there be a large earthquake in central California during the next two decades?

P-VELOCITY decreases before earthquakes[1–4] can be observed by monitoring the average P-residual at seismic stations near the focus[5–7] The P-residual is the difference between the observed travel time from an epicentre to a station and that computed theoretically on the basis of some Earth model and a least squares estimate of the earthquake location and origin time If the P-velocity in the crust underneath a seismic station is decreased temporarily, each seismic wave will arrive somewhat later during the premonitory period Before three thrust[5,6,18] and one strike-slip event[7] the delay was found to be approximately 0 4 s

Here I compare the average teleseismic P-residuals of four stations located near the San Andreas fault (Berkeley, BKS, Mt Hamilton, MHC, Priest, PRI, and Pasadena, PAS) to those of three stations to the East of it (Mineral, MIN, Jamestown, JAS, and, Golden, GOL) (Fig 1) Since our interest is focused on the detection of precursor anomalies lasting several years (earthquake magnitudes ⩾6 5) Fig 2 shows annual mean residuals The standard deviations of the annual means are approximately 0 1 s for 1961–63, and 0 07 s to 0 04 s since then, shown by error bars in the figures.

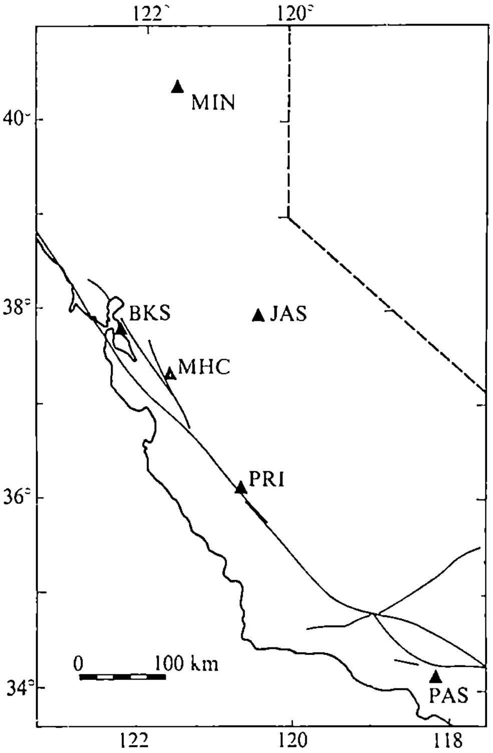

Fig. 1 Map of California showing the locations of seismic stations with respect to the San Andreas fault The station Golden is located in Colorado at 39° 42′N and 105° 22′W

The constancy of the average P-residuals in Fig 2 is surprising compared with other data[5-7] where fluctuations of 0 15 s are quite common and where precursor anomalies have amplitudes of 0 4 s Only stations PRI and PAS show disturbances of more than 0 2 s from the long term mean Both disturbances accompanied earthquakes near those stations All curves except that for MIN show an increase of approximately 0 2 s in the mean annual P-residual in 1969 Clearly the increase in 1969 was due to changes in the earthquake locating procedure, since a similar change occurs at stations in other parts of the world Therefore I assume that the stations GOL, JAS and MIN are in a different tectonic region than the San Andreas stations and thus these three observatories can be used as control stations

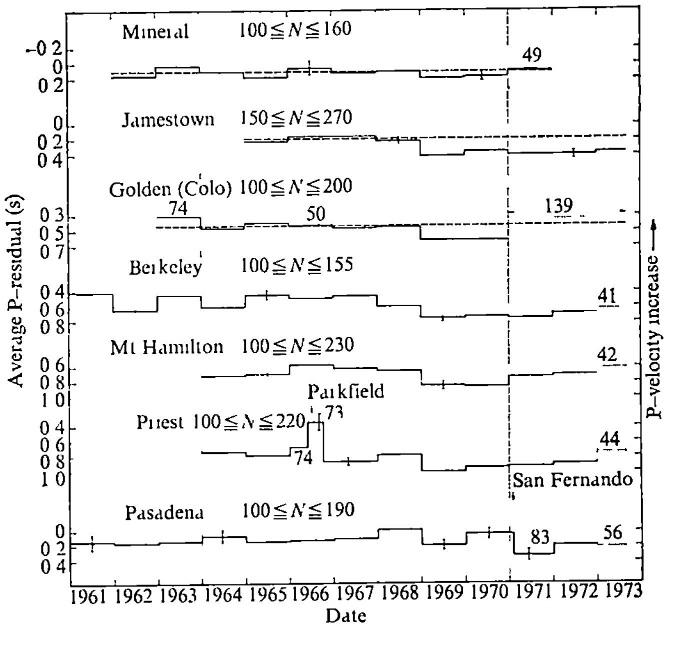

Fig 2 Mean annual teleseismic P-residuals from 3 reference (top) and 4 tectonic (bottom) stations Dashed lines, long term average through 1968 Arrows indicate time of occurrence of local earthquakes Vertical dashed lines separate different data sets The data for the years 1961–1963 are from ref 8, those for 1964–70, from ref 9, and those for 1971–73, from ref 10 All residuals used were from earthquakes with depths ⩾ 100 km, located at distances ⩾ 15° whose hypocentres were determined on the basis of more than 25 readings and with absolute values smaller than 3 s.

Errors related to the seismic source, the teleseismic ray path, or the data procurement procedure are reduced by taking the difference between the average residuals at different stations (for details see ref 6) Each tectonic station was compared simultaneously to as many of the three control stations as were operating each year For this purpose a correction factor was computed which was the average of the control station deviations from their respective long term means The average residual minus the correction factor is shown in Fig 3

The stations BKS, MHC, PRI and JAS are operated on a common time base by the University of California, Berkeley, and the same observer reads the arrival times at all stations For these stations the comparison with the control station JAS will therefore be especially effective in reducing all errors except the effects of changes in the local crust and the unlikely possibility of changes in the instrument characteristics The corrected P-residuals shown in Fig 3 are very stable with deviations from the respective long term means of less than 0 13 s for all years, except at the times of the Parkfield and San Fernando earthquakes (The averages for 1973 do not contain enough data points to be considered reliable)

The decrease of the average residual at PAS before the San Fernando earthquake suggests that PAS was located just outside the dilatant region which preceded this earthquake[3], and that the crustal P-velocity under PAS increased temporarily This may have been a consequence of stresses generated by the dilatancy closing rock pores at the periphery After the earthquake a somewhat lower than average velocity is indicated by the P-residuals This may have been due to partial dilatancy outside the source region caused by the redistribution of stress associated with the earthquake Such an effect is expected from laboratory experiments[13] and was observed for the 1966 Gisborne earthquake in New Zealand[6] The results presented for PAS are in agreement with the constancy of the P-velocity as determined from records of quarry blasts[16] and individual teleseisms[17]

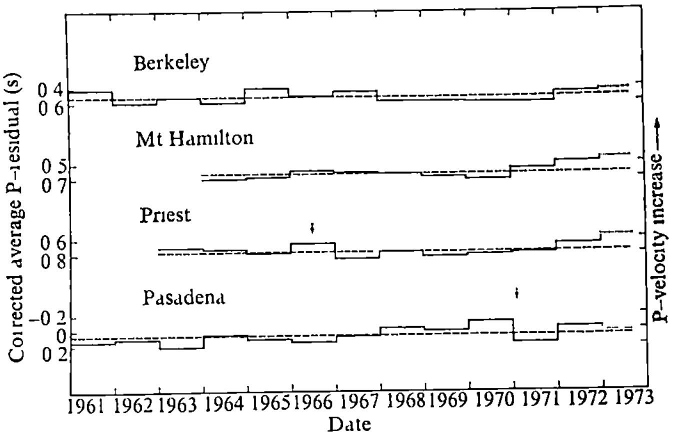

Fig. 3 Corrected annual mean residuals for 4 tectonic stations

From Fig 3 it is clear that, except for the minor perturbations discussed above, there is no significant change in P-velocity in a vertical direction beneath any of these stations. McEvilly and Johnson[14] concluded from explosion studies that there was no variation in both the P and S-velocities in a horizontal direction in central California. In addition they found v_p/v_s to be normal.

The absence of a P-residual anomaly in central California can be interpreted to mean that strike-slip tectonism does not produce significant precursory changes in the seismic velocity. But it seems that the P-residuals increased before the strike-slip earthquakes at Sitka, 1972 (ref. 7), and at Bear Valley, 1972 (ref. 15). These two observations suggest that the above interpretation of the data may not be correct. Since magnitude 7 and 8 earthquakes are expected to be preceded by anomalies lasting 7 and 25 years respectively[3,12], the data presented here and in ref. 14 suggest that no earthquake of $M>7$ and no earthquake of $M\approx 8$ will occur between San Francisco and Parkfield, California during the next 7 and 25 yr, respectively.

I thank W. E. Farrell, C. Kisslinger and H. Spetzler for suggestions.

Is Kakangari a unique chondrite?

THE Kakangari meteorite, possibly a unique member of a distinct chemical class of chondrite, fell in India in 1890. Two stones were seen to fall, and though one was soon destroyed the bulk of the other, about 310 g, is preserved in Calcutta and London[1,2]. Mason and Wiik[3] concluded that Kakangari is probably a carbonaceous chondrite. Subsequent improved understanding of chemical fractionation between chondritic groups (see ref. 4) enables us to show, however, that their analysis in fact indicates that Kakangari is similar in bulk composition to the ordinary chondrites, apart from its high S content (Table 1). In this last respect it resembles carbonaceous or enstatite chondrites. The FeO × 100/(FeO + MgO) molecular ratio, 13.7, lies between that of H group (bronzite) chondrites and enstatite chondrites. That is confirmed by our microprobe analyses discussed here. The mineralogical data are based on preliminary microprobe analyses on a thin section cut from a British Museum (Natural History) specimen (BM 69062).

Table 1 Composition of chondrites*

	C†	O	K	E
Mg	10,500	9,500	9,900	7,500
Ca	730	480	489	355
Al	850	610	726	480
S	5,000–1,200	1,000	2,800	3,000–1,500‡

*Atoms per 10^4 Si atom.
†C, carbonaceous chondrites, O, ordinary chondrites, K, Kakangari, E, enstatite chondrites.
‡The high figures are for C1 and E3, 4, respectively. Kakangari data from ref. 3, the remainder from ref. 12.

Olivine is apparently less abundant than pyroxene. Analyses of 26 grains from 15 locations show the compositional range to be $Fa_{3-9.5}$, the grains have less than 0.1% CaO (weight) and in this respect are similar to the olivines of ordinary chondrites[5] and distinct from those of carbonaceous chondrites[6]. Mason[3] used a diffractometric method to determine the composition of Kakangari olivine and from the skewed peak he obtained, suggested that the olivine is dominantly forsteritic with some scatter towards more iron-rich compositions, perhaps Fa_{25}. Our microprobe work does not substantiate this and an X-ray powder photograph shows that the groundmass is dominantly enstatite with some troilite. That eliminates the groundmass as a possible source of olivine, as in type III carbonaceous chondrites. In any case, the compositional distribution of Kakangari olivines is more limited than in type III carbonaceous chondrites[7], it lacks a peak at Fa_1 or the more Fe-rich grains to Fa_{50} or more. The mean olivine composition in Kakangari—$Fa_{4.9}$—is, however, close to that of the carbonaceous chondrite Vigarano, $Fa_{5.6}$ (ref. 7).

Fifteen analyses of pyroxene from 11 locations indicate that the compositional range is $Fs_{4.6-14.5}$, with the wollastonite component from $Wo_{0.2-6.6}$, grains from 7 of the 11 locations (a location is a chondrule or grain in matrix) were in the range $Fs_{4.5-5.5}$. The mean pyroxene composition is $Fs_{6.9}$ and is similar to that of carbonaceous chondrites (ref. 7).

Troilite is ubiquitous, occurring as grains and veins in chondrules, and as grains or fine grained material in the groundmass. Its Ni content is less than 0.2% by weight, but grains in the groundmass have 0.19 ± 0.05% Cr (weight) and a grain in one chondrule has 0.43 ± 0.05%. The Ti content is less than 0.05%. Kamacite occurs within chondrules, as rims ('armour') to chondrules, and as grains in the matrix. Ni and Co contents are close to 6% and 0.7% (weight), respectively. In our cursory examination, taenite was not found in the matrix, but it commonly occurs as grains in chondrules. Most grains have a fairly uniform Ni content in the range 29–32%, but one zoned grain has a core with 26% increasing to 31% or more at the rim, indicating some attempt at equilibration during falling temperature[8]. Taenite has a Co content of about 0.31%, and will be studied in greater detail.

This meteorite has a state of reduction between that of the H group (bronzite) chondrites and enstatite chondrites. In ordinary chondrites, Cr is lithophile, the sulphide containing not more than a few hundred p.p.m. of this element (ref. 9, and C. J. Elliott, personal communication) but in the enstatite chondrites, the troilite has about 1% Cr by weight and the remainder of this element occurs as the sulphide, daubreelite[10]. In enstatite chondrites, Ti, is also largely chalcophile, the bulk, about 75%, occurring as a minor constituent of troilite[11]. The presence of significant Cr and absence of Ti in the Kakangari troilite thus indicate a state of reduction between that of enstatite and ordinary chondrites. This conclusion is also supported by the oxidised Fe content of the olivine and pyroxene; the enstatite chondrites have almost no Fe in the silicate[10] whereas ordinary chondrites have olivines and pyroxenes in the range Fa_{16-33} and Fs_{14-25}, respectively (6). The mineral chemistry thus supports our interpretation of Mason and Wiik's[3] bulk chemical analysis as indicating that Kakangari represents a class of chondrite previously unrecognised.

Because it is apparently unique, the limits (if any) of the chemical properties diagnostic of its class cannot yet be determined. Although closer to the L group of ordinary chondrites with regard to its low (22.47%) total Fe content, its oxidation state indicates a closer relationship with the H group. It is chemically distinct from enstatite and carbonaceous groups. Perhaps it is best to consider this stone as representative of a K group of chondrites, the diagnostic properties of which are undefined.

A. W. R. and J. C. Bevan, and R. F. Symes, are thanked for sample preparation or help with microprobe analyses. E. E. Fejer arranged the X-ray powder photograph.

Note added in proof: We now realise that Kakangari may be chemically related to the recrystallised chondrite Mount Morris (Wisconsin), to the silicate portion of the stony-iron Winona, and to chondritic xenoliths in the achondrite Cumberland Falls; we have begun to investigate this.

A Cretaceous guyot in the Rockall Trough

THE Anton Dohrn seamount[1,2] is situated in the central part of the Rockall Trough (Fig. 1). The feature is of some interest in view of its relatively isolated position in the trough and because it has an almost flat summit, a rare characteristic for a seamount in the North Atlantic. Because it has received little attention since its early bathymetric survey, we took the opportunity of recording magnetic and seismic profiles over it and also carried out a preliminary sampling investigation in the area during a recent cruise of *RRS John Murray*. In this contribution we report some of our findings and discuss their significance in relation to the history of the region.

The seamount possesses a strong magnetic signature (Fig. 2) in marked contrast to the main part of the Rockall Trough which is magnetically quiet[5,6]. The high amplitude, short wavelength anomalies, together with the general shape of the seamount, are consistent with its being a volcanic feature. It is clearly different in composition and origin from the nonmagnetic Galicia Bank[7], another flat-topped seamount which is situated close to the European continental margin near 43°N. Seismic profile A_1–B_1 in Fig. 3 reveals the presence of a capping of sediments which, assuming an average sedimentary sound velocity of 2.0 km s^{-1}, reaches a thickness of over 100 m. Although the seismic evidence is not unequivocal, the contact between the sediments and the main volcanic pile appears to be defined by the reflector labelled X, the major break in slope on the seamount occurring where this horizon outcrops. A 200 kg haul of rocks obtained by dredging the steep slope just below the bench at which reflector X is exposed (site 4, Fig. 1.) supports this interpretation. Over 60% by weight of the material recovered consists of ahermatypic corals (mainly *Lophelia prolifera*) and not unexpectedly, exotic blocks of glacial origin. The remaining fraction is made up of basic lavas and tuffs, many being highly altered and very friable, which are considered to have come from outcrops situated along or close to the path taken by the dredge. The composition of the central portion of the largest block of lava, one weighing 38 kg, is given in Table 1. This is a basalt of alkaline affinities which is predominantly made up of plagioclase feldspar (An_{68}–An_{72}), together with augite and hornblende, the latter replacing the pyroxene. Unfortunately, the extent of the alteration makes it unsuitable for radiometric dating.

Even though the basic volcanics are far from fresh they have proved to be of considerable interest, because chalk was found adhering to several specimens. The chalk either occupies vesicles, as in the case of the 38 kg block, or it occurs as a matrix between highly altered, angular and sometimes vesicular clasts of basalt (see Fig. 4). Despite its intimate association with the lava, the sediment shows no evidence of baking. The chalk contains abundant nannofossils whose preservation is, unfortunately, somewhat marred by calcite overgrowths. Nannofossil assemblages are assigned to the *Nephrolithus frequens* Zone of Cepek and Hay[8] which Manivit[9] considers to be Upper Maestrichtian in age, correlating it with the *Globotruncana contusa* foraminiferal zone. The following species were recorded: *Nephrolithus frequens, Lithraphidites grosspectinatus, L. carniolensis, L. quadratus, Tetralithus murus, T. quadratus, Markalius astroporus, Lucianorhabdus cayeuxi, Ceratolithoides kamptneri, Cylindralithus serratus, Rhabdolithina splendens, Reinhardites anthophorus, Microrhabdulus stradneri, Cretarhabdus decorus.* The scarcity of members of *Lithraphidites quadratus* and *Nephrolithus frequens* together with the absence of pentaliths suggests an open ocean assemblage[10,11].

The time of formation of the Anton Dohrn seamount cannot be determined with any certainty without more extensive sampling but the discovery of Maestrichtian chalk so closely associated with the volcanics points to an Upper Cretaceous age. The chalk may indeed be the earliest sediment to be deposited on the seamount. Evidently, the feature was not created at the time of the main separation of the Rockall Plateau from Europe because it is characterised by large magnetic anomalies whereas most of the Rockall Trough is magnetically quiet. The Cretacous age and the spatial relationship of the Anton Dohrn seamount with respect to the volcanic centres in north-east Ireland and Scotland make it difficult to envisage the feature as part of the scar trace of the mantle plume postulated by Duncan and others[12] to explain age variations in the Thulean province. It is, perhaps, more likely to be related to the lithospheric heating and general tensional conditions in the crust which immediately preceded the development of new ocean basins to the west and north of the Rockall microcontinent.

An appreciable proportion of the seamount was removed by erosion following the main volcanic activity, the even surface of reflector X probably being the level to which erosion extended. The central knolls (Fig. 1) are possibly remnants of resistant feeder channels within the volcano.

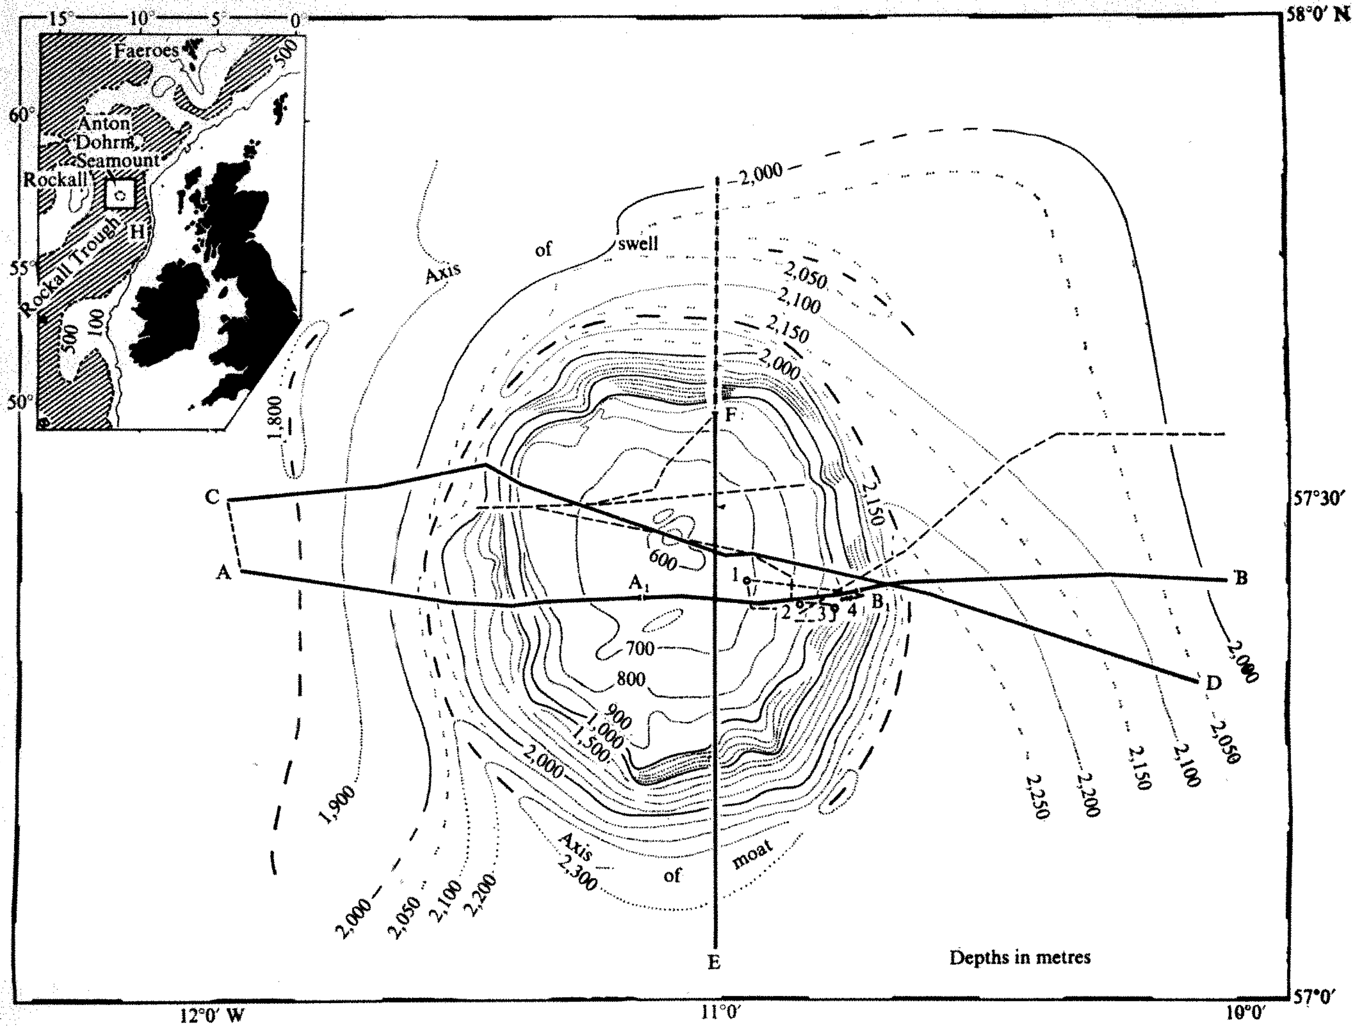

Fig. 1 Tracks of *RRS John Murray* shown on a bathymetric map of the Anton Dohrn seamount, taken from Dietrich and Ulrich[2]. Water depths are corrected for sound velocity variations in sea water using the tables of Matthews[3]. Profiles along portions of the track indicated by heavy lines are reproduced in Figs 2 and 3. Positions of core stations 1–3 and dredge site 4 on the eastern side of the seamount are indicated. The moat and swell around the seamount arise from non-uniform deposition of sediments controlled by the pattern of bottom currents[4]. H = Hebrides Terrace.

Similar features have also been recognised on some of the Pacific guyots[13]. A comparison of the shapes of volcanic islands and the Anton Dohrn seamount suggests that it originally stood at least 2 km above sea level. After the period of planation the volcano sank over 600 m. Its present, southeasterly tilt (Figs 2 and 3) may have been acquired at this time or it may reflect subsequent loading of the crust by thick sediments which airgun profiles indicate lie beneath the lower part of the continental slope between the seamount and the Hebrides Terrace (H in Fig. 1).

Coring was carried out upslope from the dredge site (stations 1–3; Fig. 1) to determine the time and rate of sinking of the seamount from the stratigraphy of the sediment layer above X. According to the seismic profiles, reflectors normally lying within the layer are exposed there. Unfortunately, the corer failed to penetrate a cover of stiff Glacial or post-Glacial shelly and silty clays so, at present, we can only assign a tentative date for the subsidence from what is known about vertical movements in the surrounding areas. In this region of the North Atlantic there is evidence for at least one major phase of regional subsidence in post-Cretaceous time. Seismic profiles from the continental margin west of Britain reveal a widespread unconformity, believed to be of early Tertiary age from a limited amount of stratigraphic data, which appears to have resulted from erosion followed by downwarping of the margin and outbuilding of the continental slope[14,15]. To the west of the Rockall Trough the sedimentary record of the Rockall Plateau provides convincing evidence of early Tertiary subsidence. The lithological variations at DSDP site 117 show that at least part of the plateau sank 600–700 m in late Palaeocene–early Eocene times at an average rate of 14 cm per 1,000 yr (ref. 16). Although the movements to the east and west of the Rockall Trough may not have been synchronous, there is general agreement that an important episode of subsidence took place between the late Cretaceous and Oligocene, possibly related to cooling of the lithosphere in this region following the birth of the Reykjanes Ridge and the early Tertiary igneous activity in the Rockall and Scottish areas. It seems probable that sinking of the Anton Dohrn seamount is yet another manifestation of these early Tertiary crustal adjust-

Table 1 Analysis of basalt dredged at site 4

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	Na_2O	K_2O	H_2O	TiO_2	P_2O_5	MnO	CO_2	Total
%	39.80	15.13	10.09	2.08	5.34	13.64	2.21	0.60	4.76	1.53	0.46	0.18	3.94	99.76

ments and is also an indicator of appreciable subsidence of much of the Rockall Trough at this time.

A proposed γ camera

ISOTOPES which emit γ rays are used for clinical diagnosis. This has led to the development of image forming systems which are based on detectors placed in the proximity of a radiating source, allowing abnormalities such as tumours and gross lesions to be detected.

As γ rays cannot be focused, the formation of an image depends upon an estimation of particle trajectories. Generally, this necessitates the elimination of all trajectories outside a narrow range of incidence angles. This has been achieved using lead collimators. Such systems give directional information but do not indicate the distance from the detector to the source point. Clearly only two-dimensional images can be obtained. Using a collimated scintillator and photomultiplier system severely limits the use of the cameras. We here outline a completely different approach to the principles of γ-ray imaging, which seems to offer considerable advantages over existing systems.

Scanners or cameras can be used. The scanner has a detector head consisting of a scintillation crystal, a photomultiplier and a lead diverging hole collimator. The complete image forming process can take up to 30 min. In camera systems the collimated detector must cover the entire region of investigation. Mechanical scanning is not used and the scintillation positions are detected using an array of photomultipliers. This principle is adopted in the widely used Anger system[1]. The interactions used in image formation are single absorption processes which result from the photoelectric effect.

In both scanner and camera imaging, speed can be increased with greater isotope activity. With a lead collimator only a small fraction of the incident radiation is useful. Also, with low energy isotopes (< 500 keV), there is considerable scattering within the examined region. There are thus inherent limitations in resolution and sensitivity.

The Compton effect is associated with multiple interactions. The position and intensity of these interactions define, within statistical limits, the trajectory of the incident photon. In principle this would allow projection back on to an image plane (Fig. 1). If the coordinates, $\mathbf{x}_1$ and $\mathbf{x}_2$, of the first two consecutive interactions are measured, and if the scattering angle, α, is known then the emission point must lie on the surface of a cone defined by all lines at angle α to the vector $\mathbf{x}_1 - \mathbf{x}_2$ through $\mathbf{x}_1$. The intersection of this cone with an image plane, generates an ellipse with parameters which are functions of $\mathbf{x}_1$, $\mathbf{x}_2$, and α. $\mathbf{x}_1$ and $\mathbf{x}_2$ can be measured directly using an array of detectors, which also give an indirect estimate of α from the energy loss, δE, at the first interaction:

$$\cos \alpha = (E - k\delta E) \,/\, (E - \delta E)$$

where E = initial source energy, and $K = 1 + (mc^2 \,/\, E)$, constant for a particular source.

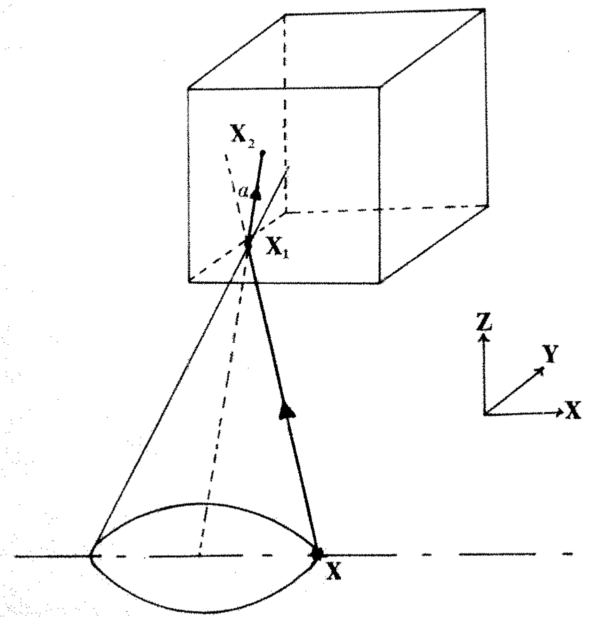

Fig. 1 The Compton γ camera principle.

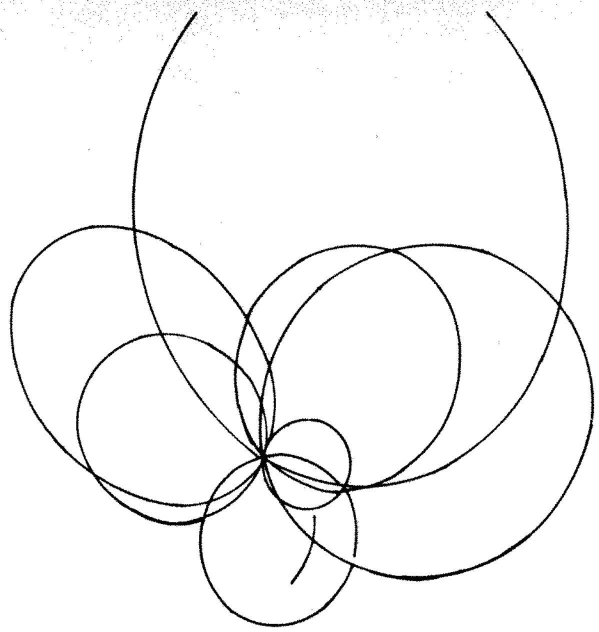

Fig. 2 Ellipses generated from a point source.

If a single point source of activity is considered, a succession of emissions will generate a number of ellipses which have a common point of intersection, thereby defining the image point (Fig. 2). The image of a radiating body consists of many small elements, each representing a small area of the source. The size of the elements is, therefore, chosen so that there are sufficient emissions from each to produce a statistically stable image. The simplest image which can be formed is by direct summation of all the ellipses produced. Generation of each ellipse involves the computation of coordinates, $\mathbf{x}$ from the equation relating the scalar product of the two vectors, $(\mathbf{x}_1 - \mathbf{x}_2)$ and $(\mathbf{x} - \mathbf{x}_1)$, to the scatter angle, α. For convenience this equation is written as

$$\cos \alpha = \overline{(\mathbf{x}_1 - \mathbf{x}_2)} \,.\, \overline{(\mathbf{x} - \mathbf{x}_1)} \qquad (2)$$

where a bar denotes a unit vector.

Vector $\mathbf{x}$ must also be constrained to lie in the image plane defined by

$$\mathbf{a} \,.\, \mathbf{x} = b \qquad (3)$$

The image plane is defined only by the parameters, a, and b, in equation (3), and so the choice of the depth and inclination of the plane is arbitrary. It is possible to project images on to a multitude of planes using the same set of measurements, and even to superimpose them to obtain three-dimensional images.

Figure 3 shows a schematic diagram of the proposed imaging system. There will be errors because of noise in the amplifiers, and because of quantisation and round-off into the digital processor. The basic source of error is, however, the detector, which is analogous to the lens in a normal optical system. As it is envisaged that the system will be able to cope with changes in the source distribution, the dynamic aspects of these errors are of considerable importance in relation to the design of the components.

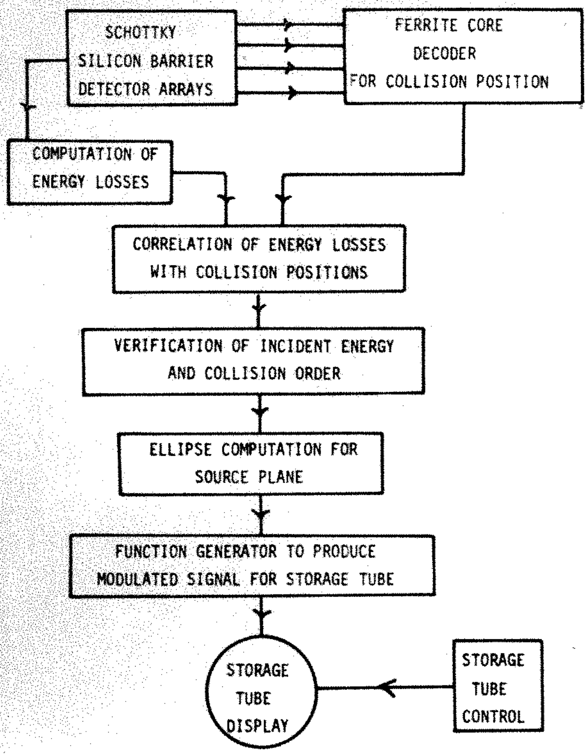

Fig. 3 Schematic representation of the proposed system.

The detector must be capable of measuring the coordinates and intensity of an interaction, and liquid or solid scintillators, proportional chambers and semiconductor detectors would be suitable. Energy resolution, response time and transmission properties suggest, however, that the latter offers the best solution and a prototype is under construction, based on a lattice of Schottky barrier orthogonal arrays of 0.5 mm cubic elements. Because the device uses Compton scattering, it is not necessary to use high atomic number detectors working at very low temperatures.

It is normal in image processing to define the optical accuracy in terms of a point spread function; a complete image is the result of convolution with source distribution. In collimator systems there is a one–to–one correspondence between source points and a mean point on the image plane. The point-spread function gives the statistical spread about this mean. In the proposed system a source point generates a deterministic ellipse on the image plane, in the absence of measurement errors. It is possible to determine the statistical spread, resulting from measurement errors, about the ellipse. This distribution is not, however, directly useful in an assessment of image formation and, in practice, each image point is obtained by an accumulation of ellipses. It is therefore more appropriate to define a point spread function for the sum of ellipses about their common point of intersection. Figure 4 shows the theoretical point spread function assuming the source to be 10 cm from the detector. This is a more pessimistic estimate than the so-called intrinsic point spread function.

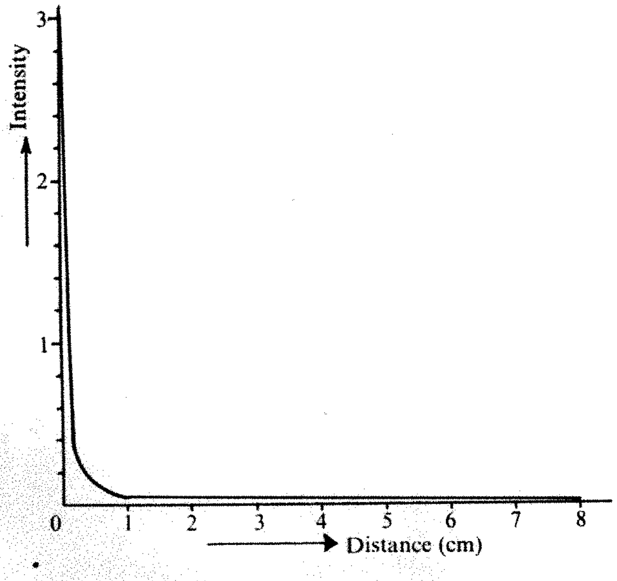

Fig. 4 Point spread function of the Compton camera.

The point spread function used here assumes statistical stability. That is, the addition of further ellipses does not improve the function. Although this results in a sharp distribution, it is fair because comparisons with other systems allow consideration of the number of counts necessary to form an image. In more conventional measurement terms this is concerned with the relationship between signal : noise ratio and the integration time. To achieve this evaluation in a meaningful way a uniform source sheet with a small hole at its centre is considered (Fig. 5). The image contours will not have a discontinuity corresponding to the hole edge but will vary gradually to a minimal value at the centre of the hole. Detection of the hole therefore depends on the fractional image density difference between the outside and the interior of the hole (Fig. 5).

The other significant difference between the proposed system and the collimator system is that data processing is an integral part of the optical system. In the Compton system it is possible to effectively improve the optical properties of the detector by

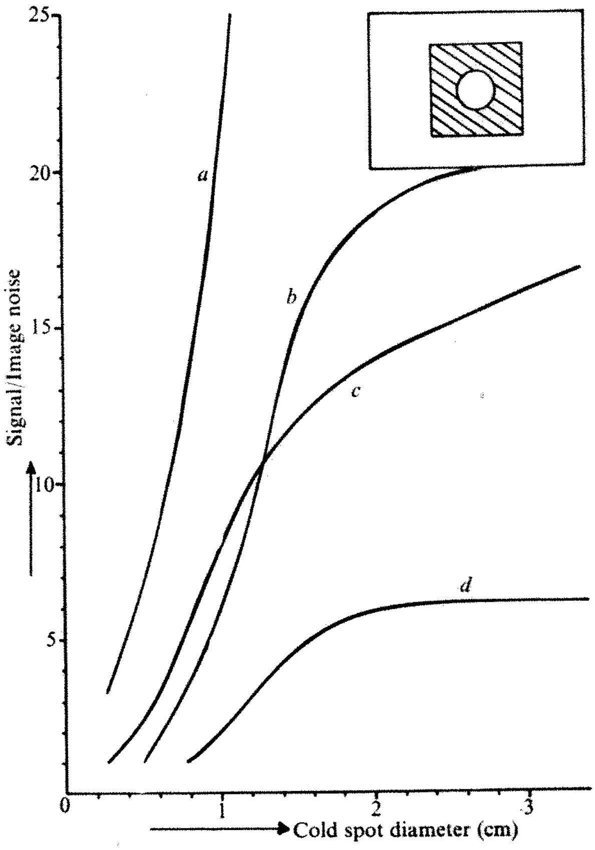

Fig. 5 Signal to image noise ratio against the cold spot diameter. *a*, Compton system, 10^6 ellipses (10 s); *b*, collimated system, 10^6 counts (1,000 s); *c*, Compton system, 10^5 ellipses (1 s); *d*, collimated system, 10^5 counts (100 s). Imaging times refer to a 400 Ci source; average source activity is one third of peak activity; there was no image processing. Inset: radioactive source sheet with a hole at its centre.

operating on the incoming data during the formation of the image. In the collimator systems, data processing is normally only applied to the completed image.

If it were necessary to draw each individual ellipse the display problem would be immense. Using statistical estimation, however, it seems possible to produce best estimates of the intersection point without having to display each ellipse. The extra computation involved is extremely small.

A number of practical problems arise which have led to further studies. These include the determination of the sequence of interactions, the removal of spurious data by time coincidence methods, amplification of a large number of low intensity pulses, and detector fabrication. Research carried out so far indicates that none of these problems have any serious implication to the basic concept.

Carbon isotope fractionations in natural gases

THE origin of gaseous hydrocarbons has been considerably illuminated by isotope analyses of natural gases. We shall try here to establish a model, explaining the isotopic fractionations of methane as a function of the thermocatalytic development of the corresponding source material. Because the origin of gaseous hydrocarbons is closely related to the formation of crude oil on one hand and the thermocatalytic state of the organic source material on the other, isotopic investigations can be of great interest in exploration for hydrocarbons.

The results of isotope analyses of natural gases from Japan[1], Taiwan[2], Italy[3] and the DDR[4] are compared with isotope measurements of gases from the Federal Republic of Germany[5]

The German gases were taken from different geological formations and wells of the north-western German oil and gas province. The methane (C_1) of the sampled gases was separated from the remaining gas components by liquid oxygen separation[5], combusted to carbon dioxide and its carbon isotope composition determined in a mass spectrometer (Atlas-Varian M 86). The isotope ratios are given in the usual δ notation:

$$\delta^{13}C_1 = [(^{13}C/^{12}C)_{\text{sample}} - (^{13}C/^{12}C)_{\text{standard}}]/(^{13}C/^{12}C)_{\text{standard}} \times 1000(‰)$$

The reference gas (standard) is the PDB-standard, which is representative of the isotopic composition of a marine carbonate. The reproducibility of the δ values is ± 0.3‰. The $\delta^{13}C_1$ values of dry natural gases are shown in Fig. 1 and plotted against the ratio of methane (C_1) over all saturated gaseous hydrocarbons (ΣC_n). Gases associated with oil or with high carbon dioxide content are omitted because of possible isotope exchange fractionations.

Biogenic alteration of the organic matter is predominant during the first few feet of sedimentary burial. Bacterial action on the organic material results in methane enriched in the light ^{12}C isotope[6]. Further sedimentation brings the organic material to a greater depth and thus into higher temperature zones. Chemical processes such as hydrolysis, cracking and hydrogen disproportion become more and more important. Reaction rates double for every 10° C rise in temperature. Isotopic fractionation occurs as a result of the different binding energies of the various isotopic molecules: ^{12}C–^{12}C bonds are the first bonds to be destroyed by thermal stress[7]. The methane emerging from the first stages of thermocatalytic alteration of source material is therefore rich in the light isotopes. Consequently the 'young' gases from Japan and Southern Italy (Fig. 1) are characterised by large amounts of methane ($C_1/\Sigma C_n > 0.99$) with low concentrations of ^{13}C ($\delta^{13}C_1 < -60‰$). With deeper burial, as the thermal stress on carbon complexes increases, more ^{13}C–^{12}C bonds are broken and the gas becomes isotopically heavier. Increasing thermocatalysis also causes the ratio of methane to all saturated gaseous hydrocarbons ($C_1/\Sigma C_n$) to change in favour of the higher hydrocarbons[8]. The extent of thermocatalytic change is dependent on temperature, that is, on the depth of the source bed formation, the time of maximum temperature influence, and the time when the reservoir rock became a closed system. Therefore, the degree of thermocatalytic alteration of organic material is sometimes linked to the geological age of the source bed formation and, subsequently, to the age or depth of the reservoir bed of the natural gases. This trend is shown by the data of the Quaternary Japanese, the Tertiary Southern Italian and the Permian or Triassic natural gases from the Thuringian Basin (Fig. 1), in which the source bed material is of predominantly marine origin. A turning point in the development of marine organic material is represented by the data on Permian natural gases from the Thuringian Basin, ($C_1/\Sigma C_n \approx 0.8$; $\delta^{13}C_1 \approx -42‰$). As the organic source material is further altered, the hydrocarbons released

are increasingly cracked, and the methane content of the gas and the $^{13}C/^{12}C$ ratio of the methane increases. This stage is represented by the Taiwan data. The thermocatalytic development of this source material has been accelerated by magmatic events during the Tertiary. In the final stage, all higher hydrocarbons are converted into methane by cracking, enriched in the heavy isotope. This final stage of thermocatalysis is shown by the analytical data of deep dry Ordovician and Silurian gases from West Texas (W. Stahl and B. D. Carey, in preparation).

On the other hand, the methane content of the gases produced during the formation of coal, for example the Carboniferous, Permian and Triassic natural gases of the Federal Republic of Germany, is also considerably enriched in ^{13}C. These gases, formed when predominantly terrestrial organic material is converted to coal, show properties comparable with gases from the cracking stage of marine source material: the $\delta^{13}C_1$ values change with increasing thermal stress in favour of the ^{13}C isotope, methane content increases, and the amount of higher hydrocarbons decreases with increasing degrees of conversion to coal.

The observations discussed here are summarised in Fig. 2, where an economically important application of the model is demonstrated, the distinction of pure methane gases of different origin. The origin of methane gases characterised by low δ values, that is enriched in ^{12}C, can be traced back to young organic material, which was only affected by relatively low temperatures. High ^{13}C concentrations in methane show that the gas originated during coal formation processes or during the thermal destruction of marine organic matter or liquid hydrocarbons under relatively high temperatures. In this case, the probability of finding crude oil will be extremely small.

I thank Dr B. D. Carey, Tenneco Oil Company, Houston, Professor H. Boigk and Dr B. Hückel, Bundesanstalt für Bodenforschung, Hannover, for discussions.

Evidence on the locomotor pattern of *Homo* from early Pleistocene of Kenya

Here I present the results of the application of two multivariate statistical techniques, a linear function and a distance statistic, in the analysis of a hominid talus bone. They provide additional objective evidence that this talus, found at East Rudolf, North Kenya, in 1971, should be included in the genus *Homo*. They also indicate that the morphology of the bone is compatible with early *Homo* having a lower limb functioning like that of modern man.

The specimen, KNM-ER813 (ref. 1), is a well preserved right talus; details of its morphology have been described and illustrated elsewhere[2]. It was recovered from beds between tuffaceous horizons that have been correlated with tuffs dated at 2.61±0.26 and 1.57±0.00 million yr (Myr) by argon isotope techniques[3].

Comparative data which have been used as a reference framework are listed in Table 2 and details of the groups have been given in previous reports[4,5]. Three angular and five linear measurements were made on 318 adult tali. These measurements relate to the size and disposition of the articular surfaces, and were selected both for their reproducibility and for their biomechanical significance in locomotion. The five linear measurements were made up into four indices to reduce the effects of overall size disparity in bones that are of the same shape. The values of the variables for the fossil are given in Table 1 (see ref. 4 for further details of measurements).

Canonical analysis of these data, using the BMD 07M program[6], resulted in five significant canonical variates. Variate I, containing 76% of the total variability, isolated the modern human tali; variate II separated the knuckle-walking category; the two subsequent variates separated the arboreal forms, from the rest (III), and from each other (IV); variate V was nondiscriminatory.

The canonical coefficients of these first four variates have been applied to the fossil data, a procedure that is quite proper[7]. In all the variates, the fossil is aligned with the modern human tali and in the first canonical axis (which by definition effects the greatest measure of separation) the fossil is especially close to man (Fig. 1).

Table 1 Data for the fossil talus

Variables	Horizontal angle	Dip angle	Torsion angle	Neck length index	Head projection index	Trochlear shape index	Fibular facet projection index
KNM-ER813	14	25.5	48	130	40	91	222

The Mahalanobis D^2 distances of the fossil from the comparative groups are given in Table 2. The distances between the fossil and all three groups of modern human tali are small, so small in the cases of the Bushmen and the Modern groups that the distances are not statistically significant. These D^2 results indicate that the behaviour of the fossil in the canonical variates, in particular in variate I, are a true reflection of its affinities (Oxnard has recently pointed out that this may not be the case where large and significant D^2 distances are involved[8]).

Although the multivariate analysis results are expressed in fewer dimensions than there are measurements, they confirm the close morphological similarity that exists between the fossil and modern human tali. Their relevance for its classification are that they strengthen preliminary assessments which placed this fossil talus in the genus *Homo*[1,2]. There is evidence from other fossils that the *Homo* lineage is present at East Rudolf in deposits both older and younger than those in which this fossil was found[1,9]. It cannot be certain to which grade or chronospecies of *Homo* this talus belongs for no talus has been found associated with fossils characteristic of the 'erectus' grade of the *Homo* lineage. Two femur shafts, however, KNM-ER737 and 803, that are broadly contemporaneous with the talus, show features characteristic of the *Homo erectus* femurs from Choukoutient and Olduvai Gorge[10].

Considering the locomotor implications of these results, although the modern human locomotor pattern seems to be associated with a particular talar morphology, one would be guilty of the *post-hoc* fallacy in assuming that a similar talus was necessarily part of the same sort of hind limb functional complex. Nevertheless, with that caveat, the functional implications of the canonical analysis results, combined with the close morphological affinity of the fossil talus with the modern human bones, make it probable that the locomotor pattern of this early hominid was like that of modern man. More comparative and functional data from other bones in the lower limb are needed to confirm this hypothesis.

One of the objects of accumulating comparative material has been that the groups could be used as a framework to compare fossil bones. Similar fossils would be associated on the canonical variates and their D^2 distances from the comparative groups should be similar. It is of particular interest, therefore, that this East Rudolf talus and a talus of a similar time period, OH8 from Olduvai Gorge, Tanzania, behave differently in the analysis[4]. The suggested implications of these differences for the classification and phylogenetic interpretation of the Olduvai specimen will be presented elsewhere.

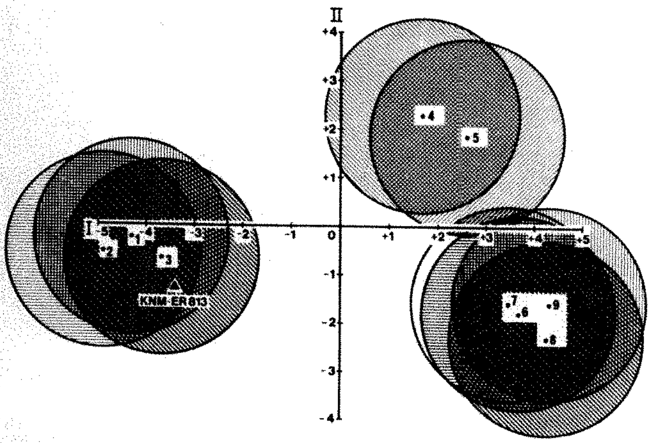

Fig. 1 Plot of canonical variates I and II. Circles are drawn with a radius of 2 s.d. The group numbers are identified in Table 2.

Coal smoke and mortality of the elderly

MORTALITY from falls in old people is so closely related to mortality from fractures of long bones, particularly of the proximal femur, that it seems to be related to bone fragility[1–3]. Although the mortality of women aged 75 yr and over is more than 50% higher than that of old men, there has been a close relationship between male and female annual mortalities in both Britain and the United States. This suggests that some common contemporary factors affected the mortality, and possibly the bone fragility, of each sex, even though their total experiences of mortality were substantially different. The evidence presented here suggests that coal smoke is one such factor.

A striking feature of mortality from falls of the elderly in Britain has been the recession in mortality over the period of wartime and post-war austerity from 1940 to 1950, subsequently rising to be followed later by a steady fall since 1958–59. This pattern, which appears in the mortalities of both men and women aged 75 yr and more[1,2], resembles that shown by annual estimates of atmospheric pollution by domestic coal smoke. This is illustrated in Fig. 1.

The estimates of annual emission of smoke from house coal shown in Fig. 1 were obtained, together with estimates of railway smoke from steam locomotives and industrial smoke, from estimates given by the Warren Spring Laboratory[4] for the years 1952–65 based on data of coal consumption. For years before and after that period the factors used to make these estimates (weight of smoke = 3.5% of domestic coal, 2% railway coal, 0.5–1.2% industrial coal) were applied to data of annual coal consumption compiled for those years[5]. The relationships of mortality to estimated annual emission of coal smoke are shown in Table 1. Mortalities are related to domestic smoke pollution for both men and women but only for bronchitis in women to industrial smoke, the highest correlations being between domestic smoke and falls, both in men ($r = 0.73$) and in women ($r = 0.82$).

The immediate cause of death of an elderly person immobilised by a fractured femur is usually a lung infection. The mortality of middle-aged people up to the age of 75 yr in County Boroughs has been related, *inter alia*, to estimates of domestic smoke pollution in the different boroughs, a principal cause of the relationship being mortality from bronchitis[6,7].

The mortality from bronchitis of women aged over 75 yr is shown in Table 1 to be highly correlated with mortality from falls ($r = 0.70$) and with domestic smoke ($r = 0.78$), bronchitis in men has lower correlation coefficients both with falls ($r = 0.51$) and smoke ($r = 0.37$). Mortality of men from bronchitis is higher than that of women, and additional factors, particularly tobacco, affect their mortality from bronchitis. The marked recession in mortality from falls in 1940–50 followed by post-war peaks in 1956 and 1958–59 did not occur in mortality from bronchitis, but the annual fluctuations of mortality from bronchitis were reduplicated at a lower amplitude by the mortality from falls. There was an increased risk of death following a fall in bad years for bronchitis.

Table 1 Correlations and multiple regressions of death rates from falls with death rates from bronchitis and domestic smoke pollution

Coefficients of linear correlation (r)		Bronchitis mortality i	Domestic smoke ii	Industrial smoke iii
		r	r	r
Bronchitis mortality	male		0.37*	0.17‡
	female		0.78†	0.63†
Falls mortality	male	0.51*	0.73†	0.12‡
	female	0.70†	0.82†	0.17‡
Multiple regression				
Partial regression coefficients (b)		b_{i}	b_{ii}	
Falls mortality	male	0.046*	0.479†	
	female	0.024‡	0.721†	

For the multiple regression the multiple correlation coefficient, R was 0.78† for men and 0.83† for women.

Industrial smoke includes railway smoke.

* $P<0.05$

† $P<0.001$

‡ Not significant

Analysis by multiple regression with mortality from falls as the dependent variable and two independent variables—domestic smoke pollution and mortality due to bronchitis—gives highly significant regression coefficients for smoke pollution both in men and women ($P<0.001$), the regression coefficient for bronchitis for women is not statistically significant ($0.25<P<0.4$) but is probably significant for men ($P = 0.02$) at a much lower significance than for smoke pollution. Mortality from falls (and by inference from fractures of the long bones) seems, therefore, to be related to domestic smoke pollution independently of the relationship to mortality from bronchitis.

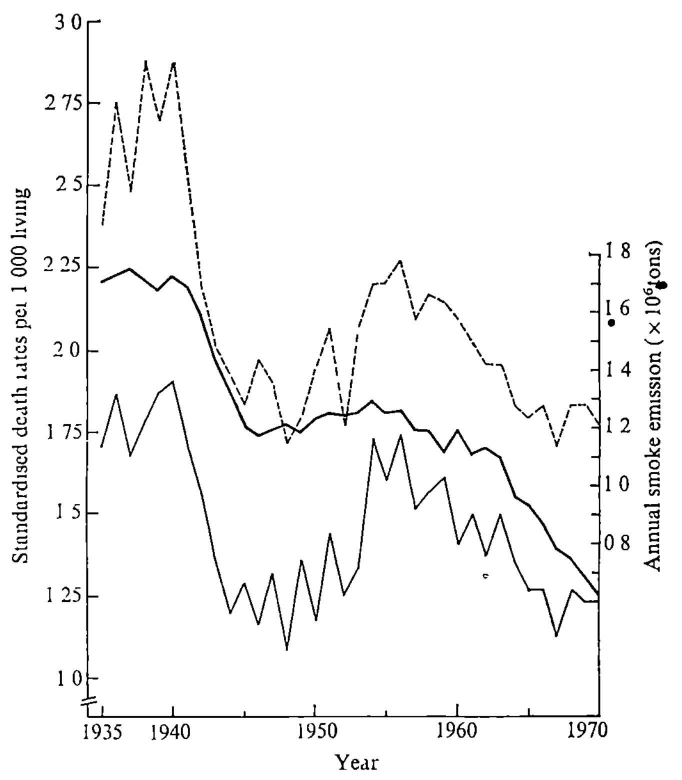

Fig. 1 Death rates at age 75 yr and over for accidental falls (E880-7 eighth revision International Classification of Diseases) compared with estimated annual emission of domestic coal smoke. Death rates are directly standardised for age and sex on the total male and female 1961 population at age. —— Male death rates, – – – female death rates, —— smoke emission.

The steep rise in femoral fractures with advancing age in Britain may be attributable to an absolute or relative deficiency of vitamin D (refs 8 and 9). In Detroit (latitude 42°N) serum antirachitic activity, as well as being related to season and sunshine, was significantly less in symptomatic osteoporotic subjects than in the skeletally normal[10]. There is increasing evidence of the importance of endogenous synthesis of vitamin D by ultraviolet irradiation of 7-dehydrocholesterol in the skin[11], even in the higher latitude of London (52°N) where there are seasonal changes in plasma levels of 25-hydroxycholecalciferol[12]. When smoke pollution was at its height in 1937–39, it was estimated that in Leicester (latitude 53°N) at least 30% more ultraviolet daylight would have reached the centre of the city in winter if all the smoke in the atmosphere had been eliminated, and occasionally the loss was more than half[13]. The effect of smoke on mortality from falls and fractures may therefore have been due to reduced endogenous synthesis by ultraviolet light.

These relationships between mortality and environmental change have implications beyond the restricted area of geriatric mortality. Because they are a dying generation at the end of the human life span, factors affecting the inevitably high mortality and causes of death of people over 75 yr of age are fewer and simpler than the much more complex influences affecting the lower mortalities of middle age. Though they will succumb to illnesses and infections which would be trivial and easily treated in a younger person, they will have survived or no longer be subjected to many of the stresses and influences competing for life or death affecting mortality and morbidity in middle age They may therefore show relationships of mortality to single factors in environmental change which are masked by complex multifactorial influences at younger ages The simpler relationship of mortality from bronchitis in women to both domestic and industrial smoke is particularly notable

Genetics of cannibalism in a viviparous fish and its relationship to population density

THE success of viviparous species is a result of their capacity to produce small numbers of advanced offspring with high survivorship potential Cannibalism, which would appear to be antithetical to this adaptation, is widespread among viviparous fishes[1–3] I have examined the genetics of cannibalism and the significance of its density-dependent mechanism in teleosts of the genus *Poeciliopsis* A five-membered unisexual–bisexual complex has evolved in this genus through hybridisation of a cannibalistic species, *Poeciliopsis monacha*, with the noncannibalistic species, *P lucida* Hybridisation of these two species formed *P monacha-lucida*[4], a diploid unisexual, backcrosses of this diploid form with each of its progenitors resulted in the evolution of two triploid unisexuals *P monacha*-2 *lucida* and *P* 2 *monacha-lucida*[5] All these rely on males of the bisexual species for fertilisation

The unisexual–bisexual complex represents an array of morphological and biochemical characters[5,6] that demonstrate the genetic intermediacy of unisexuals according to genome dosage of parental forms I have investigated whether the degree of cannibalism also follows genome dosage and whether adult and/or young densities influence the expression of this trait

Live and preserved stocks of *Poeciliopsis* were obtained from natural populations in the Rio del Fuerte of Sonora and Sinaloa, Mexico Mature virgin females were maintained in 75 7-l aquaria with sparse amounts of *Najas* and *Vallisneria*, many snails, and fed twice daily with commercial dry food supplemented with live *Daphnia* Females were established at densities of five, ten, fifteen and twenty, plus a control with no females

Young fish obtained from stock females were screened for developmental abnormalities on the day of birth, and then introduced at densities of five, ten, fifteen and twenty into the experimental aquaria containing the mature females Most young were of the same brood, however, samples of fifteen and twenty young were formed occasionally by combining broods of different females Young remained with the predators for 24 h, after which survivors were removed and counted Preliminary experimentation demonstrated that young would not be cannibalised after 24 h Mortality in fifty controls each of 24 h duration was zero

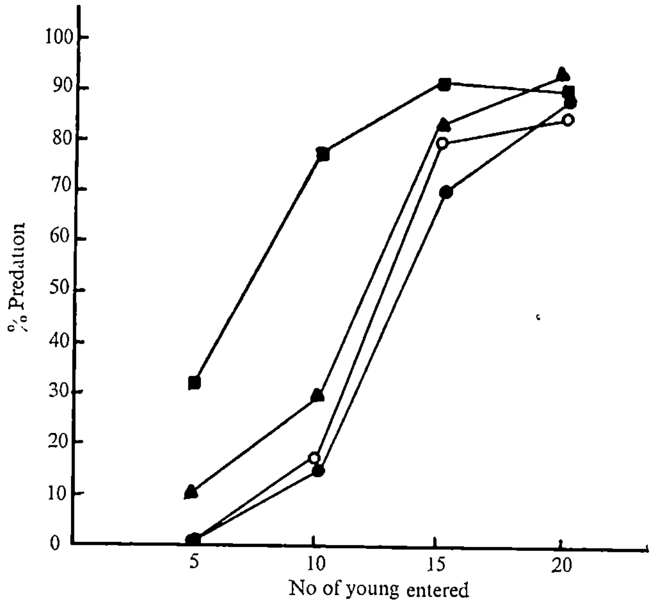

Fig. 1 Relationship of predator and prey densities to predation rates Females of *Poeciliopsis monacha-lucida*, *P* 2 *monacha-lucida* and *P monacha* served as predators of newborn young of all five species of *Poeciliopsis* These females were used because of large sample sizes and their consistent cannibalistic behaviour Densities of females were ●, five, ○, ten, ■, fifteen, ▲, twenty

Among the five unisexual–bisexual *Poeciliopsis, P lucida* proved to be noncannibalistic whereas *P monacha* consumed young in nearly all trials (Table 1) *P monacha-lucida*, the genetically intermediate hybrid, ate young in about three out of four trials The two triploids cannibalised at rates similar to that of the bisexual species to which they are genetically more similar *P monacha*-2 *lucida* ate young nearly as infrequently as *P lucida*, *P* 2 *monacha-lucida* nearly as avidly as *P monacha* The degree of cannibalism, like morphological expression, thus comprises an array directly related to genome dosage This is the first time the predatory phenomenon has been demonstrated to be heritable Stomach analyses of wild females confirm that certain species of *Poeciliopsis* eat young and that cannibalism is not a laboratory artefact

Cannibalism, believed to be polygenically controlled, is a complex behavioural phenomenon related to feeding habits The practice of cannibalism by *P monacha* and not by *P lucida* is probably related to their different morphology and ecology Dentitions, for example, differ *P monacha* has many tricuspid inner teeth whereas *P lucida* has few unicuspid inner teeth[5] *P monacha* is found in small headwater pools, *P lucida* in large and stable tributaries

Table 1 Frequencies for which any young were cannibalised by unisexual–bisexual *Poeciliopsis* in 136 trials

Species	Total no of trials	No of trials in which young were cannibalised	*F*
P lucida	19	0	0 0
P monacha-2 *lucida*	17	2	0 12
P monacha-lucida	54	40	0 74
P 2 *monacha-lucida*	25	22	0 88
P monacha	21	20	0 95

Table 2 Probability model comparing total survivorship potential of young produced by fishes with superfoetation and fishes without superfoetation in a catastrophic environment

Intervals of 10 d (total 100 d)	1	2	3	4	5	6	7	8	9	10
Young production with superfoetation	10	10	10	10	10	10	10	10	10	10
Young production without superfoetation	20	0	20	0	20	0	20	0	20	0

$$P_x = (n!/(x!(n-x)!))\,(p^{n-x}q^x)$$

$P_x = (\quad)$	× (No of young)	= (total young surviving)	$P_x = (\quad)$	× (No of young)	= (total young surviving)
$P_0 =$ 0 349	× 100	= 34 9	$P_0 =$ 0 59	× 100	= 59 0
$P_1 =$ 0 387	× 90	= 34 83	$P_1 =$ 0 328	× 80	= 26 24
$P_2 =$ 0 194	× 80	= 15 52	$P_2 =$ 0 073	× 60	= 4 38
$P_3 =$ 0 057	× 70	= 3 99	$P_3 =$ 0 008	× 40	= 0 32
$P_4 =$ 0 011	× 60	= 0 66	$P_4 =$ 0	× 20	= 0
$P_5 =$ 0 001	× 50	= 0 05	$P_5 =$ 0	× 0	= 0
P_6 10 = 0	× No of young	= 0			

$$\sum_{x=0}^{10} (P_x \times \text{No of young}) = \text{total No young surviving in 100 d} = 89\ 95 \qquad \sum_{x=0}^{5} (P_x \times \text{No of young}) = \text{total No young surviving in 100 d} = 89\ 94$$

The probability of a catastrophe occurring in any one day is 0 1 n is the total number of broods, x is the number of broods lost, p is the probability of a brood surviving (0 9) q is the probability of a brood lost (0 1), P_x is the probability of x number of broods being lost

Previous experimentation with *Poecilia reticulata* on cannibalism and fecundity under crowded conditions, supported the hypothesis for a water-borne substance that acted to reduce fecundity or increase the cannibalistic response[2] These conclusions do not seem to be applicable to *Poeciliopsis* populations Also, because cannibalism had previously been proposed as a density-dependent population regulatory mechanism in *Poeciliopsis*[7], I analysed my results with respect to variable numbers of predator and prey (Fig 1)

Intensity of predation is a function of the number of females present the more females are present, the more young will be consumed But more critically, intensity of predation is a function of the number of young introduced At densities of five or ten young, predation clustered at 0–25% regardless of female density With fifteen to twenty young, cannibalism increased to 70–90% For 128 trials, a two-way analysis of variance was used (F statistic highly significant ($P \leqslant 0\ 001$) for young density and ($P<0\ 001$) for female density)

The hypothetical value for the 'critical density' of between ten and fifteen young is consistent with laboratory observations of females preying on young When more than ten young were introduced to aquaria containing adult females, the young tended to school or aggregate near the surface, a characteristic of newborn *Poeciliopsis* Aggregates of young stimulate an attack response first by one female followed by mobbing behaviour from the others After the initial attack, young quickly disperse in the vegetation or remain immobile, in the absence of schools, the searching response by the females gradually subsides over the next few hours

Aggregates of ten young or fewer do not stimulate a predatory reaction, however, they are eaten at random when encountered by a female, thus explaining the relationship of the number of females to the rate of cannibalism Cannibalism is less related to hunger than to predator–prey density phenomena Females starved for 2–4 d ate no more young than did well-fed females Furthermore, females encountering large densities of young remain unsatiated until the brood is eradicated Discrimination of young is not involved In a mixed environment, the probability of an individual eating its own young is low since cannibalism is suppressed until parturition is completed

The adaptive value of cannibalism is unclear Experimentation indicates advantage for lower densities of young Newborn young emerging in smaller groups should have higher survivorship values than young born in larger groups

All species of *Poeciliopsis* exhibit superfoetation, the simultaneous development within the ovary of more than one embryonic stage *P lucida, P monacha* and associated unisexuals produce half as many young twice as often as females of the same size of *Poecilia reticulata* which do not have superfoetation The former have mean brood intervals of 11 6 and 10 3 d respectively, whereas the latter has 21 1 d, *P monacha* and *P lucida* females of 30 to 35 mm total length have mean brood sizes of 11 8 and 11 0 young respectively compared with 30–35 mm *P reticulata* females with broods of 24 2 young[8] (unpublished work of myself and R J Schultz) The birth of small broods at frequent intervals may be an adaptation to a critical density for cannibalistic predation

Superfoetation is believed to have evolved independently in response to various selection pressures[9–10] Several theories on the adaptive value of superfoetation appear reasonable, but they break down under close scrutiny Superfoetation may allow females to utilise space devoted to reproduction more efficiently by partitioning the young into different developmental states, thereby increasing total fecundity, however, fishes without superfoetation have attained brood sizes of 180 and 315 young[11] far exceeding twice the maximum brood size of 80 young of *P monacha* females of comparable sizes (unpublished work of myself and R J Schultz)

Superfoetation may also be beneficial to fishes inhabiting unstable environments such as those of *Poeciliopsis* which are characterised by floods, droughts and extreme temperatures, all with the potential of eradicating an entire brood of young By scattering broods of smaller numbers, young of fishes with superfoetation may exhibit higher survivorship potential But, a simple probability model contrasts the reproductive potential of fishes with superfoetation with that of fishes without superfoetation in a catastrophic environment where catastrophies are random and unpredictable (Table 2) In this design, both types of fish have equal probability of producing the same numbers of young in a set interval superfoetation yields no advantage

The adaptive value of superfoetation is unclear In spite of the function of cannibalism in the regulation of population size, the adaptiveness is also ambiguous However, superfoetation and cannibalism are correlated in the producton and survivorship of small broods in *Poeciliopsis* Cannibalism is probably uninvolved as a selective force in the evolution or maintenance of superfoetation, its persistence in viviparous fishes without superfoetation supports this But with the presence of the numerical predator–prey mechanism, cannibalism appears to be tolerated in the evolution of natural populations when superfoetation is present as a reproductive strategy

Depth perception in disparity gratings

OBSERVATION of sinusoidal spatial modulation of luminance has proved a valuable tool in the study of visual processing of luminance distributions on the retina Information on the limits of processing capability has been gained in such diverse fields as the optics of the eye[1], neurophysiology of the retina[2], movement[3,4] and orientation[5 6] sensitivity and cortical processing of spatial frequency[7 8] In the field of stereoscopic vision, Blakemore[9] and Fiorentini and Maffei[10] have found that when luminance gratings of slightly different spatial frequencies were presented to each eye, an apparently tilted grating was perceived even if one monocular grating was moving quickly relative to the other Furthermore, tilt is perceived from gratings of the same spatial frequency but differing in contrast by 50% or more These phenomena are not easy to explain on the basis of disparities at corresponding retinal points, but seem to require more global processing of the whole image

Julesz[11] has reached a similar conclusion on the basis of experiments with random-dot stereograms, which have the unique advantage of eliminating all correlated monocular cues to the stereoscopic figure (although the random dot texture acts as a monocular textural cue that the figure has a constant depth and works against the disparity information to some extent) Stereopsis can be obtained under several conditions which make it difficult to conceive of a local disparity process that could produce depth perception For example, alternation of two stereograms at 20 Hz does not destroy perception of a stereoscopic figure[12] Furthermore, in ambiguous stereograms the depth perceived depends on the global organisation of nearby dots[13]

It would be of value to combine the advantages of random-dot stereograms and of sinusoidal modulation techniques in the study of spatial limitations of cyclopean depth perception I have previously studied the effects of sinusoidal modulation of binocular disparity along a vertical axis on stereoscopic perception using line stereograms[14] The main stereoscopic processing limitations noted were a sharp high frequency limitation in sensitivity at about three cycles per degree (c p d) and a disparity scaling effect, in which the maximum disparity that could evoke a depth percept was directly proportional to the retinal angle subtended by each cycle of the vertical modulation Thus, the disparity limit is scaled in proportion to

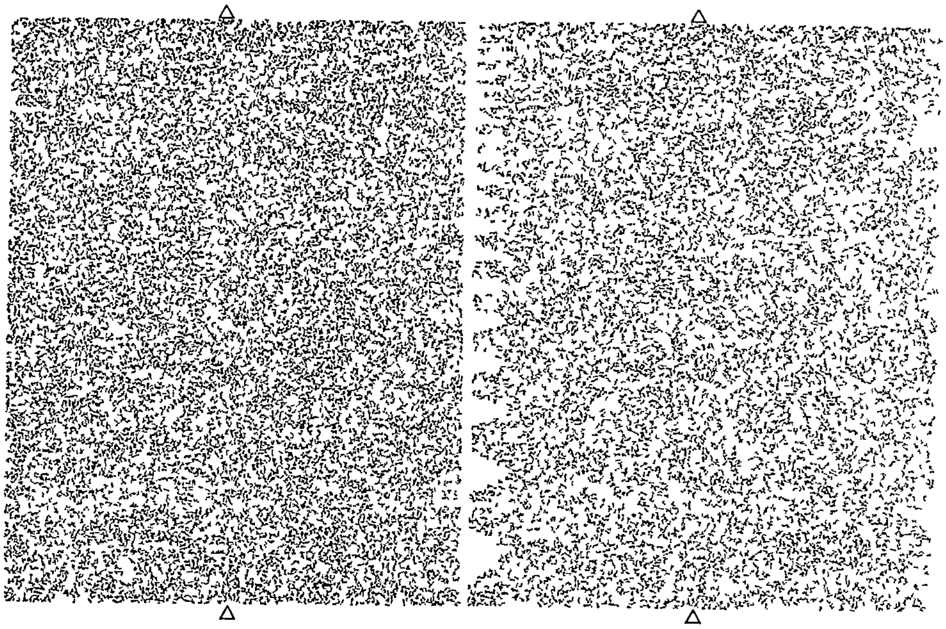

Fig 1 Demonstration stereograting This figure should be viewed by means of a simple stereoviewer requiring two white cards and a pair of spectacles With the figure at arm's length hold the cards at about 10 inches from the eyes Closing each eye in turn, align the cards so that each eye sees only one dot matrix It should now be possible with the aid of the fixation marks to register the two matrix images as a single square If this square remains blurred it may help to wear a pair of weakly hyperopic spectacles (in addition to any spectacles worn normally) Continued observation should reveal shallow horizontal ripples or cones increasing in spatial frequency upwards and becoming shallower towards the right Generation of random-dot disparity gratings was achieved by a Fortran program controlling the position of randomly selected points in a 10 × 8 inch matrix on a Calcomp plotter In measuring stereoscopic thresholds the problem that dot resolution is about 1 arc min visual angle, whereas disparity resolution requires down to 10 arc s, was solved by modifying the concept of a completely random matrix so that dot position was specified to one tenth of a dot width This gave minimum possible disparity shifts of about 13 arc s at the viewing distance of 200 cm Although horizontal changes in disparity theoretically introduce slight monocular cues to the disparity information, such cues are negligible in practice, since increasing the disparity range to ten times the largest used in this study did not introduce detectable monocular variation in dot density

size of the modulation cycles The experiments reported here show that the line stereogram results are replicated using random-dot stereogratings as stimuli and are probably general properties of the stereoscopic system

Generation of random-dot disparity gratings with a large range of disparity variation required a slight modification of Julesz's concept[11] (see Fig 1) A second technique enabled threshold sensitivity to be measured over a great range of amplitudes and frequencies of disparity modulation without generating a vast number of individual stereograms By analogy with the demonstration stimulus for luminance grating sensitivity[15] it is possible to produce continuous variations of both amplitude of disparity and spatial frequency as a frequency-swept, amplitude-decayed stereograting (Fig 1) The boundary between perception of the flat random-dot texture and the rippled surface of the stereograting is determined by the spatial frequency limits of disparity processing in the visual cortex

For demonstration, the monocular cues of the disparity ripple at the edges of the right hand matrix is present, but these were masked to straight edges during quantitative experiments The edge ripple in relation to the straight edge of the left-hand matrix indicates the precise disparity present down each edge of the figure Readers may verify that no changes in texture density correlated with the disparity variations are evident in Fig 1

To ensure that maximal stereoscopic information was available, free eye movements and long and active viewing times were encouraged The stereogratings were viewed through a Smith orthorater stereoscope Each subject was fully optically corrected, since individual dots were close to the limit of visual resolution The stimuli were Xerox copies of the Calcomp plot which had a luminance of 3 cd m^{-2} and were viewed at a distance of 200 cm Subjects were instructed to concentrate on each bar indicated in turn, and decide where in the matrix the bar disappeared into a flat surface They then directed the experimenter in marking the point on the matrix with a red mark invisible to the subject A complete set of spatial frequencies was measured twice

The results of the measurements of spatial frequency limitations of stereosensitivity for two subjects (Fig 2) are in general agreement with line stereosensitivity limits[14] The maximum frequency for which the stereograting can be resolved (Fig 2*a*) is about 4 c p d (compared with 3 c p d in line stereograms[14]), and is only slightly affected by a tenfold reduction in dot density (Note that at this frequency there are 7 dot widths or 70 dot positions per cycle) The slight discrepancy between the uppermost points in Fig 2*a* and the lowermost in Fig 2*b* is probably due to measurement error and may also be influenced by edge effects at the edge of the grating

Similar results may be obtained for previously published stereograms containing both vertical and horizontal gratings[16] The grating becomes invisible as viewing distance is increased so that the grating subtends about 4 c p d This is not due to lack of acuity for the monocular textural information, since in stereograms of the same texture at the same viewing distance a large stereoscopic figure such as a square is readily visible

High spatial frequency sensitivity may also be studied by removing high or low spatial frequency information from one matrix of a stereogram[16] Once again stereopsis is difficult (impossible for all five observers I tested) when there are no low spatial frequency cues to the stereoscopic figure, whereas lack of high spatial frequency information hardly affects stereoscopic perception

As with all measures of stereolimits there is a lower and an upper disparity for which perception of depth falls to threshold The former will be called stereoacuity and the latter the upper depth limit Stereoacuity falls in the region of the resolution of the Calcomp plotter, so it could not

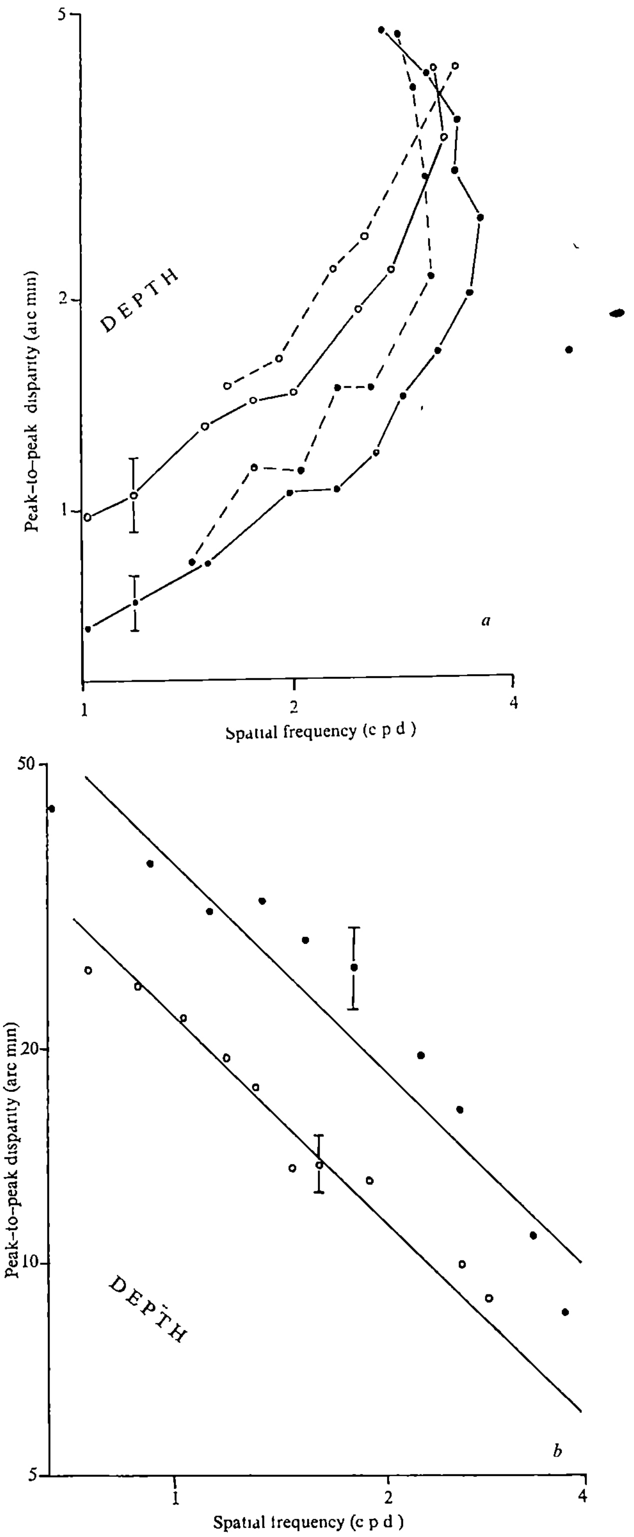

Fig. 2 Stereosensitivity for two subjects, J Z (○) and C W T (●) *a*, Region of maximum frequency, plotted in terms of peak-to-peak disparity variation versus spatial frequency of sinusoidal stereograting ——, 40% dot density, – – –, 4% dot density *b*, Region of maximum disparity in same coordinates, showing conformity to disparity scaling effect To obtain stereogratings with sufficiently low rate of change over a full range of spatial frequencies and amplitudes the gratings used were, *a*, 1–10 c p d , 0 5–5 arc min and *b*, 0 75–7 5 c p d , 5–50 arc min in spatial frequency and peak-to-peak amplitude range Both these stereogratings were produced with a dot density of 40% by area, but as a check on the effect of dot density *a* was also produced with dot density of 4% Variability of the data is shown as the average standard deviation of all pairs of readings (vertical bar above and below one point in Fig 2) In regions where the function is vertical the bar represents horizontal variability, since the direct viewing technique does not constrain the variability to one dimension

be measured by the present method For the upper depth limit, the maximum disparity (Fig 2*b*) decreases with increasing frequency, corresponding to a disparity scaling effect which conforms reasonably well with the equation (solid line in Fig 2*b*)

$$\eta = a/v$$

where η is peak-to-peak binocular disparity in arc degrees. v is spatial frequency in c p d and a is a scaling constant that has the values of approximately 0 3 for J Z and 0 6 for C W T These values may be compared with values of about 0 5 for C W T and 0 33 for another subject using line stereograms[14]

This disparity scaling equation describes a limit in rate of change of disparity across the retina This limit applies equally to global stereopsis from random-dot stereograms and qualitative stereopsis from line stereograms[18] The similarity of the scaling constant a for the two types of stimuli suggests that the disparity scaling limit is determined by the arrangement of disparity detectors in cyclopean space rather than by the difference in orientation between monocular line segments[17]

The homeothermic status of the neonatal dog

The capacity of a warm blooded animal to increase production and conservation of body heat when it is cooled and to dissipate heat when it is warmed largely determines that range of environmental temperatures within which a stable deep body temperature can be successfully achieved

In these respects the mature dog is an example of an efficient homeotherm, able to withstand the short-term effects of ambient temperatures as low as -100° C and as high as 42° C[1-3] In contrast, the neonatal dog demonstrates a relatively poor body temperature stability and when isolated in a cooling environment it tends to adopt the temperature of that environment[2,4] This has led to an assumption that the dog is poikilothermic for some time after birth[2,5] The concept of poikilothermy in this context may have been based on a too literal interpretation of the term homeothermy Body temperature stability is the product of a number of behavioural, physiological and metabolic processes[3,6] which characterise the homeothermic state and these clearly differentiate it from poikilothermy Appreciation of the differences is of some importance in the dog as the newborn of this species is often the subject of intensive medical care requiring segregation in an environment which makes minimal metabolic demands

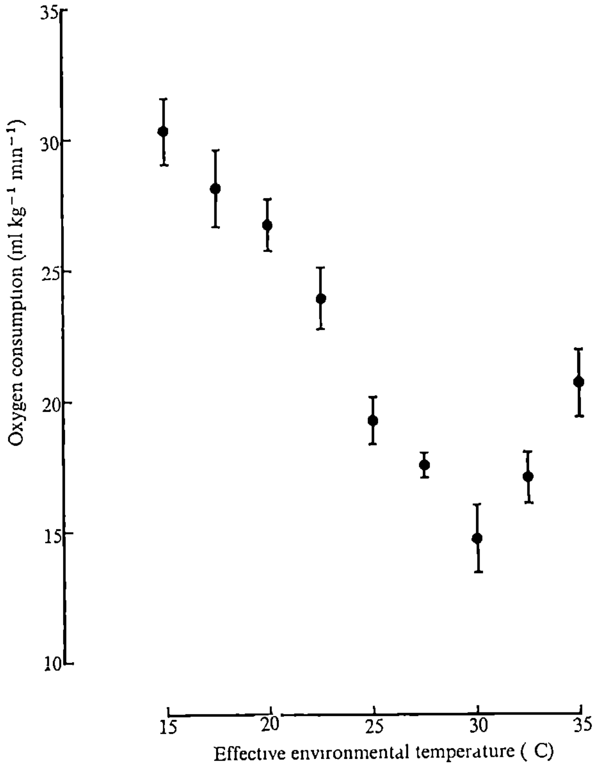

Fig. 1 Mean (± s e) oxygen consumption of groups of neonatal beagle dogs (3 d old) segregated at selected environmental temperatures for 30 min

Beagle puppies were used in this study They were housed with the bitch in insulated whelping boxes[7] in a constant ambient temperature of 28° C The core temperature of a post-prandial puppy 3 d old was recorded and it was then subjected to an interval of 30 min in an incubator at 30° C to establish equilibrium between core and surface temperatures before a period of experimental observation in an environmental chamber Nine temperatures, lying between 15° C and 35° C were used, and puppies were randomly allocated to not more than two of these temperatures on the day of observation

The environmental chamber was a Perspex cylinder surrounded by a water jacket which was incorporated into a closed air circuit, a modification of a design described earlier by other workers[8] A puppy in the chamber lay inside a plastic cylinder bearing multiple perforations to prevent bodily contact with the wall of the chamber The experimental environment was controlled in terms of air humidity (40–60%), air velocity (of the order of 1 5 cm s^{-1} surface speed) and temperature Internal wall and air temperatures were monitored by means of thermistors and the effective environmental temperature of the chamber was taken as their mean A period of 4 min was sufficient for equilibration of the apparatus after a puppy was introduced and thereafter oxygen consumption was recorded for a period of 30 min Carbon dioxide within the closed circuit was totally absorbed in a container of soda lime placed distal to the chamber in the direction of air flow Depletion of closed-circuit volume was restored by addition of fixed volume aliquots (20 ml) of pure oxygen from a float recorder which refilled automatically when empty Rate of oxygen consumption was computed as the regression coefficient of the equation relating the fixed volume of oxygen consumed to recorded times and was expressed as ml min^{-1} dry gas at s t p divided by body weight (kg) Core temperatures were recorded before and after each exposure by means of a thermistor probe inserted into the colon for a distance of approximately 6 cm Puppies were observed visually and their behaviour was recorded during periods of study Other beagle dogs 2 d old were subjected to periods of exposure in ambient temperatures between 8° and 35° C for intervals of up to 120 min Core temperatures were recorded in these instances, but not oxygen consumption.

Metabolic activity, expressed as oxygen consumption, of 3 d old puppies which were segregated in selected effective environmental temperatures for intervals of 30 min is illustrated in Fig 1 Mean oxygen consumption was minimal at an environmental temperature of 30° C Lower and higher temperatures resulted in an increase in oxygen consumption A significant difference was observed at 27 5° C ($P < 0\ 05$) and the mean rise of oxygen consumption over that range of cooling temperatures which was chosen was related to the degree of cooling stress At 15° C the mean oxygen consumption was twice that which was recorded at 30° C

Mean body weight of the group exposed to 30° C was 0 328 kg Mean oxygen consumption was 14 7 ml kg^{-1} min^{-1} Assuming that 1 ml of oxygen min^{-1} is equivalent to heat production of 7 2 kcalories/24 h (ref 8), and using a factor of 4 184 to convert kcalories to kJ (ref 6), the mean resting metabolic rate of these puppies in an environmental temperature of 30°C was 14 7 × 0 328 × 7 2 × 4 184 = 145 kJ per 24 h This compares favourably with a value of 127 kJ per 24 h which can be calculated for mammals of the same weight using the generally accepted level of 293 kJ kg$^{-3/4}$ per 24 h^{-1} for mean standard metabolic rate[6,9]

Characteristic behaviour was also observed (Table 1) At the environmental temperature at which oxygen consumption was minimal, puppies 3 d old relaxed at once and remained completely unconcerned with their surroundings At lower temperatures, a proportion of each group became alert, restless, hyperpnoeic and vocal The degree of persistence of these responses and the proportion of animals involved increased as environmental temperatures declined A similar syndrome was observed at temperatures of 32 5° C and higher Both syndromes ceased at once and the puppies resumed a state of relaxation and somnolence when they were returned to an incubator at a temperature of 30° C which appeared to be the preferred environment of puppies of this age

Core temperatures of puppies 3 d old were found on removal from the bitch to be 37 2 ± 0 4° C (mean ± s d $n = 90$) No significant differences were recorded after isolation and exposure to 30° C in an incubator or in the environmental chamber

Changes in the deep colonic temperature of these puppies are illustrated in Fig 2 If it is accepted that a mean change of colonic temperature of less than 0 5° C over a period of 30 min is indicative of thermoregulation, then puppies 3 d old were able to regulate in environmental temperatures between 20° - 30°C Exposure to temperatures outside this range resulted in deviations in body temperature which stimulated behaviour indicating that the onset of hypothermia or hyperthermia was not accepted passively (Table 1)

The influence of environmental temperatures on deep colonic temperature of puppies 2 d old after exposure for longer periods is shown in Table 2 Again, no significant changes in colonic temperatures were observed in the group exposed to 30° C in spite of a temperature differential between core and environment of 7° C A temperature differential of 12 5° C, that is an environmental temperature of 25° C, was also associated with a successful effort to regulate deep body temperatures When the initial core/environment differential was increased to 17° C degrees or more, however, puppies became hypothermic At 35°C, a core/environmental temperature differential of less than 2 5° C, hyperthermia was induced so rapidly and with such dramatic behavioural responses that observations were limited to intervals of 30 min In all instances in which deviations of deep colonic temperatures occurred, normal body temperatures were resumed after incubation at 30° C

Table 1 The behaviour of groups of beagle puppies (3 d old) segregated at selected environmental temperatures for 30 min

Effective environmental temperature (° C mean ± s e)	No of animals studied	Syndrome* Exhibited	%	95% confidence intervals[10]

*Alertness, restlessness, hyperpnoea and vocalisation Zero response indicated relaxation and somnolence

These data indicate that the neonatal dog has a well delineated thermally neutral zone (TNZ) within which at rest it demonstrates a metabolic rate typical of a small mammal At an ambient temperature which is within TNZ (30° C) it maintains a stable core temperature of the order of 37° C This is similar to the mean core temperature which we have recorded in neonatal dogs of this age taken straight from the litter These animals have a nychthemeral variation of less than 2° C Already at this early age the dog is tachymetabolic and cenothermic[11]

It also displays distinctive and measurable physiological temperature regulation especially to cooling, but a relatively narrow yet clearly distinguishable tolerated ambient temperature range This range lies approximately between 20° C and 30° C (Figs 1 and 2)

The behaviour of the neonatal dog at different ambient temperatures is especially revealing (Table 1) The animal appears to

be largely indifferent to its surroundings when it is within TNZ Within the range of tolerated ambient temperatures, in which by intrinsic means it is able to counteract the effects of thermal stress to sustain thermal balance, it demonstrates an awareness of its surroundings At ambient temperatures which mark the upper and lower limits of temperature survival and which result in progressive deviations from the preferred core temperature of the neonate, onset of hypothermia or hyperthermia is not accepted voluntarily

To consider fluctuations of core temperature in relation to ambient temperature alone and without reference to the presence of intrinsic thermoregulatory mechanisms and then go on to equate deviations of core temperature over selected ranges of ambient temperatures with a situation akin to poikilothermy may be misleading We would cite the data in Table 2 At an effective environment temperature of 35° C, far from adopting this temperature as its core temperature, the core temperature of the neonatal dog rises dramatically It is the presence rather than the efficacy of physiological temperature regulation which could well be the final arbiter when taxonomical difficulties are encountered

Temperature regulation of the neonatal dog is admittedly very much more restricted compared with the adult, but this may be regarded as simply an expression of an immature phase in the development of what later becomes a highly efficient form of body temperature homeostasis in this species We submit that our data go some way towards fulfilling the essential criteria by which one should judge a homeotherm and we conclude that the neonatal dog is an immature homeotherm, thus rejecting the hypothesis that it could be described as poikilothermic at this age

Cyclic AMP levels in *Phycomyces* during a response to light

One of the many metabolic functions attributed to adenosine 3′ 5′-cyclic monophosphate (cyclic AMP) is that of a mediator in the responses of living organisms to light stimulation It has been associated with dopaminergic synaptic activities and also with the primary visual process in the retina In the rod outer segments of the frog, *Rana pipiens*, cyclic AMP concentrations are diminished by illumination Regulation is through the cyclic nucleotide phosphodiesterase[1] In addition, an adenyl cyclase has been isolated from retina which is activated by the catecholamine dopamine, dopamine is thought to be an important neurotransmitter in the retina[2] The exact relationship between the initial transduction of the light signal and the attenuation in the levels of cyclic AMP is unknown One reason for this is the complexity of the tissue and the difficulty of isolating clean fractions I describe here a simpler system in which levels of cyclic AMP decrease in response to light stimulation much as in retina and where all the transduction occurs within a single cell

The sporangiophore of the fungus *Phycomyces blakesleeanus* is a giant single cell—several cm long and 100 μm in diameter—which responds in minutes to light, gravity, touch and the proximity of objects, the last being termed its autochemotropism (formerly avoidance) In a mature sporangiophore (stage IVb), the sensitive area is identical to the growing zone, a region 3 mm long, just below the apical sporangium, where essentially all elongation occurs[3] In the case of the response to light, the nature of the behaviour has been worked out in detail using an automatic tracking system[4], and several mutants have been isolated[5] Figure 1 illustrates an example of a growth response to an increase in light intensity The response is transient with a latency of about 3 5 min, maximal at 4–5 min and essentially complete after 12 min The noise has been shown to be endogenous and to be associated with growth regulation after the reception of the light signal[4] However, in spite of some initial efforts[6], no chemical or morphological events have been shown to accompany or precede the observed acceleration of growth I have investigated the levels of cyclic AMP in *Phycomyces* sporangiophores and found a sharp decrease well before the observed growth response

P blakesleeanus, NRRL1555, was grown on 4% potato dextrose agar supplemented with 0 1% yeast extract Synchrony of sporangiophore development was achieved by a transfer from dark to light The mature sporangiophores (3 5±0 2 cm) were dark adapted for 40 min At time zero they were exposed to 3 μW cm^{-2} continuous fluorescent light At intervals 1 g of sporangiophores was plucked, quick frozen in liquid nitrogen and ground with a pestle and mortar The fine powder was rehomogenised in perchloric acid and the supernatant liquid, after precipitation of proteins and KClO$_4$, was subjected to anionic exchange chromatography A tracer of approximately 8,000 c p m ^{3}H-cyclic AMP was added at the homogenisation step to aid observation of the elution profile and assessment of final recovery Recoveries varied from 75 to 95% However, only the middle 40% of the cyclic AMP peak eluted from the column was pooled, concentrated and assayed Final results were corrected for recovery and subfractionation I used the assay of Brown *et al*[7] which is a modification of the competitive binding protein assay of Gilman[8] The amounts of cyclic AMP found in dark adapted sporangiophores varied from 0 1 to 0 3 nmol g^{-1} of wet weight Figure 2 illustrates the normalised

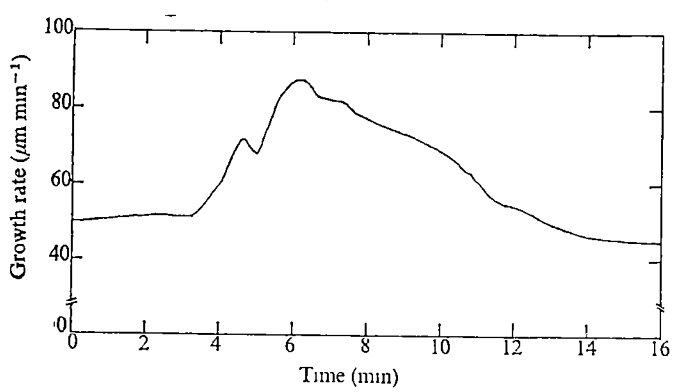

Fig 1 A typical growth response of *Phycomyces blakesleeanus* to an increase of light intensity at 24° C Conditions are comparable with those used to assay cyclic AMP The adapting light intensity was in the normal range, less than about 20 μW cm^{-2} and the final light intensity was sufficient to saturate the response system The step-up was imposed at time zero The latency was 3 5 min

results of assays for cyclic AMP during a response to continuous light

Cyclic AMP levels decreased precipitously to about 50% of the initial dark value within 1 min of light stimulation, well before the appearance of a growth response Indeed the level had returned to approximately the preillumination value at about the time that growth was first observed This is the first direct *in vivo* demonstration of a change in cyclic AMP level in a responsive system after light stimulation The sharp decrease in cyclic AMP suggests that the light receptor for *Phycomyces* is a nucleotide cyclase or possibly a cyclic mononucleotide phosphodiesterase, or may be closely associated with one of these enzymes such that light inhibits adenyl cyclase or activates phosphodiesterase Thus the primary transduction event may be the attenuation of cyclic AMP concentration Goridis and Virmaux[9] hypothesised that attenuation of phosphodiesterase is the general mechanism for the function of all sensory receptors

Because the slight decrease in cyclic AMP during the transient growth response was unexpected, the investigation was extended beyond the response (Fig 2) I found that levels of cyclic AMP had stabilised after the response, the levels in continuous light were perhaps slightly lower in these experiments than during continuous darkness

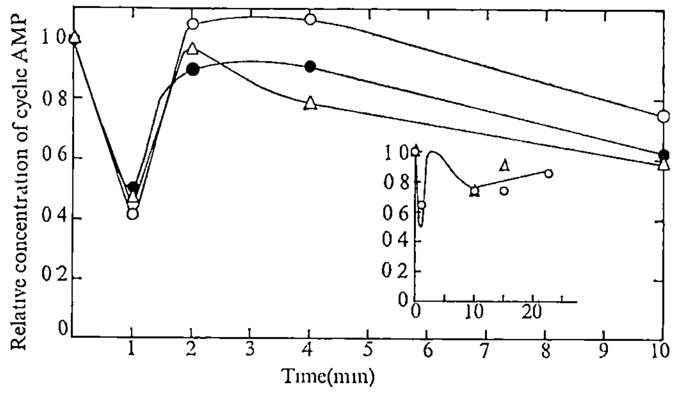

Fig 2 The normalised level of cyclic AMP in stage IVb sporangiophore as a function of the time after a light step-up at time zero The curves refer to three separate runs, each point being the mean average of five to eight determinations The absolute amounts of cyclic AMP initially present were ○, 150, ●, 302, △, 113 pmol g^{-1} wet weight Standard deviations of the mean ranged from 10 to 15% Temperature was 24° C The amount of protein in these sporangiophores was 5 0 mg g^{-1} wet weight as measured by the method of Lowry Details of the procedure are given in the text The inset shows levels of cyclic AMP in stage IVb sporangiophores extended to 25 min after the increase Other details are as in the rest of the figure The absolute amounts of cyclic AMP initially present were ○, 273 and △, 282 pmol g^{-1} wet weight

Because levels of possible interfering substances have not been investigated thoroughly in fungal material, I was careful to eliminate factors other than cyclic AMP that might affect my measurements The validity of the reported estimates is supported by (*a*) the careful ion-exchange column isolation, (*b*) the fact that when isolate was subjected to prolonged treatment with rat brain phosphodiesterase[10], boiled and reassayed, no cyclic AMP was found, while in a parallel experiment without this treatment the usual amount was found, and (*c*) several dilutions of cyclic AMP isolate yielded identical initial concentrations

Preliminary investigations indicate a very high adenyl cyclase activity consistent with high levels of product Cytoplasm from *Phycomyces* sporangiophores grown and assayed in continuous light has a V_{max} of 1 3 nmol of cyclic AMP produced per min per mg of protein and a high affinity for ATP (K_m=0 5 mM) as assayed by a slight modification of the method of Bar and Hechter[11]

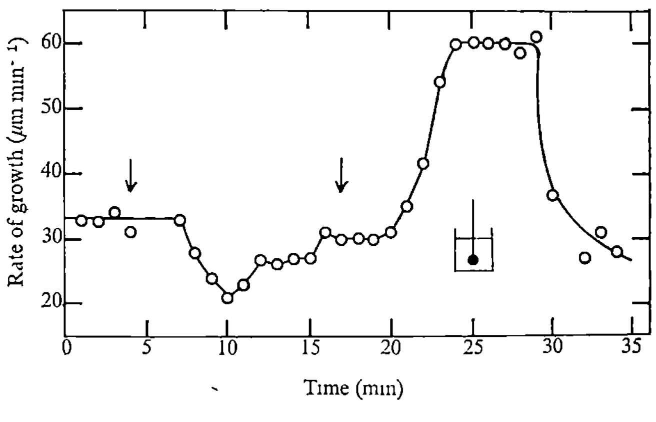

Fig 3 The response to the addition of dibutryl cyclic AMP (indicated by left hand arrow) to a growing sporangiophore The sporangiophore was initially suspended in fluorocarbon so that the growing zone was submerged as illustrated The nucleotide was added with careful stirring so as to make a final concentration of 1 mg ml^{-1} in 1 4 ml The reproducibility of the response was quite good—in five separate measurements the latency was 3 5 min and the mean decrease at the minimum was 32%±3% (s d) The growth response to a bilateral blue light stimulation (at right hand arrow) was normal in the presence of dibutyryl cyclic AMP, (0 25% Triton X-100 was present to solubilise the nucleotide Neither this nor stirring alone caused any discernable changes in growth rate)

Adenyl cyclase has been localised cytochemically using the specific inhibitor adenylyl imidodiphosphate by a method developed for islets of Langerhans[12] Cyclase is abundant in the growing zone of the sporangiophore and is not present in the nongrowing zone areas The plasmalemma, mitochondria and cytosol all have significant activity (my observations with C J M Farnham)

One might expect then that exposure to cyclic AMP would induce a transient negative growth response The sporangiophore of *Phycomyces* grows poorly under water but well in the fluorocarbon perfluorotributylamine In such a system, chemicals can be added and the response of the sporangiophore observed The introduction of dibutyryl cyclic AMP at a final concentration of 1 mg ml^{-1} consistently leads to a transient 30% decrease in the rate of growth (Fig 3) indistinguishable from the response to the dimming of light Results obtained with the phosphodiesterase inhibitor theophylline are similar This again is consonant with the hypothesis that in *Phycomyces*, modulation of cyclic AMP concentration is an important link between the reception of light and the observed transient changes in growth rate

I thank Mr D Hampshire and Mr W Farnham for technical assistance This work was supported by a grant from the National Institutes of Health.

Glucocorticoids and hCG sensitivity of rat testicular Leydig cell

THERE is unequivocal evidence that the foetal Leydig cell in the rat is under the control of gonadotrophins[1] whereas the postnatal Leydig cell is insensitive to hypophyseal luteinising hormone (LH) (ref 2) as well as to exogenous human chorionic gonadotrophin (hCG) (refs 3 and 4) We have shown recently that the hCG insensitivity of the Leydig cell during the first 2 weeks after birth is not due to the lack of the specific hCG receptor nor of an enzyme adenyl cyclase, both of which are prerequisites of hCG action[3,4] The receptor is a constitutive protein which is already present in the foetal Leydig cell[3]

??
??

It seems obvious that the apparent loss of hCG sensitivity of the Leydig cell after birth must be causally connected with the separation of the foetus from the mother It seems likely that the cells are deprived of a stimulus for growth and activity This stimulus might be another hormone which is present in the rat foetus, absent after birth and simultaneously restored with the onset of hCG sensitivity 2 weeks later The glucocorticoids of the adrenal cortex fulfil such a requirement The plasma corticosterone level is high before and shortly after birth[6], decreases to a very low level in the 12 d old rat[7] and increases again afterwards[8] Therefore we have tested whether hCG sensitivity during the insensitive period is inducible by hydrocortisone and adrenocorticotrophic hormone (ACTH) respectively Alcohol dehydrogenase (ADH, E C 1 1 1 1), an enzyme specifically located in the Leydig cell was used as a marker for Leydig cell function

Rats of strain SIV-50 were used throughout the experiments For the study of prenatal animals at a definite developmental stage, mating was determined by examining the presence of copulation plugs in the female rats (day of vaginal plug=day 1 of pregnancy) At the respective experimental days of pregnancy the animals were killed, exsanguinated and the testes of the foetuses were removed Varying numbers of animals were used in each experiment dependent on the age of animals: 20-40 foetuses, 15-20 animals between birth and day 8, 10 animals between days 9 and 13, five animals between days 14 and 16 and one animal between days 25 and 50 Each experiment was done at least in triplicate, if not otherwise stated The procedures used for the preparation of the animals and for ADH activity measurements were similar to those described earlier[3].

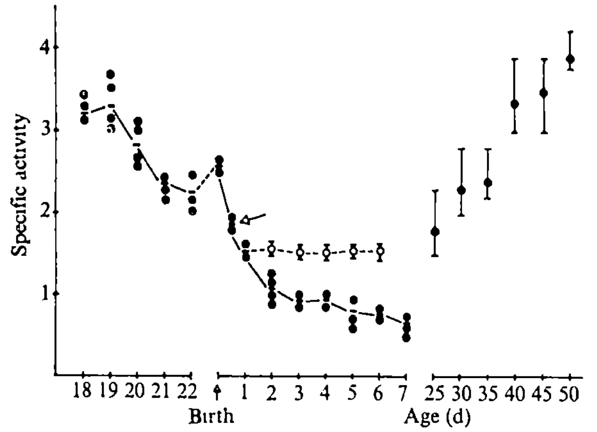

Fig. 1 Enzyme activity of alcohol dehydrogenase (mU mg^{-1} protein) in the testis of foetal and postnatal control rats and in chronically hydrocortisone treated rats Hydrocortisone acetate was purchased as Hydrocortison in a watery suspension (25 mg ml^{-1}) from Hoechst AG, Frankfurt, West Germany ●, Controls, arrow, controls 8 h after birth (each circle represents one experiment), ○ animals treated daily with 1 25 mg hydrocortisone subcutaneously from the first day after birth till to day 6 of life Preparation of the testes was performed 7 h after the last injection In hydrocortisone-treated rats and in control rats between days 25 and 50 of age at least three experiments were performed The main values and deviations are included.

As shown in Fig 1 in the day 19 foetal rat testis ADH activity is as high as in the 45 d old rat when spermatogenesis is fully established During late foetal development testicular ADH activity decreases, but the most dramatic decrease occurs during the first 2 d after birth, the lowest activity is found at 11 d of age[4] Daily injections of 1 25 mg hydrocortisone from day 1 after birth onwards till day 6 of life prevent the decrease in ADH activity Furthermore, by daily injections of 80 IU hCG in addition to hydrocortisone even the foetal enzyme activity level is restored (not shown)

We have reported recently that the postnatal Leydig cell, in spite of an intact apparatus for the response to hCG, is insensitive to the hormone during the first 2 weeks after birth[3,4] Figure 2 shows that the cell becomes sensitive to gonadotrophins after hydrocortisone or ACTH treatment After a single injection of hydrocortisone and hCG simultaneously, on each experimental day, on testicular ADH activity increases to a greater extent than after the injection of hydrocortisone alone

Figure 3 shows that a single simultaneous injection of 2 5 mg of hydrocortisone and 80 IU hCG into rats at day 6 and day 8 after birth results in a maximum increase of testicular ADH activity 31 h later Afterwards the activity decreases, and reaches nearby control levels 80-100 h after the injection Since exogenous hCG cannot stimulate ADH activity during this developmental period the decrease must be due to hydrocortisone degradation during the experimental time interval These results indicate that an adequate glucocorticoid level has to be maintained in order to guarantee hCG responsiveness of the Leydig cell As a nearly adult plasma corticosterone level is achieved in the 21-d-old male rat[8], hydrocortisone injection into rats older than 21 d should be ineffective Accordingly, testicular ADH activity in hydrocortisone-treated 26-d-old (5 0 mg per animal) and adult animals (12 5 mg per animal) corresponds to control animals 24, 31, 58, 72 and 96 h after the injection (not shown)

From our results we infer that the insensitivity of the postnatal Leydig cell to gonadotrophins is due to the lack of glucocorticoids during this developmental period The foetal adrenal cortex begins to secrete glucocorticoids on gestational day 16 or 17 (ref 9) and could therefore provide the natural stimulus for the LH sensitivity of the foetal Leydig cell The maximal concentration of corticosterone in the plasma and adrenal glands occurs between days 18 and 19 and then decreases till birth[6] The hypothalamic control of the pituitary–adrenal system begins to operate between days 18 and 22 of gestation[10] After birth, however, the pituitary–adrenal axis becomes dormant and is re-established approximately 2 weeks later, the normal control of ACTH release emerges from day 11 to maturity[11] Our ADH activity measurements in foetal and postnatal testicular tissue, as well as after hydrocortisone or ACTH treatment, are in line with these findings

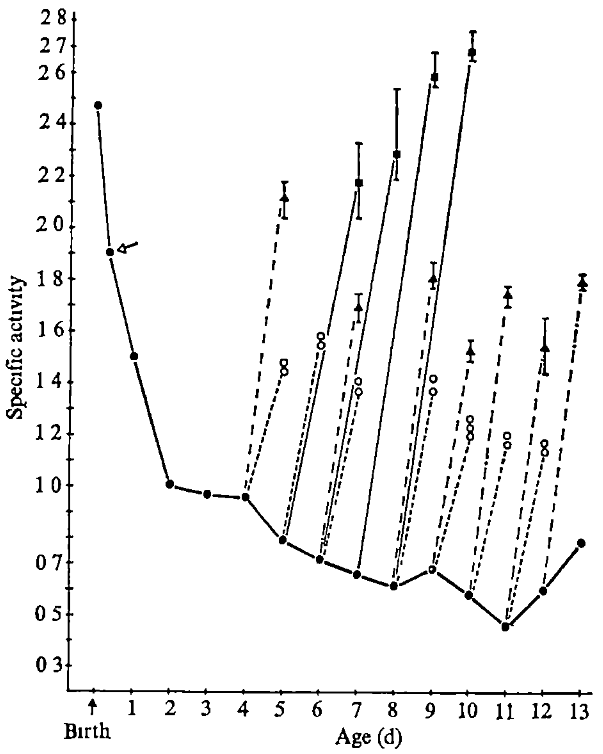

Fig. 2 Enzyme activity of alcohol dehydrogenase (mU mg^{-1} protein) in the testis of rats between birth and the day 13 of age in controls and treated animals ●, Controls, →, controls 8 h after birth (for further details see Engel and Frowein[4]), ○, animals treated with 2 5 mg hydrocortisone subcutaneously and prepared 31 h later Each circle represents one experiment ▲, Animals were injected simultaneously with 2 5 mg hydrocortisone intraperitoneally and 80 IU hCG, subcutaneously, dissolved in 0 1 ml of a 0 9% NaCl solution (preparation of the testes was done 31 h after the injections) ■, After two doses of 1 IU ACTH (dissolved in 0 1 ml of a 0 9% NaCl solution) subcutaneously at a 24 h interval The testes were removed 7 h after the last injection Mean values and deviations resulting from at least three experiments with hCG+hydrocortisone (▲) and ACTH (■) are demonstrated HCG was supplied as Primogonyl (crude hCG preparation, only hCG activity, specific activity of 3,000 IU mg^{-1} protein) from Schering AG, Berlin, West Germany Two ACTH preparations were used Depot-Acethropan (highly purified preparation from animal hypophysis, salt-like bound to polyphlerotine phosphate, exclusive ACTH activity, specific activity of 200 IU mg^{-1} protein) from Hoechst AG, Frankfurt, Western Germany and Depot-Synacthen (synthetic ACTH preparation, β^{1-24} corticotrophin hexa-acetate, the first 24 amino acids are identical to the genuine human ACTH) from CIBA-Geigy AG, Wehr, Western Germany The results obtained with both ACTH preparations were identical.

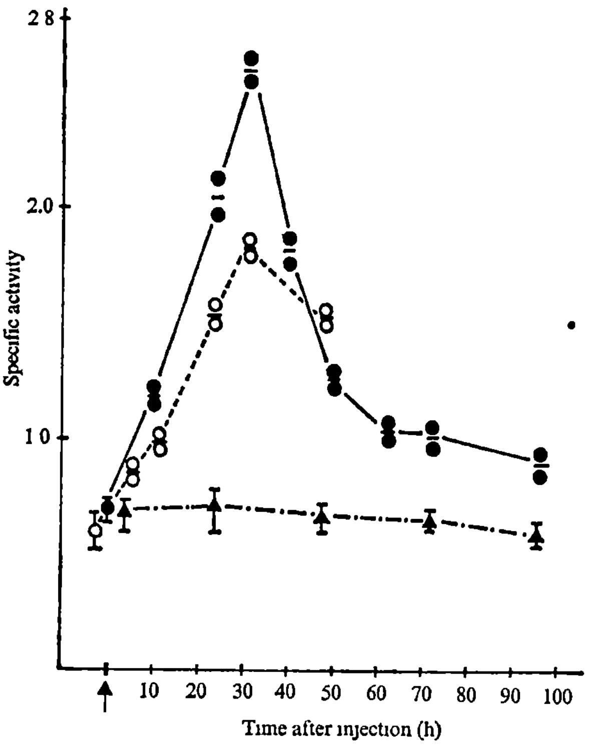

Fig. 3 Enzyme activity of alcohol dehydrogenase (mU × mg^{-1} protein) in the testis of rats at day 6 (●) and day 8 (○) of life, prepared between 5 and 98 h after a single simultaneous injection (→) of 2 5 mg hydrocortisone (intraperitoneally) and 80 IU hCG (dissolved in 0 1 ml 0 9% NaCl solution) subcutaneously Each circle represents one experiment Also ADH activities in rats between days 6 and 10 of age, daily treated with hCG, subcutaneously, from birth onwards (▲) are included in the figure, for further detail see Engel and Frowein[4].

Obviously, the adrenal glucocorticoids are necessary for the initiation of the sexual maturation process in the male rat Recently Gorski and Lawton[12] and Ramaley[13] have provided evidence that the adrenals play a definite role in determining the time of onset of puberty in the female rat In immature or adult male rats cortisone has been reported to stimulate testis weight and to effect testicular morphology (for review see Gomes[14]) Zondek and Zondek[15] found a positive correlation between hypoplasia of the adrenal cortex and the number of Leydig cells in anencephalic human foetuses Brook *et al*[16] reported a 15 9-yr-old boy with congenital adrenal hypoplasia exhibiting no signs of puberty. Furthermore, in men with Addison's disease Leydig cells seem to be sensitive to hCG only to a very small extent (E Nieschlag, unpublished) ACTH injections into prepubertal children result in a significant increase of plasma testosterone and dehydroepiandrosterone concentration[17]

The question arises by which mechanism glucocorticoids may provoke hCG sensitivity of the Leydig cell We have shown recently that hydrocortisone-1-2-^{3}H can bind to a cytoplasmic receptor in rat testicular tissue (W E , and J F , unpublished) In contrast to liver, however, the hydrocortisone receptor complex is not translocated to the nucleus (J F and W E , unpublished) Since hydrocortisone has a similar effect on ADH activity in the hCG insensitive testis as theophylline[3,4], we assume that glucocorticoids act by alteration of cyclic 3 , 5′-monophosphate phosphodiesterase activity in the Leydig cell We already have experimental evidence supporting this view (W E , and J F , unpublished) A similar effect of the glucocorticoids has been described in various other tissues[18–20].

This work was supported by the Deutsche Forschungsgemeinschaft (SFB 46) Hydrocortisone and ACTH were gemeinschaft Hydrocortisone and ACTH were generous gifts of Hoechst AG, Frankfurt, Western Germany.

Indomethacin potentiates PGE₁ stimulated cyclic AMP accumulation in human synoviocytes

PROSTAGLANDINS have both inhibitory and stimulatory effects on inflammatory and immune processes[1] The capacity of the nonsteroidal anti-inflammatory agents, aspirin and indomethacin (IM), to inhibit the synthesis of certain prostaglandins emphasises the potential importance of this hormone system in the pathogenesis and treatment of inflammatory arthritis[2] Since the prostaglandins inhibit certain cellular functions involved in the production of some forms of arthritis[3], suppress the inflammatory response of adjuvant arthritis[4-7] and yet induce an acute inflammatory response when injected into the dog stifle joint[8], there remain certain paradoxes with regard to the role of prostaglandins in inflammatory joint diseases.

We have used human synoviocytes in culture to investigate directly the effects of IM on these cells in the presence and absence of prostaglandins We report here results which demonstrate a significant increase in the intracellular concentration of cyclic AMP when human synoviocytes in culture are treated with PGE_1. Our results also show this hormone-mediated effect to be potentiated by IM, an inhibitor of human synoviocyte cyclic adenosine 3′,5′-nucleotide phosphodiesterase (PDE) activity

Human synovial lining (SLC) or tendon sheath lining (TLC) cells were dissected from underlying tissue at surgery by using a dissecting microscope, cut into small pieces and planted in growth media. When sufficient outgrowth was observed, cultures were trypsinised and subcultured for experimental use, Subcultured cells showed ultrastructural characteristics similar to those published for human type A and B synoviocytes in tissue culture[9,10] and produced significant amounts of hyaluronate using a qualitative mucin test[11]. Cells were routinely split 1 to 2 h after the first subculture had reached confluency, thus, the passage number roughly corresponds to the number of cell doublings after the first subculture. Cells were used between the fourth and twelfth passage and were mycoplasma negative Protein was measured by the Lowry method[12], and the Thompson and Appleman method[13] was used to determine PDE activity ^{3}H-cyclic AMP (28 Ci mmol^{-1}, Schwarz-Mann) was purified by thin layer chromatography[13]

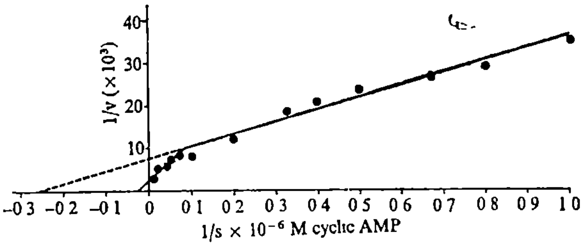

Fig. 1 Lineweaver-Burk plot of synoviocyte cyclic adenosine 3′, 5′–monophosphate phosphodiesterase activity Each point represents the average of two determinations, and the slope and intercept calculations are by linear least square analysis The maximal velocities for the low and high K_m plot are 135 and 435 pmol cyclic AMP hydrolysed per 30 min, respectively

The control values for cyclic AMP in the experiments presented (Table 1) are somewhat higher than have been determined for other nonestablished cell lines When human synoviocytes were assayed without a 1 h preincubation in serum-free media, however, we found the cyclic AMP concentration to be 18 9 ± 2 66 pmol per mg protein which is similar to the concentrations found by others in quiescent fibroblasts[14] The absence of serum for 1 h results in a two to threefold increase in intracellular cyclic AMP concentrations which agrees with the results of Froehlich and Rachmeler[15] who found an inverse relationship between intracellular cyclic AMP and media serum concentrations for human diploid fibroblasts Ethanol at concentrations up to 0 53% had no significant effect on the intracellular cyclic AMP concentrations.

IM used alone at concentrations of 10^{-4} and 10^{-5} M had little effect on intracellular cyclic AMP concentration (Table 1, experiments 1 and 2) IM at 10^{-6} M resulted in a modest decrease in cyclic AMP concentration (Table 1, experiment 1) but, the addition of PGE_1 plus IM (10^{-4} to 10^{-6} M) routinely caused a potentiation of the PGE_1 response in both TLC and SLC cell lines IM added to the cells in increasing concentrations resulted in a concentration-dependent increase in intracellular cyclic AMP over the PGE_1-stimulated levels (Table 1, column 4) The potentiation of the PGE_1 effect on intact cells occurs at concentrations of IM (10^{-5} M) known to give effective anti-inflammatory responses *in vivo* Our data (Table 1, experiment 1) demonstrating a modest decrease in intracellular cyclic AMP concentrations with very low concentrations of IM alone (10^{-6} M) suggest a mechanism involving prostaglandin synthetase (PS) inhibition At high IM concentrations, however, both PS and PDE activities might be inhibited resulting in little change in cyclic AMP The PGE_1-dependent effect of IM may be the result of an effect of IM on either cyclic AMP or PGE_1 metabolism or an effect of PGE_1 on IM metabolism, The observations that theophylline, an inhibitor of PDE activity, also potentiated the PGE_1-responsiveness of human synoviocytes (Table 1, experiment 4) and that IM is an inhibitor of epiphyseal cartilage PDE activity[19] led us to examine the effect of IM on synoviocyte PDE activity

TLC homogenates demonstrated linear PDE activity up to protein concentrations of 185 μg ml^{-1} using 1 × 10^{-6} and 1 × 10^{-4} M cyclic AMP, respectively Kinetic studies (Fig. 1), using conditions in which less than 20% of the substrate was converted to product, provided data that gave nonlinear Lineweaver-Burk plots with two apparent Michaelis constants for cyclic AMP (4 0 × 10^{-5} M and 3 9 × 10^{-6} M) Indomethacin at a final concentration of 10^{-3} M resulted in 89% inhibition of cyclic AMP–PDE activity with 1 × 10^{-6} M cyclic AMP (Table 2) and only 10 8% inhibition with 1 × 10^{-4} M cyclic AMP as substrate The concentration of IM causing 50% PDE inhibition was 1 35 × 10^{-4} M Significant inhibition of PDE activity with low and not with high substrate concentrations demonstrates a specificity for the low K_m enzyme which is presumed to represent the enzyme species most important for the physiological control of intracellular cyclic AMP concentrations The concentrations of IM to obtain 50% inhibition of the PDE activity do not reflect therapeutic concentrations of the drug Since the lysosomal system, however, accounts for the cellular uptake of indomethacin[21], intracellular concentrations may be higher than the serum concentrations of IM stated as effective for therapeutic action In addition, the loss of cell membrane integrity which results in altered receptors, transport, and concentrating mechanisms in broken cell preparations makes this assay a less competent system for studying physiological PDE activity

Table 1 The effect of PGE$_1$ and indomethacin (IM) on intracellular cyclic AMP concentration

Cell type		Cyclic AMP pmol per mg cell protein	Increment in cyclic AMP concentration above PGE$_1$–stimulated level (%)
TLC (Experiment 1)	Control (0 2% ethanol)	103 0± 18 2	
	IM (10^{-4} M)	84 0± 11 0	
	IM (10^{-5} M)	87 3± 21 4	
	IM (10^{-6} M)	68 4± 22 4	
SLC (Experiment 2)	Control (0 2% ethanol)	56 7± 19 4	
	PGE$_1$	468 6± 45 4	
	IM (10^{-4} M)	92 7± 17 8	
	PGE$_1$+IM (10^{-4} M)	869 1±107 1	85 47
TLC (Experiment 3)	Control (0 2% ethanol)	74 3± 7 0	
	PGE$_1$	1,423 7± 40 5	
	PGE$_1$+IM (10^{-5} M)	2,009 8± 57 2	41 18
	PGE$_1$+IM (10^{-6} M)	1,690 1± 98 6	18 76
SLC (Experiment 4)	Control (0 53% ethanol)	60 5± 5 2	
	PGE$_1$	156 2± 39 3	
	PGE$_1$+7-oxa-13-prostynoic acid (50 µg ml^{-1})	79 5± 24 4	
	PGE$_1$+theophylline (10^{-3} M)	848 6±175 2	
	PGF$_{1\alpha}$	38 8± 8 3	

Human synoviocytes isolated from either tendon (TLC) or synovial (SLC) linings were planted in 60×15 mm plastic culture dishes and grown to confluency using BME (Gibco) supplemented with 20% foetal calf serum, 2 mM L-glutamine, 100 units ml^{-1} penicillin and 100 µg ml^{-1} streptomycin Following a 60 min preincubation at 37° C in serum-free media, the cells were treated with either indomethacin at a final concentration between 10^{-4} and 10^{-6} M, theophylline at 10^{-3} M or an equal volume of 100% ethanol for 15 min Subsequently the cells were treated for another 15 min with either PGE$_1$ (3 µg ml^{-1}), PGF$_{1\alpha}$ (3 µg ml^{-1}) or an equal volume of 100% ethanol 7-oxa-13-prostynoic acid (50 µg ml^{-1}) was added in appropriate incubations together with PGE$_1$ All monolayers were processed by the method of Manganiello and Vaughan[16] Cyclic AMP was assayed by the protein-binding method of Gilman[17] All test compounds were solubilised in small volumes of 100% ethanol except for theophylline which was added in BME All incubations were done on duplicate plates and cyclic AMP assayed at two dilutions Appropriate control samples were assayed for cyclic AMP after the addition of purified beef heart PDE to determine the amount of nonspecific binding[18] All values shown have been corrected for this nonspecific binding Each cyclic AMP concentration given represents the mean± s d of four determinations Final concentrations in the incubation are given for each treatment.

These results and others showing that IM causes an increment in cyclic AMP in the presence of PGE$_1$ receptor-site saturation (D S N and C P C unpublished) suggest that the IM potentiation of PGE$_1$ stimulation of cyclic AMP is most likely the result of PDE inhibition

In addition to the IM effect on cyclic AMP, our experiments (Table 1) demonstrate a direct effect of PGE$_1$ on human synoviocytes PGE$_1$ increased the intracellular cyclic AMP concentration in human synoviocytes derived from both tendon sheath and synovial membrane

The specificity of the PGE$_1$ response is supported by the fact that PGF$_{1\alpha}$ did not cause an increase in intracellular synoviocyte cyclic AMP concentration, and that 7-oxa-13-prostynoic acid, a competitive inhibitor of prostaglandin binding in some systems[22], depressed PGE$_1$ responsiveness (Table 1, experiment 4)

Our results show that IM potentiates the effect of PGE$_1$ on intracellular cyclic AMP concentration by inhibiting synoviocyte PDE activity Since prostaglandins are found in inflammatory exudates[1], the PGE$_1$ effect amplified by IM may represent a new component of the anti-inflammatory effect of this drug We have also shown a PGE$_1$-mediated stimulation of human synoviocytes The effects of PGE$_1$ and IM on intracellular cyclic AMP concentration suggests that, as has been shown for other tissues[23], the inflammatory and immune responses of human synoviocytes may be regulated by this mechanism.

Table 2 Inhibition of human synoviocyte cyclic nucleotide phosphodiesterase activity by indomethacin

Indomethacin concentration (M)	PDE specific activity (units per mg protein) 10^{-6} M cyclic AMP as substrate	Inhibition (%)
Control	543	—
10^{-3}	61	89
10^{-4}	389	28
10^{-5}	516	5
10^{-6}	525	3

Monolayers were washed five times in homogenising buffer (0 04 M Tris– HCl, *p*H 8 0 containing 10 9% sucrose) at 4° C All homogenates were prepared by the method of D'Armiento *et al*[20], and 25×10^{-6} cells per 7 5 ml of homogenising buffer resulted in a protein concentration of 0 775 mg ml^{-1} One unit of PDE activity was defined as the amount of enzyme required to hydrolyse 1 pmol cyclic AMP per 30 min at 30° C Indomethacin was solubilised in DMSO, and control and experimental incubations contained in final concentration 1 25% DMSO Appropriate control incubations established that the observed effects of IM on PDE activity were not the result of 5′–nucleotidase inhibition All assays were run in triplicate

These investigations establish a role for prostaglandins and cyclic AMP in the biological function of human synoviocytes and propose a new mechanism for the anti-inflammatory activity of indomethacin

We thank Dr Philip Davis for providing the surgical specimens The work was supported by grants from the National Institutes of Health and The Arthritis Foundation The prostaglandins were a gift from Dr John Pike of Upjohn Company, the indomethacin from Dr T Y. Shen and the 7-oxa-13-prostynoic acid from Dr F A Kuehl, jun both of Merck, Sharp and Dohme

Blockage of cation permeability across the tight junctions of gallbladder and other leaky epithelia

THE main route of passive ion permeability in gallbladder and other 'leaky' epithelia is through the so-called 'tight' junctions between cells, not through the cells themselves[1] I report here that the protonated form of the organic base 2,4,6-triaminopyrimidine (TAP), reversibly and specifically blocks cation permeation across this tight junction route in frog gallbladder and several other leaky epithelia Since in these epithelia the tight junction permeability is mainly (or even completely) cationic, in principle on addition of TAP a low resistance, leaky epithelium can become a high resistance epithelium

Transepithelial electrical potential differences (p d) and conductances (G) were measured across flat sheets of bullfrog gallbladder mounted between two well-stirred chambers at 23° C The experimental procedure, and methods for obtaining ionic permeability (P_{II}) and conductance (G_I) values (correcting G_{Na} for a small leakage current) were described previously[2] The rate of fluid transport was measured in 'sac' preparations of bullfrog gallbladder by the gravimetric procedure described in detail by Diamond[3] Since 2,4,6-triaminopyrimidine (pK_a = 6 72) is only active in the protonated form (manuscript in preparation), all the experiments were done at pH 6 0, and only concentrations of the protonated form are reported TAP was effective when added to the mucosal, serosal, or both solutions, but in the experiments reported here it was added symmetrically to both sides of the preparation

Addition of TAP invariably increases the membrane resistance (R_m) and decreases the P_{Na}/P_{Cl} ratio Both effects are totally due to a specific decrease in G_{Na} Let us define the fractional inhibition (α) of the partial conductance of an ion X as $\alpha_X \equiv 1 - [G_X\ (\text{TAP})/G_X\ (\text{control})]$, where G_X (control) and G_X (TAP) are the conductances of the ion species X in the control period and in the presence of TAP respectively Each point of Fig 1*b* represents an experimental α_{Na} determination in an individual frog gallbladder at a given TAP concentration The figure shows that as the TAP concentration increases α_{Na} approaches 1, that is, G_{Na} is reduced At 19 mM 92% of G_{Na} is inhibited The dependence of α_{Na} on TAP concentration suggests a saturation kinetics Therefore, the experimental values were fitted by the equation

$$\alpha_{Na} = C\,[\alpha_{Na}\ (\max)]/[K_m + C] \qquad (1)$$

where C represents the concentration of TAP, and α_{Na} (max) and K_m are two constant parameters The curve drawn through the experimental α_{Na} values of Fig 1*b* is based on the least mean squares fit of the experimental values to equation 1 The fitted parameters and their standard deviation are K_m = 2 6 ± 0 1 mM, and α_{Na} (max) = 1 0 ± 0 0 This indicates that 100% of G_{Na} can be inhibited by TAP at sufficiently high concentrations, and that the inhibitory process can be described by a single constant

The situation for G_{Cl}, illustrated in Fig 1*a*, is very different at all TAP concentrations tested $\alpha_{Cl} \simeq 0$, meaning that TAP does not affect G_{Cl} This indicates that Na^+ and Cl^- migrate through separate pathways, and is in agreement with previous evidence[4] suggesting that the Cl^- pathway is a relatively small ($G_{Cl}/G_{Na} \simeq$ 0 2 in untreated frog gallbladder) parallel leakage or free solution shunt

In five other leaky epithelia[1] (six rabbit gallbladders, two *Necturus* gallbladders, two rabbit small intestines, two bullfrog small intestines, and two bullfrog choroid plexuses) TAP had qualitatively the same effect as in frog gallbladder In all cases TAP increased R_m and decreased P_{Na}/P_{Cl}, and the effect could be completely attributed to an inhibition of G_{Na}

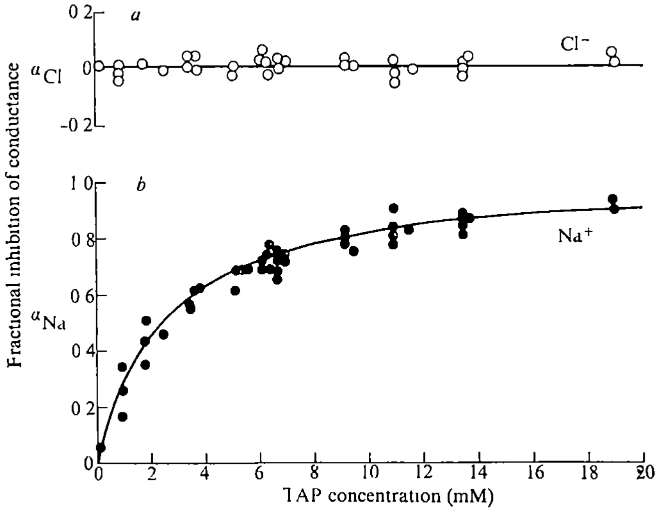

Fig 1 Effect of TAP on G_{Na} and G_{Cl} The fractional inhibition of G_{Na} (●, α_{Na}, below) and G_{Cl} (○, α_{Cl}, above) are plotted against TAP concentration Each point corresponds to one experimental value Notice that G_{Na} is strongly inhibited (α_{Na} increases) as TAP concentration increases, whereas G_{Cl} is unaffected The line drawn through the α_{Na} values is the least mean squares fit to equation 1 yielding K_m = 2 6 mM, α_{Na} (max) = 1 0 The line through the G_{Cl} values is the line of identity $\alpha_{Cl} = 0$

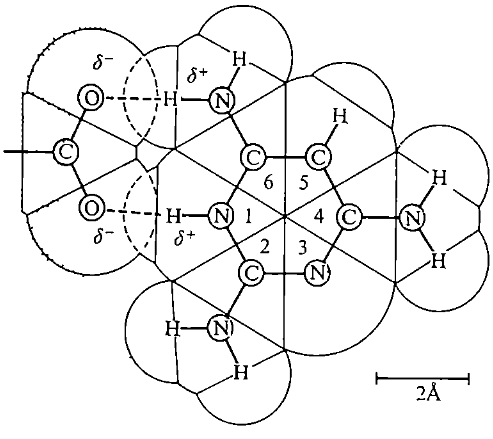

Fig 2 Scale drawing of a molecule of TAP associated by two hydrogen bonds to a carboxylic group The outline gives the van der Waal's surface, the heavy lines inside represent the internal covalent bonds, the broken lines represent hydrogen bonds The van der Waal atomic radii, bond lengths and angles are taken from Corey-Pauling-Koltun models Notice the good fit of the two hydrogen bonds If a $-PO_4H^-$ group is used instead of a $-COO^-$ group, the fit of the hydrogen bonds is equally good The shadow limit represents a ring of radius 6 Å, an equivalent radius attributed to bullfrog gallbladder tight junction cation channels[2,4]

The gallbladder actively transports an isotonic solution from the mucosal side The rate of this fluid transport measures (and is caused by) active transport of Na^+ from the mucosal to the serosal solutions[3] In the absence of $NaHCO_3$ in the solutions the rate (average ± s e) of the fluid transport in six frog gallbladders was 3 9 $\pm$ 0 6 μl h^{-1} cm^{-2}, and after addition of 10 mM TAP, 3 8 $\pm$ 0 8 μl h^{-1} cm^{-2} When 7 mM $NaHCO_3$ (which stimulates active transport[3]) was included in the bathing solutions, the rate of transport increased to 9 8 $\pm$ 1 5 (n = 3) μl h^{-1} cm^{-2} in the control, and to 9 9 $\pm$ 1 9 (n = 3) μl h^{-1} cm^{-2} in the presence of 10 mM TAP Therefore TAP at a concentration which blocks 80% of the transepithelial Na^+ conductance does not seem to interfere with active Na^- transport in frog gallbladder nor affect HCO_3^- stimulation of transport

A similar conclusion can be reached from a completely different observation in 24 frog gallbladders TAP (5–11 mM) increased R_m and the spontaneous transepithelial p d (V_m) from 129 $\pm$ 7 Ω cm^2 and 2 2 $\pm$ 0 2 mV (serosa positive), to 257 $\pm$ 12 Ω cm^2 and 4 8 $\pm$ 0 4 mV respectively But the ratio V_m/R_m (analogous to an open circuit current and hence a measure of active Na^+ transport) did not change significantly (17 1 $\pm$ 1 4 μA cm^{-2} for the control, against 18 3 $\pm$ 1 3 μA cm^{-2} after TAP) These results add to the growing evidence in support of an electrogenic Na^+ transport rather than the original suggestion[5] of an electrically neutral mechanism as responsible for active Na^+ transport in gallbladder (see ref 4 for further discussion)

Therefore, I conclude that in frog gallbladder TAP acts specifically in the cation-selective ion channels of the tight junction responsible for the passive Na^+ permeability[1,4] without affecting either the small Cl^- leakage current or the active Na^+ transport

From studies on the cation permeability and selectivity in frog gallbladder[2,4] these channels are thought to be hydrated and relatively large (the estimated radius is 6–8 Å) Their Na^+ conductance is controlled by acidic groups whose apparent pK_a is 4 4 The cation ligands in the channel (probably the same acidic groups) behave as strong hydrogen bond proton acceptor sites which distinguish more strongly among cationic proton donors than does water[6]

The protonation of TAP occurs at one of the ring nitrogen atoms (see Fig 2), but the net charge is delocalised by resonance, and shared with the 2,4 and 6 amino groups[7] Therefore, TAP should be a strong H bond proton donor The H bond association illustrated in Fig 2 between a molecule of TAP with a $-COO^-$ group (or a $-PO_4H^-$ group, although it is not shown in the figure) could be particularly strong, because the atoms involved in the H bonds have high partial ionic character and form appropriate angles between the internuclear lines (Fig 2) Actually, ion pair formation between phosphate ions and 2,4-diaminopyrimidine in relatively dilute aqueous solutions has been reported and attributed to H bond associations such as those illustrated in Fig 2 (ref 7) Indeed, these characteristics of TAP as a strongly H bonding proton donor were what led me to try it as a blocker of the strongly H bonding acceptor sites in gallbladder channels

Probably the value of K_m (equation 1) extracted from Fig 1 reflects the affinity constant of the binding of TAP with the ligands of the channel The ligands presumably bind TAP so strongly (compared with their binding to Na^+) that TAP is relatively immobilised and blocks the ligands and channel for Na^+ This affinity could result from an H bonded association of TAP with the strongly proton acceptor acidic groups of the channel, as illustrated in Fig 2

Figure 2 is only an attempt to explain the relatively high affinity of TAP to the acidic ligands of the channel, but other bonds and forces could be important By studying this interaction in detail, more information on the molecular structure of the channel is expected to be elucidated The tight junction cationic conductance accounts for most of the passive ionic transepithelial permeability in gallbladder (and probably most leaky epithelia) Because of its specificity and effectiveness in blocking this cation conductance, TAP constitutes a potential tool for the study of epithelial physiology and provides a pharmacological way of specifically controlling the ionic permeability across leaky epithelia

I thank Drs J M Diamond, G Eisenman and E M Wright for suggestions, and Dr Diamond for providing me with the facilities of his laboratory This work was supported by grants from the National Institutes of Health

Platelet macroglycopeptide

EVIDENCE from electron microscopy[1,2], chemical analyses of purified membranes[3,4] and the use of specific membrane labelling procedures[5], has demonstrated the presence of a carbohydrate-rich layer on the surface of the blood platelet This layer contributes many of the groupings[6] which give rise to the net electronegative charge on the outer surface of the plasma membrane There is evidence to suggest that the surface-bound carbohydrate is unusual in the platelet both in terms of the large size of the constituent glycoprotein units[7] and in the relatively high density of the terminal acidic monosaccharide, sialic acid[8]

Within the functions of the platelet as a haemostatic cell, various species differences have been shown to exist in terms of the response of the platelet to various stimuli such as ADP, 5-HT and adrenaline[9] But no differences have yet been shown in the structure of the plasma membrane, elements of which contain the groupings with which external stimuli first come into contact Here I have investigated the nature of the surface glycoprotein by examining the timed release of acidic glycopeptides from washed platelets by trypsin, followed by their characterisation on polyacrylamide gels Washed platelets obtained from human, patas monkey (*Erythrocebus patas*) and rabbit blood have been examined in this way A comparison of the glycopeptides released is shown in Fig 1

Trypsin digestion resulted in the rapid release of acidic glycopeptide, as located by Alcian Blue staining, in each of the three species examined With a digestion time of 1 min, one major band could be seen with only traces of others After 30 min digestion, however, a more complex pattern was apparent Two (human), four (rabbit) and six (patas monkey) bands were present, each band representing a glycopeptide, or class of glycopeptides of differing size or charge

Electrophoresis was performed employing standard 7% acrylamide separating gels[10] Staining capacity was adjudged to be due to complex formation between the Alcian Blue and terminal sialic acid moieties of the constituent oligosaccharide chains of the glycopeptides The staining capacity was lost following removal of the sialic acid by previous incubation with neuraminidase It was noticed that after 30 min digestion, the intensity of the first released glycopeptide was much reduced To ascertain whether the new bands were formed by further digestion of the platelet surface or by hydrolysis of the first glycopeptide, 1 min supernatants from rabbit platelet digests were concentrated, fractionated on Sephadex G-200, and the eluted fractions containing the glycopeptide again subjected to digestion with trypsin for 30 min in conditions identical to those of the original digestion of the washed platelets After 30 min, a similar glycopeptide pattern was obtained to that shown in Fig 1 Thus, it would seem that the later bands are produced as a result of hydrolysis of a single glycopeptide precursor. The major bands as now seen for each species appeared to resist further digestion by trypsin and were still present even after 18 h digestion

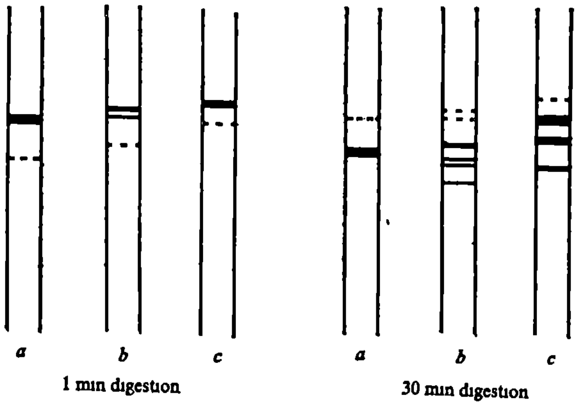

Fig. 1 Washed platelets (2 × 10^{9} ml^{-1}) suspended in 0 01 M Tris-HCl, *p*H 7 4, containing 0 15 M NaCl, 3 mM EDTA and 0 35% bovine albumin, were incubated in the presence of trypsin (0 2 mg ml^{-1}) at 37° C At selected time intervals aliquots were removed and added to soybean trypsin inhibitor (0 4 mg ml^{-1}) The platelets were sedimented by centrifugation at 1,500*g* at 4° C and 0 1 ml aliquots of the supernatant were transferred to 7% polyacrylamide separating gels (0 5 × 7 5 cm) in an even suspension of Sephadex G-25 powder A small aliquot of bromophenol blue was added as an internal reference standard Electrophoresis was performed at 200 V (constant voltage) for 1 25 h The gels were stained overnight in 1% Alcian Blue in 2% acetic acid, destained electrophoretically, and stored in 7% acetic acid at 4° C *a*, Human, *b*, patas monkey, *c*, rabbit,

Aliquots of the 1 min supernatants were also subjected to electrophoresis in the presence of the detergent sodium dodecyl sulphate (SDS) using an adaptation of the method of Weber and Osborn[11] One major glycopeptide band was seen for each species, the approximate molecular weight of which varied between 168,000 for the rabbit, 147,000 for the human and 142,000 for the patas monkey (Fig 2)

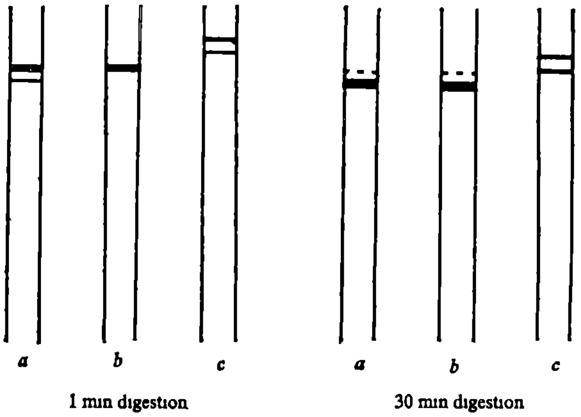

Fig. 2 Aliquots of the trypsin digest supernatants were incubated for 1 h at 37° C in the presence of 1% SDS and 1% 2-mercaptoethanol Following overnight dialysis against 0 01 M phosphate buffer, *p*H 7 1, containing 0 1% SDS and 0 1% 2-mercaptoethanol, glycerol and bromophenol blue were added to give final concentrations of 10% (w/v) and 0 02% (w/v) respectively Aliquots of 0 1 ml were applied to 7% (w/v) polyacrylamide gels containing 0 1% SDS and electrophoresis performed as described by Weber and Osborn[11] Glycopeptide was located by the periodate Schiff reaction[12] and molecular weight determinations made in comparison with the relative migration of a series of protein standards[11] *a*, Human, *b*, patas monkey, *c*, rabbit

After 30 min digestion, there was still one glycopeptide band in the human and patas monkey samples, however the approximate molecular weight of this band had fallen to 124,000 and 126,000 respectively In the rabbit two bands of molecular weight 144,000 and 159,000 were present In view of possible interference from sulphate groups contributed by the detergent, glycopeptide was here located by the periodate Schiff reaction[12] Substitution of this staining procedure for Alcian Blue in the characterisation of the glycopeptides of the 1 and 30 min digests as illustrated in Fig 1 showed no alteration in the pattern obtained, indicating a probable absence of large neutral glycopeptides

No difference in any of the electrophoretic patterns described was seen during examination of a number of individuals of each species Thus, it would seem that the glycopeptide patterns obtained were characteristic of the species examined The initial release of a large glycopeptide was common to each, though there were variations in the size of this molecule Later degradation of the parent glycopeptide by trypsin revealed differences in the number of glycopeptides obtained This is indicative of differences in the composition of the parent molecule, both in terms of its size and the number of acidic moieties carried So some differences in the molecular composition of the surface glycoprotein components of platelets of different species are apparent, though the possession of a large parent glycopeptide is common to each of the species examined here Further investigation of the role of the surface glycoproteins is suggested to determine their role in the reception of external stimuli and in governing the permeability of molecules to inner regions of the membrane

Amplification of a circular segment of SV40 DNA

DURING serial undiluted passage of simian virus 40 (SV40) in monkey kidney cells, the viral genome undergoes genetic rearrangements involving the incorporation of cellular DNA sequences[1–5] as well as deletions and reiterations of specific viral DNA sequences[3,6–8] In previous work[7], a mutant of an SV40 variant (DAR, refs 9–11) was identified after serial passage of DAR virus in primary green monkey kidney cells This mutant DNA was physically mapped by hybridising it to specific DNA segments produced by restriction endonuclease cleavage of SV40 DNA[8] The mutant DNA was found to contain only one-third of the SV40 genome which was reiterated three times to produce a DNA molecule the size of wild-type SV40 ($3\ 2\times10^{6}$ daltons) Most of the early gene sequences and a portion of the late gene region[12] were deleted from the triplicated segment, but it retained the normal site for initiation of viral DNA replication[8]

The restriction endonuclease from *Escherichia coli*, R *Eco*RI, introduces one unique cleavage in SV40[13,14] or DAR[15] DNA to yield unit length linear molecules with short cohesive termini[16] In the DAR triplication mutant, the R *Eco*RI site is symmetrically triplicated, therefore, after R *Eco*RI cleavage, segments are formed which are one-third the size of SV40 (DAR) DNA[7]

In this study, the one-third segments (10 4S DNA) arising after R *Eco*RI cleavage of DAR DNA have been isolated These segments, which contain cohesive termini, have been purified, converted to hydrogen bonded circles and covalently closed by phage T4 polynucleotide ligase to produce circular DNA segments ('minicircles') We have used the purified 'minicircular' molecules to infect monkey kidney cells in the presence of helper SV40 DNA molecules

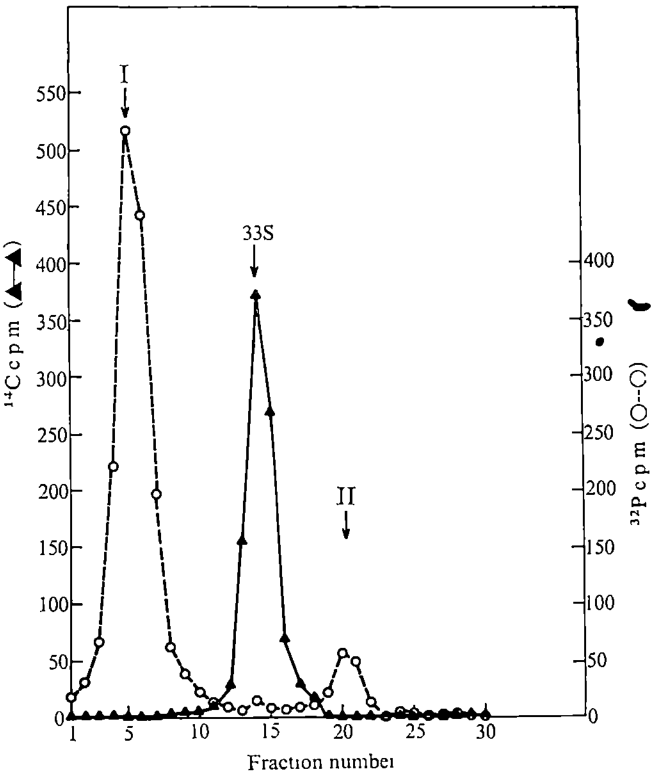

Fig 1 Analysis of minicircular DNA by alkaline sucrose sedimentation The minicircular DNA, formed by ligase treatment of 10 4S segments, was mixed with a sample of ^{32}P-labelled SV40 DNA I (53S) and II (16S) and then sedimented through a 5–20% alkaline sucrose gradient for 130 min at 50,000 r p m in the SW 50 1 rotor[19] DAR ^{14}C DNA I (ref 17) was cleaved in a reaction mixture (0 5 ml) consisting of 67 mM Tris-HCl, (*p*H 7 6), 10 mM $MgCl_2$, 15 μg of DAR viral DNA, and 0 015 ml of R *Eco*RI[7] (10^4 units ml^{-1}) After incubation at 37° C for 30 min, the reaction was stopped by chilling to 0° C and adding 10 μmol of EDTA (*p*H 8 0) The 10 4S DNA segments were isolated by sedimentation through a 5–30% neutral sucrose gradient using the Spinco SW41 type rotor[7] The pooled fractions were extracted three times with redistilled phenol and dialysed extensively against 0 01 M Tris-HCl (*p*H 7 5), 0 01 M NaCl, and 0 001 M EDTA at 4° C The ligase reaction mixture (5 ml) consisted of 66 mM Tris-HCl (*p*H 7 6), 7 mM $MgCl_2$, 70 μM ATP, 5 μg of 10 4S DNA and 1 5 units of phage T4 ligase[17] After 16 h at 18° C, additional ATP (0 35 μmol) and ligase (1 5 units) were added and the incubation was continued for 5 additional hours Then EDTA was added to a final concentration of 14 mM and the minicircular DNA was purified in an ethidium bromide-CsCl density gradient containing 200 μg ml^{-1} of ethidium bromide[19]

Mertz and Davis[16] have demonstrated that DNA molecules cleaved by endonuclease R *Eco*RI can be converted to closed circles *in vitro* because short cohesive termini are created by the staggered nucleolytic cleavage A DAR^{14}C-DNA I preparation, containing 80% triplicated DNA, was cleaved with endonuclease R *Eco*RI and the 10 4S DNA segments were purified by neutral sucrose rate zonal centrifugation[7] Minicircles were then formed from the 10 4S linear segments using bacteriophage T4 polynucleotide ligase[17], at a final DNA concentration of 1 μg ml^{-1} on order to prevent the formation of concatamers and circular oligomers[16] Approximately 80% of the 10 4S segments were covalently closed in the ligase reaction After the prolonged incubation at 18° C, the covalently closed, circular DNA was purified by dye-density gradient centrifugation A portion of the heavy band material was then analysed by alkaline sucrose sedimentation (Fig 1) The minicircles of DAR (SV40) DNA have a sedimentation value of 33S as compared to 53S for superhelical SV40 DNA I molecules No other DNA species such as dimeric or other oligomeric forms of the 10 4S segments were detectable

When the CV-1 line of monkey kidney cells[18] was infected with the purified minicircles in the absence of SV40 DNA I, there was no detectable incorporation of ^{3}H-thymidine

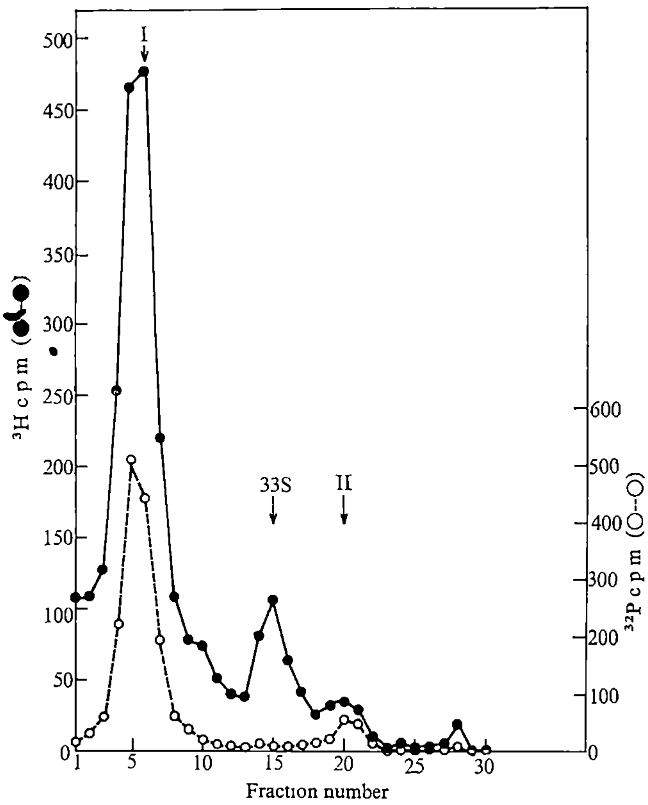

Fig 2 Alkaline sucrose sedimentation analysis of intracellular DNA I from CV-1 cells infected with SV40 and minicircular DNA All DNA infections were performed according to the method of McCutheon and Pagano[20] Thus for infection with minicircular ^{14}C-DNA, or infection with SV40 DNA I and the minicircular DNA together, confluent monolayer cultures of CV-1 cells[18] in 75 cm^2 plastic flasks (Falcon) were rinsed twice with 20 ml portions of warm PBS (0 008 M Na_2HPO_4, 0 0015 M KH_2PO_4, 0 14 M NaCl, and 0 003 M KCl) The DNA sample (0 8 ml) was then added to 0 4 ml of DEAE-dextran (2 mg ml^{-1} in PBS) to give a final concentration of 2 μg ml^{-1} for SV40 DNA, and 0 5 to 1 0 μg ml^{-1} for the minicircular DNA For infection with SV40 DNA and the minicircular DNA together, the final concentration of each DNA was the same as in the individual infections At 60–70 h after DNA infection of CV-1 cells, the medium (Eagle's MEM) was removed and replaced with medium containing 100 μCi ml^{-1} of ^{3}H-thymidine (6 ml per flask, 50 Ci mmol^{-1}) After 2 h at 37° C, the viral DNA was extracted by the method of Hirt[21] and the supernatant solution was dialysed against 0 01 M Tris-HCl, (pH 7 5), 0 01 M NaCl, 0 001 M EDTA at 4° C Superhelical viral DNA was purified by two cycles of equilibrium centrifugation in CsCl–ethidium bromide density gradients and analysed as described in the legend to Fig 1

into superhelical molecules banding with SV40 DNA I in dye-density gradients or sedimenting at 33S in alkaline sucrose This was not unexpected since the 10 4S DNA segments lack most of the early region for SV40 gene expression[8] In contrast, when cells were infected with approximately equivalent numbers of minicircular and SV40 DNA molecules, ^{3}H-thymidine was incorporated into superhelical molecules having the same density as SV40 DNA I in dye-density gradients (data not shown) When the purified, ^{3}H-labelled, superhelical DNA was analysed by alkaline sucrose sedimentation (Fig 2), a major peak at 53S and a minor peak at 33S were observed These results suggest that replication of the minicircular segments requires one or more gene product supplied by the helper genomes

The composition of the superhelical, ^{3}H-labelled DNA from the mixed infection was further analysed by neutral sucrose rate zonal centrifugation In Fig 3*a*, it is evident that, in addition to molecules sedimenting at 21S (viral genomes of normal size) and at 13 5S (superhelical minicircles), a substantial fraction (26%) of the DNA sedimented more rapidly than SV40 DNA I A portion of this heterogenous, superhelical DNA preparation analysed in Fig 3*a*, was digested with endonuclease R*Eco*RI and analysed by neutral sucrose sedimentation (Fig 3*b*) Two major bands with peaks at 14 5S (SV40 DNA III) and at 10 4S (one-third segments) were identified The proportion of molecules (37%) yielding 10 4S segments after cleavage was unexpectedly large considering that the 13 5S band in Fig 3*a* comprised only 7% of the labelled DNA This suggested that part of the 10 4S DNA was present in DNA molecules which were larger than one third of the size of SV40 DNA

In order to determine whether 10 4S DNA segments had been triplicated or more extensively amplified, different regions of a preparative neutral sucrose gradient were pooled as indicated in Fig 3*a* on the horizontal, solid line (pools A–D)

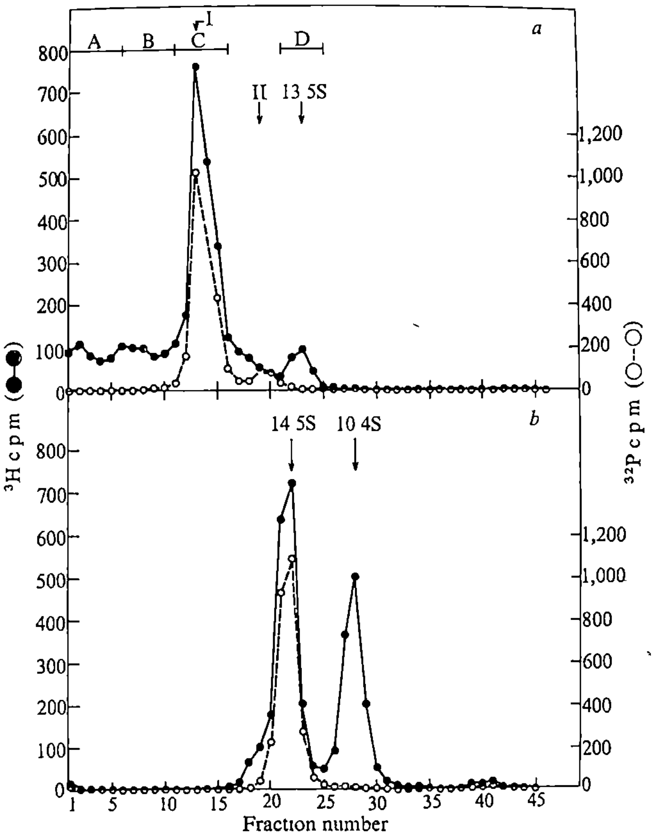

Fig. 3 R*Eco*RI cleavage of intracellular DNA I from CV 1 cells infected with SV40 and minicircular DNA Superhelical viral DNA was isolated as described in the legend to Fig 2 and analysed[19] by neutral sucrose gradient centrifugation (7 h, 40,000 r p m) in the Spinco SW41 rotor before (*a*) and after (*b*) cleavage with R*Eco*RI

Each of these DNA preparations was analysed separately before and after R*Eco*RI cleavage by neutral sucrose sedimentation (Fig 4) Fractions from pool A (Fig 4*a*) comprised 12% of the total superhelical DNA and had an average sedimentation value of 27 6S (molecular weight= 5 7×10^6, ref 22) After R*Eco*RI cleavage (Fig 4*d*), a peak at 10 4S (51% of pool A) was present with two less well defined peaks at 14 5S and at 16 7S Pool B (Fig 4*b*) had an average sedimentation value of 25 3S (molecular weight =4 7×10^6) and, after cleavage (Fig 4*e*), produced molecules which sedimented at 14 5S (25%) and at 10 4S (64%) After cleavage of pool C, which sedimented with SV40 DNA I (21S), 78% of this DNA sedimented at 14 5S while 18% had a sedimentation value of 10 4S Pool D (data not shown) produced only 10 4S DNA after cleavage, as ex-

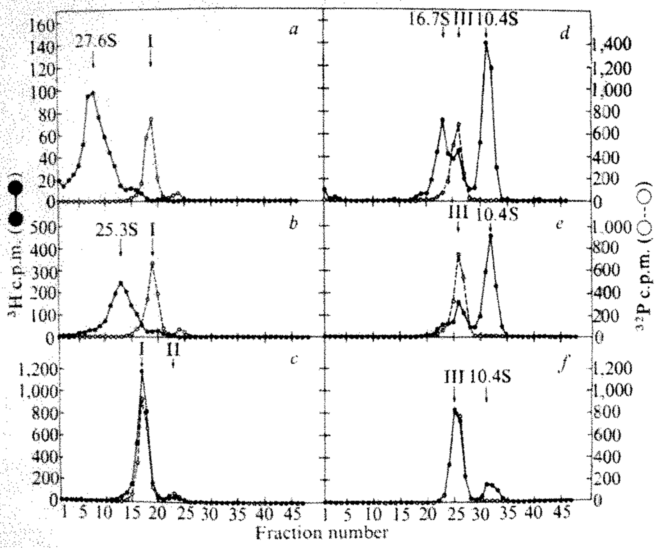

Fig. 4 Analysis of partially fractionated oligomers isolated from cells infected with SV40 and minicircular DNA. Different regions of a preparative neutral sucrose gradient similar to Fig. 3*a* were pooled as indicated in Fig. 4*a* on the horizontal solid line. Each of these DNA preparations was then analysed separately before and after cleavage by R·*Eco*RI as described in the legend to Fig. 3. The analyses of pool A are shown in *a* (before cleavage) and *d* (after cleavage), pool B in *b* and *e* and pool C in *c* and *f*.

pected. These results show that molecules of much higher molecular weight than the minicircular DNA are a source of 10.4S DNA after R·*Eco*RI cleavage and suggest that amplification of the 10.4S segments had occurred producing circular oligomers of this segment.

When the mixed infection of CV-1 cells with minicircular and SV40 DNA was allowed to proceed to completion, the virions purified from the lysate formed only one band in a CsCl density gradient[11]. DNA extracted from the purified virions sedimented in a narrow band in a neutral sucrose gradient at the position of SV40 DNA I (data not shown). Thus, only molecules having the same size and shape as SV40 DNA were encapsidated. After R·*Eco*RI cleavage of the DNA from virions, molecules sedimenting at 14.5S and 10.4S were found, indicating that trimeric genomes had been encapsidated. Furthermore, cleavage of these 10.4S segments with the restriction endonuclease from *Hemophilus influenzae* produced five fragments having the same electrophoretic mobility as those produced from the original 10.4S DNA[8].

These results indicate that circular, duplex viral DNA segments much smaller than SV40 DNA can be replicated *in vivo*. In addition they support the model proposed by Khoury *et al.*[8] for the generation of the original DAR triplication mutant. In our experiments, cells were infected with a minicircular DNA molecule, formed *in vitro*, which then served as a precursor *in vivo* in the formation of trimers and higher oligomers as predicated by the proposed model. The DAR triplication mutant first appeared after the third passage in primary monkey kidney cells and rapidly became the predominant species in later passages[7]. This mutant may have had a strong selective advantage since it contained three sites for initiation of DNA synthesis. The oligomeric forms in our studies may have evolved for a similar reason.

We thank Drs M. A. Martin, G. Khoury, and C. C. Richardson for discussions and suggestions. Phage T4 polynucleotide ligase was kindly provided by Dr C. C. Richardson. Leukaemogenic effect of repeated inoculations with small doses of Tennant virus in BALB/c mice

DOSE-RESPONSE studies of oncogenic viruses in animals are usually restricted to single inoculations. The study of the effect of dose fractionation has been a rather neglected subject in this field. An important question is whether the combined effect of the small doses is less than the effect of a single exposure to the same total dose. In this study on dose fractionation of a murine leukaemia virus we observed the opposite effect.

The B/Tennant leukaemia virus was isolated from a spontaneous lymphosarcoma of BALB/c mice[1]. It usually induces this disease in BALB/c mice with a relatively short latency period[1–3]. Dr J. Tennant (Sloan–Kettering Institute, New York) sent us a sample of the virus in 1969 and we then passed it continuously by inoculations of crude cell-free extracts of leukaemic tissues into neonate BALB/c mice. For the present study, 1 l of a 10% cell-free extract was prepared as previously described[4] and stored in liquid nitrogen in 10 ml aliquots. Intraperitoneal inoculations with virus were started in female BALB/c mice (20 per group) when they were six weeks old.

Table 1 Leukaemia incidence and latency in BALB/c mice repeatedly injected with Tennant murine leukaemia virus

Virus dilution	Number of inoculations 1	3	6	12	As many as possible till autopsy
10^{-1}	100 (44±8)*	100 (43±5)	100 (38±10)	100 (41±8)	100 (35±4)
10^{-2}	100 (49±5)	100 (49±6)	100 (47±6)	100 (43±5)	100 (47±7)
10^{-3}	100 (80±18)	100 (67±22)	100 (59±11)	100 (58±15)	100 (49±6)
10^{-4}	35 (109±3)	20 (82±14)	75 (79±19)	100 (64±20)	100 (56±13)
10^{-5}	0	0	25 (121±18)	65 (74±14)	100 (69±20)
10^{-6}	0	0	0	80 (99±8)	100 (72±11)

* %Incidence (latency period (d) ± s.d.).
† The average number of injections in these series is 15, 19, 20, 22, 28 and 29 respectively.

The mice were injected three times a week. They were examined twice a week for splenomegaly and/or swollen lymph nodes. The animals were then autopsied and histologically examined for confirmation of the development of leukaemia. The survivors were kept under observation only up to the age of 10 months. After that age, the first spontaneous lymphoreticular neoplasms begin to appear in this strain.

From the results in Table 1, it is obvious that a 1,000-fold dilution is still fully leukaemogenic. Higher virus doses or repeated inoculations tend to shorten the latency period. There is no indication that dose fractionation leads to a lower incidence or longer latency.

In fact we found that repeated inoculations with low doses of virus produce a significantly higher leukaemia incidence than a single injection with a much higher dose (for instance, 12×10^{-6} instead of 1×10^{-4}). A possible explanation is that continuous exposure to even very small numbers of virus particles induces immunological unresponsiveness to the virus, so that these small numbers may be propagated in the host. Alternatively, autointerference induced by a moderate dose of virus may play an important part.

It would be worthwhile to investigate whether a similar procedure can overcome the genetic resistance of some mouse strains to the virus[2,5], as well as that of adult rats. The observation must be extended to other tumour virus systems. If it proves to be of a general nature, it has important biohazard implications for tumour virological workers or investigators handling cell cultures which produce small amounts of C-type oncornavirus particles[6].

New Giemsa method for the differential staining of sister chromatids

If human lymphocytes[1] or Chinese hamster[2] cells are treated with the base analogue 5-bromodeoxyuridine (BrdU) in the latter part of the S period, Giemsa stained chromosomes exhibit a pattern of condensed and extended segments along their length. This phenomenon has been attributed to a delay in the spiralisation pattern of the late replicating regions along the chromosomes. Other experiments[3] with Chinese hamster ovary (CHO) cells have shown that after two rounds of replication in the presence of BrdU or IdU, sister chromatids stain differentially with Giemsa, allowing the identification of the two chromatids, and the observation of sister chromatid exchanges (SCEs) without recourse to autoradiography. The chromatid with the bifilarly substituted DNA (BrdU substituted in both strands of DNA) is less condensed and stains more weakly with Giemsa than the unifilarly substituted sister chromatid. The yield of SCEs is approximately that observed by autoradiography.

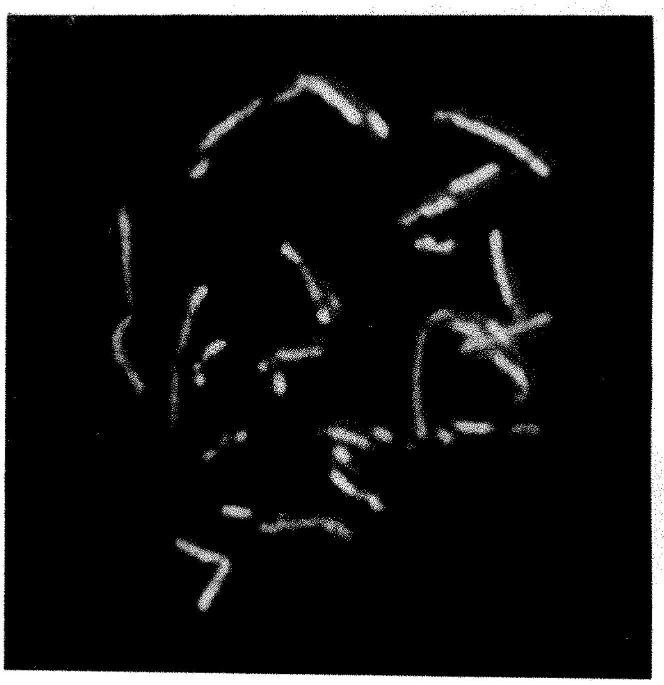

Fig. 1 CHO cell stained with Hoechst 33258 after two rounds of replication in the presence of BrdU. Fluorescence performed as in ref. 4. Leitz ortholux microscope, 200 W mercury light source UG-1 filter and TK400 dichroic mirror for excitation, and K400 and K430 barrier filters.

Latt[4] has described a fluorescence technique for human chromosomes using the dye Hoechst 33258. This dye normally fluoresces intensely when bound to poly(dA-dT), but when bound to poly(dA-BrdU) the fluorescence of the dye is quenched. After two rounds of replication in the presence of BrdU, followed by staining in Hoechst 33258, the unifilarly substituted chromatids fluoresced more brightly than the bifilarly substituted sister chromatids. Sister chromatid exchanges were readily observed. Though this technique provided a degree of resolution for the detection of SCEs which was previously not possible, the dye demonstrated a remarkable degree of photoinstability, so that the image faded very rapidly. This paper describes a technique in which the use of Hoechst 33258 is combined with Giemsa staining (fluorescent plus

Giemsa or FPG) to make permanent Giemsa-stained cytological preparations of differentially labelled chromatids.

Chinese hamster ovary (CHO) cells were cultured in McCoy's 5A medium supplemented with 13% foetal calf serum. Exponentially growing cells were treated with BrdU (final concentration 10 μm) for 24 h during which time two rounds of replication occurred.

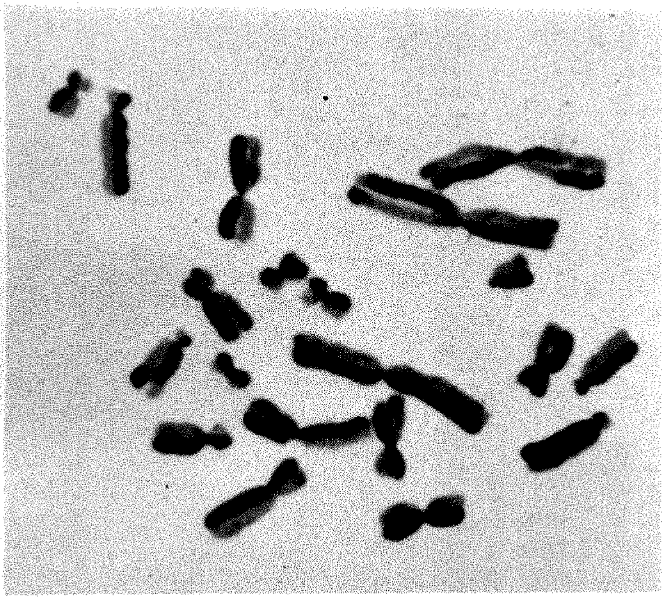

Fig. 2 Cell stained with Hoechst 33258 and then with Giemsa.

All cultures containing BrdU were kept in the dark to minimise the numbers of sister chromatid exchanges caused by the photolysis of BrdU containing DNA[3]. Colcemid (final concentration 2×10^{-7} M) was then added for 2 h and the mitotic cells collected by shaking. The cells were treated for 8 min with 0.075 M KCl to spread the chromosomes and then fixed in methanol acetic acid (3:1).

Drops of cells in fixative were placed on clean microslides and allowed to dry. The slides were then stained in Hoechst 33258 (0.5 μg ml^{-1} deionised water) for 12 min and rinsed briefly in deionised water. The preparations were mounted in water and the cover slip ringed with Holdtite rubber cement to prevent evaporation. Sister chromatids now fluoresced differentially (Fig. 1) as Latt has reported[1].

These same preparations were then allowed to age for 24 h, after which time the coverslips were removed and the slides incubated for 2 h at 60° C in either 2×SSC (0.3 M sodium chloride–0.03 M trisodium citrate) or in water. This was then followed by 30 min staining in 3% Giemsa solution (Gurr's R66 *p*H 6.8). If SSC was used G bands could sometimes be seen.

Figure 2 shows a cell after Hoechst 33258 and Giemsa staining. The Giemsa preparation is now permanent, that is does not fade rapidly, and can be studied at leisure with the compound microscope. The chromatid that incorporated BrdU into both strands of the DNA helix fluoresced dimly and now stains weakly with Giemsa whereas the chromatid that incorporated BrdU into only one strand fluoresced brightly and now stains darkly with Giemsa.

Latt[1] has suggested that the difference between the two chromatids is caused by a differential quenching of fluorescence by the BrdU incorporated in either one or two strands of the DNA. Ikushima and Wolff[3], however, have postulated that differences in the binding of protein to BrdU-containing chromatids is the cause of the differential staining with Giemsa. The differential Giemsa stainability observed here of chromatids pretreated with Hoechst 33258 indicates that the difference cannot be attributed simply to quenching of fluorescence.

Table 1 Sister chromatid exchanges (SCE) observed in CHO cells after two rounds of replication in the presence of BrdU

Stain	(No. of SCE)/ (No. of chromosomes)	No. of SCE per chromosome
Hoechst 33258	360/554	0.65±0.034
Hoechst 33258 followed by Giemsa	149/223	0.668±0.055

This differential staining of the two sister chromatids can also be observed if the cells are stained for 5 min with 0.005% acridine orange in Sörensen's buffer at *p*H 6.7, but is only barely seen, if stained with quinacrine. The difference in fluorescence between the two chromatids, however, is not readily distinguished until the cells are exposed to exciting light passed through a BG 12 filter. Only those cells so exposed show a subsequent differential staining of sister chromatids with Giemsa. If, however, too much exciting light falls on the cell and too much fading of the fluorescence occurs, then the subsequent Giemsa staining is very weak. Similarly, if cells stained with Hoechst 33258, which fades very rapidly, are exposed to exciting light they ordinarily do not stain as well with Giemsa as unexposed cells.

The number of SCEs observed when cells are stained with Hoechst 33258, with or without subsequent Giemsa staining, is greater than the number observed after staining in Giemsa alone[3] or after autoradiography[5]. In addition all chromosomes in a cell can be scored whereas after autoradiography only the larger chromosomes are scorable.

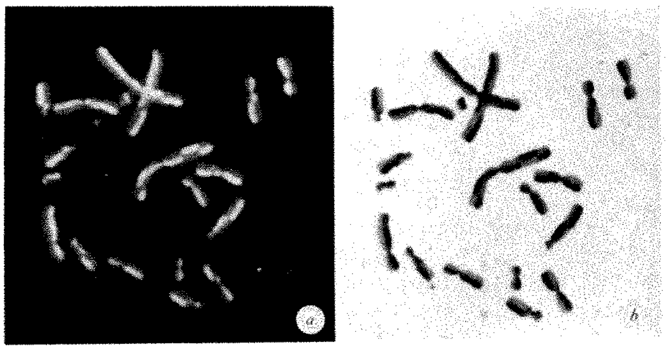

Fig. 3 Cell stained first with Hoechst 33258 (*a*) and subsequently with Giemsa (*b*).

Table 1 presents results of an experiment in which cells were grown in 5 μM BrdU. The frequency of sister chromatid exchanges observed in 33258 plus Giemsa-stained cells was the same as that observed in cells stained with 33258 alone. Furthermore, in Fig. 3 it may be seen that the same exchanges are observable by each technique. The FPG technique does seem to offer some additional resolution, however. We have noticed that when small double exchanges occur near the tips of chromosomes, these can be seen clearly with Giemsa, whereas after fluorescent stain alone, because of flare, both tips often appear to fluoresce and thus mimic isolabelling as seen in autoradiographic preparations.

It therefore seems that the technique presented here has all of the advantages of the fluorescent technique discovered by Latt, but has the additional advantages of producing nonfading permanently stained cells that do not require fluorescence microscopy and photography for their study.

We thank Dr H. Loewe of Farbwerke Hoechst for the Hoechst 33258.

This work was partially performed under the auspices of the United States Atomic Energy Commission. The use of acridine

orange was suggested independently by Professor H. J. Evans and Dr P. Pearson.

Effect of cysteine on the survival of mice with transplanted malignant thymoma

TISSUE collagenase has been detected in inflamed human tissues by Fullmer and Gibson[1], and in some malignant neoplasms by Riley and Peacock[2]. The possible role of tissue collagenase in neoplastic spread has been suggested by Birbeck and Wheatley[3] from an electron microscopic study of the invasion of ascites tumour cells into the abdominal wall of BALB/c mice. They reported that the tumour cells appeared to be actively destroying adjacent normal tissues, which is suggestive of the activity of tissue-destroying enzymes derived from the neoplastic cells. The finding of collagenase activity in human and animal tumours by Riley and Peacock[2], Campbell[4], and Dresden, Heilman and Schmidt[5], prompted a study into the effect that collagenase inhibitors might have on the spread of neoplastic disease. It has been reported by Brown and Weller[3] that corneal ulcerations which inevitably occur following severe alkali burns are due to endogenously produced collagenase and that they can be prevented by topical application of solutions of collagenase inhibitors such as cysteine. The present investigation was designed to test our hypothesis that collagenase produced in malignant neoplasms is a factor in neoplastic invasion and that by inhibiting its activity the arrest of a malignant neoplastic disease could be achieved. The results reported here of initial experiments demonstrate the beneficial effects of cysteine on the survival rates of animals into which malignant thymomas were transplanted.

The malignant thymoma was originally obtained from the Walter and Eliza Hall Institute, Melbourne, where it had been repeatedly transmitted in C57Bl mice. Fresh specimens of thymoma, which have been shown in our laboratories to produce collagenase on *in vitro* cultivation, were cut into 1 mm^3 and then dispersed into single cell suspensions by teasing in sterile 0.15 M NaCl.

Table 1 The effects of cysteine on the survival rates of animals after transplantation of malignant thymomas

Treatment	Mean survival time (d)	Weighted mean survival time (d)
Thymoma alone	31	31
Thymoma + 0.15 M NaCl	34	45
Thymoma + 0.01 M cysteine	37	37
Thymoma + 0.1 M cysteine	37	37
Thymoma + 0.25 M cysteine	65*	98
Thymoma + 0.5 M cysteine	58	86
Thymoma + 1.0 M cysteine	54	65

* Student's *t* test significant at the $P < 0.05$ level.

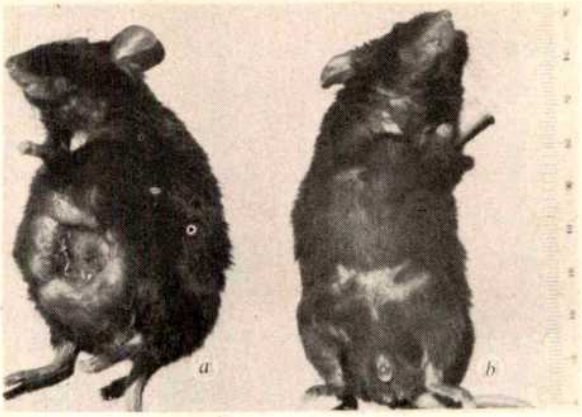

Fig. 1 *a*, C57Bl mouse injected with thymona cells alone died at 38 d. *b*, C57Bl mouse injected with thymoma cells +0.25 M cysteine and killed at 100 d.

Approximately 10^7 viable cells in 0.3 ml of 0.15 M NaCl were infused subcutaneously into the abdominal tissues of male C57Bl mice weighing 20–25 g. The study was designed so that there were seven groups, each with six animals, treated as shown in Table 1. For 8 d, 0.2 ml of the varying concentrations of cysteine; 0.01 M, 0.1 M, 0.25 M, 0.5 M and 1 M; and 0.15 M NaCl as a control, were infused as near as could be determined to the same site as the depot of thymoma cells, commencing 10 d after the initial inoculation of thymoma cells. The macroscopic difference between mice injected with thymoma cells and given no therapy, as illustrated in Fig. 1*a*, or given 0.2 ml of 0.25 M cysteine daily for eight days, as illustrated in Fig. 1*b*, is clearly evident.

The results of the experiment are illustrated in Table 1 and show that 0.25 M cysteine injections significantly ($P<0.05$) prolonged survival time as compared with the saline treated controls and to higher and lower doses of cysteine. The weighted mean (Table 1) takes into account the number of surviving animals at any particular point of time and was calculated according to the method described by Zippin and Armitage[8] using 100 d as the end point of the experiment and highlights in these experiments the difference between control and experimental animals, especially those in which 0.25 M cysteine was administered.

The results of this study suggest that 0.25 M cysteine, introduced locally, is the most effective concentration to inhibit the growth of transplanted malignant thymomas in C57Bl mice.

If the effect of the cysteine is due to its collagenase inhibiting effect described in the literature by Slansky and Gnadinger[9] and Brown and Weller[10], and if the limitations of tumour growth in the described experiments was due to this effect, an important area of investigation is suggested because of the known ability that some malignant neoplasms have of producing tissue collagenase.

Occurrence of lead in tuna

AT a recent national conference in the United States on baseline studies of pollutants in the marine environment[1] serious doubts were raised about the validity of most published measurements of lead concentrations in seawater and in marine organisms Available data for foods and other plant and animal tissues are also implicated because they may contain similar concentrations of lead

It was recommended at the baseline meeting that a workshop be established to carry out interlaboratory analyses of lead in seawater The workshop, sponsored by the National Science Foundation Office for the International Decade of Ocean Exploration (IDOE), was initiated in the autumn of 1972 Samples of seawater standardised at one university by isotope dilution were circulated among participating oceanographic laboratories at seven universities in the United States and at one ministry in the United Kingdom None of the participants was aware of the standardised value until all results had been reported Results of the workshop confirmed suspicions that not one oceanographic laboratory of superior status could, as of September 1973, collect and analyse lead in coastal surface seawater by atomic absorption or anodic stripping voltammetry techniques and report reliable values[2,3] It seems that most published measurements of lead in seawater may be erroneously high by factors of 10 to 100

We have now determined lead concentrations in tuna fish by a reliable analytical technique The observed lead concentrations in muscle are four orders of magnitude lower than those in epidermis Both values lie so far away from generally accepted levels of lead in tissues that analysts may find it difficult to recognise that such lead concentrations actually exist These new findings strongly suggest, as in the case of seawater, that recent studies of the hazards of lead pollution may be misleading if they are based on analyses of plant and animal tissues determined by routine analytical methods carried out without the use of clean-laboratory techniques and without the necessary sensitivity and accuracy

The lead in tuna data are presented here as frames of reference for investigators applying atomic absorption or potentiometric analytical methods to studies of lead in plant and animal tissues

Our data were determined in two laboratories by stable isotope dilution using themal ionisation source high resolution mass spectrometers and special clean-laboratory chemical techniques[2,4] We analysed five types of samples (i) tuna muscle uncontaminated with lead by handling, and containing such small concentrations (~0 0003 p p m wet) that they must be determined with special care, (ii) tuna epidermis, where lead is found concentrated to levels (~2 p p m wet) that are poisonous to humans, (iii) tuna scales and dermis, which contain much less lead than epidermis, (iv) commercial canned tuna muscle, which is contaminated with industrial lead by a factor of 1,000 above levels in living tuna, and (v) a tuna muscle interlaboratory reference that could not be analysed properly by investigators using atomic absorption and anodic stripping techniques in oceanographic laboratories because it did not contain sufficient lead (~0 4 p p m dry), even though it had been contaminated with industrial lead by a factor of 400 above levels in living tuna during preparation by a commercial food manufacturer

Frozen tuna were obtained from IDOE The fish were thawed at 4° C for 24 h, and then exposed to room temperature for 1 h, leaving them still partially frozen and suitable for dissection Clean-room procedures were used to prevent industrial lead contamination, but additional precautions had to be taken to minimise transfer of mucosal slime containing large amounts of lead to interior tissues during dissection

Water was removed from tissues either by heating to 110° C or by vacuum desiccation Values for water contents are approximate because of dehydration and plasma losses between the times when the fish were caught and the thawed tissues were weighed Three methods for decomposing tissue for analysis were used in two laboratories muffle furnace oxidation of 15–40 g wet tissue samples was used at the Scripps Institution of Oceanography, and either low temperature ashing with an excited ozygen plasma or wet acid oxidation of 0 5–4 g wet tissue samples were used at the California Institute of Technology Weighed amounts of lead isotope tracer were homogenised with the lead in the samples during digestion and oxidation, the lead isotope mixtures were isolated by ion-exchange and solvent extraction, and were then analysed in a mass spectrometer The amounts of lead in the samples were calculated from the observed ratios of $^{207}\mathrm{Pb}_{\mathrm{sample}}$ to $^{208}\mathrm{Pb}_{\mathrm{tracer}}$ and the weights of tracer Concentrations were calculated from sample weights

Results for tuna analyses are listed in Table 1 Observed lead concentrations in tuna muscle were so small there was

Table 1 Lead in tuna

Sample Type	Tissue	p p m Pb (wet)	wt % H_2O
8 kg Yellowfin (*Neothunnus macropterus*)	Pectoral fin	5 3	42
8 kg Skipjack (*Katsuwanus pelamis*)	Pectoral fin	4 1	38
7 kg Albacore (*Thunnus alalunga*)	Pectoral fin	0 45	32
(oxidise in excited oxygen plasma)	Epidermis	1 7	67
	Epidermis	1 4	67

concern whether proper mixing of tracer and sample lead isotopes had been achieved. Results obtained by hot HNO_3–$HClO_4$ decomposition at atmospheric pressure were checked by carrying out parallel acid decompositions in Teflon bombs at 180° C and at very high pressures. No significant differences in lead concentrations were observed between the two methods, so we think that proper isotopic equilibration had been achieved at ordinary temperatures and pressures. It seems likely that fresh tuna muscle, uncontaminated by handling, contains about 0.0003 p.p.m. Pb. This contrasts with the very high concentrations of lead in epidermis, which are about 2 p.p.m. in wet tissue. Humans are poisoned if they ingest food containing several p.p.m. Pb for a prolonged period.

It is doubtful that this excessive epidermal lead is an artefact derived from fishing operations because, as shown in Table 1, we have found similar concentrations in whole pectoral fins from different tuna obtained under various circumstances. On a mass balance basis, the lead content of fish fins is determined almost entirely by the concentration of lead in epidermis. The mucin secreted by the mucous cells of the epidermis contains a glycoprotein which reacts with water to form mucous slime. It is likely that strong heavy metal complexing sites in these proteins withdraw lead from seawater and incorporate it into the slime. Our samples of epidermis included the slime coating, and we believe that most of the lead in tuna epidermis is located in epidermal slime. Coombs *et al.*[5] have shown that Ca and Zn are probably concentrated from seawater into epithelial mucus.

Muscle contains quite small concentrations of metabolised lead, probably because of biochemical exclusion mechanisms in the gut membrane. As Table 1 shows, mucus on epithelial tissues in gill filaments do not contain high concentrations of lead, so that it does not seem likely that much lead is adsorbed by gill mucus from seawater and metabolised into fish muscle from gills. As shown in Table 1, for tissues immediately underlying the epidermis, lead concentrations in scales were 1/26th of that in epidermis, while lead in dermis was 1/150th of that in epidermis, but these values may be erroneously high because of cross contamination from mucosal slime during dissection. It seems unlikely that much lead passes through the skin barrier from seawater.

Measured lead concentrations in several sample of commercial canned tuna are listed in Table 1. There is a considerable range in values, one being clearly dangerous to human health. The levels of lead in canned tuna available for human consumption are about 1,000 times above lead levels existing in living tuna. The following evidence shows that this difference in lead levels is common, and is due to contamination by industrial lead.

An interlaboratory reference made of selected high grade fillets of muscle from albacore was prepared by the US National Bureau of Standards (US NBS). The frozen meat fillets were shipped to a commercial food processor, where they were dehydrated, ground, and mixed. Aliquots were placed in polythene bags, and these bags were sealed within lead-soldered vacuum cans for distribution. Lead concentrations determined in this tuna muscle reference are listed in Table 2, together with results obtained for the US NBS bovine liver reference. We consider the bovine liver to be homogeneous in lead on a 0.3 g scale and claim it contains lead within ±2% of the values reported in Table 2 irrespective of the certified value reported by the US NBS (the certified US NBS value is a mean of values determined by different methods, some of which are less reliable than isotope dilution for lead at these concentrations). The considerably wider spread in values obtained for the albacore muscle reference suggests that it is not homogeneous in lead on a 0.3 g scale. The albacore that made up this reference were caught in exactly the same manner, time, and place as the albacore listed in Table 1 (off the southern California coast, July, 1971). The fact that the commercially handled muscle contains 400 times more lead than the same muscle dissected under clean conditions, together with the heterogeneous occurrence of lead in the commercially handled muscle, shows that the tuna muscle reference was contaminated by industrial lead in a commercial food factory by a factor of 400 after it was removed from the sea. This justifies the assertion that canned tuna, representative of that available for human consumption, is contaminated by industrial lead to the extent of about 1,000 times above lead levels in living tuna.

Mucosal slime is not the source of the major part of this lead contamination because it could only raise muscle concentrations by a maximum factor of about 20. Mass balance observations of the distribution of lead in most organs of tuna show that 3% of all the lead in tuna resides at a concentration of about 0.0003 p.p.m. in fresh muscle, while 52% resides in the epidermis at a concentration of about 2 p.p.m. Muscle comprises about 75% of tuna body weight, while epidermis amounts to about one quarter of 1%. The total body burden of lead in albacore tuna is about 0.008 p.p.m.

The following evidence (from ref. 1) suggests that it is difficult, if not impossible, at present for most analysts to determine reliably true values of lead concentrations in marine organisms. The US NBS orchard leaf, bovine liver and tuna references were sent by IDOE for metal analyses to eleven laboratories participating in the IDOE Baseline Studies of Heavy Metals Program. All analysts using atomic absorption and anodic stripping voltammetry techniques were willing to report approximately correct values for the orchard leaf reference, even though it was irrelevant to the problem of analysing lead in marine organisms, because the answer was confidently known and because it contained one hundred and fifty thousand times (44 p.p.m.) more lead than does tuna muscle dissected in a clean laboratory. Not one reported an erroneous value. About half of these analysts refused to report a lead value for the bovine liver reference, while the remainder reported that the lead concentration was less than their ability to measure it (~0.5 p.p.m.). Not one reported an erroneous value. These analysts knew with confidence that lead was about 0.3 p.p.m. in this reference. Most of these analysts refused to report anything regarding lead in the tuna reference. A few reported that lead was less than their measurement limit (~0.5 p.p.m.), while a few reported erroneous lead concentrations that were about an order of magnitude too high. The analysts did not know, before they analysed it, that the lead concentration was 0.4 p.p.m. in the tuna reference.

Since marine organisms can possess soft tissues in close juxtaposition which contain lead concentrations that differ by a factor of 5,000, and since the major mass of live tuna tissue contains such low concentrations of lead that it can be polluted with lead by a factor of 400 before analysis and still contain less lead than most analysts can measure at present, it is clear that a problem exists regarding the evaluation of lead pollution in the marine environment. These difficulties probably extend to the terrestrial environment as well, since it has been recently shown that native field mouse muscle contained only 0.0015 p.p.m. lead in an animal that was known to be 83% polluted with industrial lead, and that mountain freshwater streams contain two orders of magnitude less lead than can be reliably measured by most analysts at present[6].

A fresh outlook regarding lead analyses of biological materials is required. The practical sensitivities and accuracies of atomic absorption and anodic stripping techniques do not appear to be the main sources of difficulty[2]. The real problem appears to be a pervasive lack of understanding of the extent, sources, and ways to eliminate laboratory lead contamination. Substantial improvements could be made if analysts devoted much more care and attention to the evaluation of analytical lead blanks and their reduction and control by the institution of clean-laboratory procedures, together with a realistic scaling up of the quantities of sample lead involved in an analysis so as to substantially exceed laboratory analytical lead blanks.

We thank participants of the IDOE baseline conference for helpful comments, Drs M. Sargent and T. Folsom of SIO for obtaining tuna, and L. T. Silver of CIT for providing Teflon bombs. We thank H. George Snyder and Carrie B. Snyder of SIO for technical help. This work was supported by grants from the IDOE Office of the US National Science Foundation.

Sensitisation of lymphocytes *in vitro* against human melanoma-associated antigens

SENSITISATION of lymphocytes *in vitro* facilitates the study of cellular immune mechanisms under conditions in which the exact input of reactive cells and antigen is controlled. Such systems have been used to generate cytotoxic effector cells against alloantigens[1-3], and more recently against tumour-associated antigens (TAA) in animal models[4,5]. Less work has been done on TAA induction of immune responses using human antigens and effector cells. Golub *et al.*[6] demonstrated *in vitro* sensitisation against antigens present on autochthonous Burkitt lymphoma cells. Since such sensitised cells mediate tumour or allograft rejection reactions *in vivo*[7,8], the *in vitro* 'education' of lymphocytes against TAA is an appealing potential modality for immunotherapy of human cancer. Several preliminary clinical trials have been reported in which 'educated' lymphoid cells were administered to cancer patients[9,10], although the clinical benefits of this procedure remain uncertain. We describe here culture conditions that increase cytotoxic activity of melanoma patients' lymphocytes against melanoma-derived target cell lines.

Dr Hector Sulit of our laboratory established target cell lines from three patients with malignant melanoma and from one patient with osteosarcoma. Control fibroblast lines were established from uninvolved areas of skin or muscle from these patients. The lymphocytes and the cultured cell lines were designated as follows: lymphocytes as 4L, 10L and 14L, cell lines as MLA4, MLA10 and MLA14, fibroblast cultures as MLA4F, MLA10F and MLA14F, and the sarcoma target cell culture as SLA1. The long term breast carcinoma line, BT20, was used in experiments 2 and 4. All other cell lines were used between the fifth and fifteenth passage. All cell lines were free of detectable mycoplasma contamination.

Lymphocytes, usually containing 5–15% monocytes and less than 2% granulocytes, were prepared from peripheral blood samples by Ficoll–Isopaque gradients and were stored in viable condition by slow freezing. For the sensitisation procedure, 2–4 × 10^6 tumour cells were allowed to form a monolayer in a 25 cm^2 Falcon tissue culture flask. Once the cells were firmly attached, the monolayers were treated with 5 $\mu\mathrm{g\,ml}^{-1}$ of mitomycin C and incubated for 18 h. The monolayers were washed and 5 × 10^6 to 9 × 10^6 lymphocytes were added in RPMI 1640 medium supplemented with antibiotics, 15 mM Hepes buffer and 20% pooled normal AB serum. The lymphocytes were sensitised on the monolayers for 5 d, after which they were recovered by washing with warm media. Viable lymphocytes were counted by trypan blue exclusion in a haemocytometer (tumour cells were not viable at this point due to mitomycin). Forty to sixty per cent of the original lymphocytes in culture could usually be recovered. The lymphocytes were washed and resuspended at 1.0 × 10^6 to 1.5 × 10^6 ml^{-1}. Three or more replicate samples of 0.1 ml were tested for ^{3}H–thymidine incorporation and additional aliquots were tested for cytotoxicity. Lymphocyte proliferation was determined by a micro-MLC assay similar to that of Thurman *et al.*[11]. Samples were pulsed with 0.5 μCi of isotope and incubated for 18 h before collection. Cytotoxic activity was assayed by the ^{125}I–iododeoxyuridine (IDU) method of Cohen *et al.*[12]. In this test, lymphocytes are added to ^{125}I–IDU-labelled target cells in Falcon Microtest II plates, usually at an effector: target cell ratio of 100:1 (some experiments involved ratios of 150:1 and 50:1). After 40 h of incubation, the plates were washed to remove lymphocytes and dead target cells. The c.p.m. of isotope remaining in each well indicated the number of target cells surviving the interaction with the lymphocytes.

All experiments had a control culture of lymphocytes cultured for 5 d in the absence of a stimulator cell. Results of the ^{3}H–thymidine incorporation are expressed as a response index (*RI*) calculated by the formula *RI* = Average c.p.m. of sensitised lymphocytes/Average c.p.m. of control lymphocytes.

Results for the cytotoxicity assay are expressed as a cytotoxic index (*CI*) calculated by the formula *CI* = [(average c.p.m. in wells + control lymphocytes) – (Average c.p.m. in wells + sensitised lymphocytes)]/[Average c.p.m. in wells + control lymphocytes].

By calculating the results in this fashion, we could describe only the cytotoxic activity obtained by the sensitisation procedure, rather than the cytotoxicity intrinsic to the melanoma patient's lymphocytes.

In experiment 1, the lymphocytes from melanoma patient 14 were sensitised *in vitro* on autochthonous and allogeneic tumour cells (Table 1). Autochthonous and allogeneic sensitisation produced a small, but significant increase in lymphocyte proliferation. Both sensitised lymphocyte populations displayed increased cytotoxicity against melanoma target cells,

* *P* values were determined by one-tailed Student's *t* test by comparison of control culture (14L) to sensitised culture, ns, not significant at 0 05 level

but not against fibroblasts Autochthonous sensitisation led to greater proliferative and cytotoxic responses than did allogeneic sensitisation This result was not a consistent finding (Table 2) and may be related to the varying antigenicity in the cell lines, because MLA14 has been our strongest stimulator cell

Four further melanoma sensitisation experiments are summarised in Table 2 Lymphocyte samples from all three melanoma patients were sensitised against the autochthonous tumour line as judged by increased cytotoxic activity In each case, the increased cytotoxic activity was only detectable against melanoma target cells, but not against tumour cells of different histological types or against autochthonous fibroblasts The sole exception was some slight 'non specific' cytotoxic activity of the MLA 4-sensitised 4L against the SLA1 target Thus, the cytotoxic activity generated by sensitisation on autochthonous melanoma cells appeared to be specific for a melanoma-associated antigen Sensitisation on allogeneic melanoma cells resulted in even greater cytotoxic activity against either the allogeneic or autochthonous tumour target cells in two of the three experiments Again, no cytotoxic activity against autochthonous fibroblasts was detected Mitomycin-treated stimulator cells alone were not toxic to target cells, nor did they incorporate ^{3}H–thymidine

Lymphocyte proliferation after sensitisation on autochthonous tumour cells was much more variable than was cytotoxicity Only experiments 1 and 3 showed any significant increased incorporation of ^{3}H–thymidine, while none was evident on 10L sensitised on MLA10 (experiments 4 and 5) Autochthonous sensitisation of 10L was less vigorous in cytotoxic response as well The differences among patients may be related to differences in clinical status or perhaps to the kinetics of lymphocyte proliferation Preliminary evidence indicates that the two lymphocyte functions, proliferation and enhancement of cytotoxic activity, may follow different time courses with the peak of proliferative activity preceding the peak of tumour-specific cytotoxic activity This finding is similar to reports from other investigators[13–15] stating that the proliferative and cytotoxic phases of alloantigen sensitisation can be dissociated Details of the time and dose requirements for sensitisation in our system will re reported elsewhere

The antigens to which the lymphocytes were responding appeared to be melanoma-associated because of the pattern of cytotoxic activity and the requirement for melanoma antigens for sensitisation Sensitisation on autochthonous normal fibroblasts (Table 2, experiments 6 and 7) did not result in significant cytotoxicity against any target cell Lymphocytes from patient 4 were sensitised on autochthonous fibroblasts and yielded no significant cytotoxic activity against any target Similar results have been obtained with 10L on MLA10F and 14L on MLA14F Thus, the sensitisation procedure as used in these studies appeared to require the presence of the tumour-associated antigens, and was not simply the result of the cocultivation of lymphocytes with another cell type We are now looking for culture conditions which may allow autosensitisation against normal 'self' antigens expressed on both the fibroblasts and tumour cells[16] Preliminary experiments indicate that sensitisation on allogeneic sarcoma cells does not result in cytotoxicity against the autochthonous melanoma target, again indicating the requirement for the melanoma antigens

The failure of the lymphocytes sensitised on autochthonous cells to kill autochthonous fibroblasts was an especially important control as both these melanoma cells and fibroblasts expressed HL-A antigens in a quantitatively similar fashion (R Reisefeld, personal communication) Both cell types were equally, or nearly equally, sensitive to effector cells sensitised against the alloantigens by mixed lymphocyte culture (MLC)

* *P*<0 05 by Student's *t* test when compared with control lymphocytes
† *P*<0 005
‡ Allogeneic melanoma target cells were MLA10 in experiments 2 and 3 and 7, MLA4 in experiment 4, and MLA14 in experiment 5 and 6
Allogeneic target cells of different histological types were BT20 breast carcinoma in experiments 2 and 4, and SLA1 sarcoma in experiment 3

(experiments 8 and 9, Table 2) In these experiments, lymphocytes from normal donors D or G were sensitised in MLC with mitomycin-treated lymphocytes from patients 4 or 14 The recovered lymphocytes were then tested for cytotoxic activity against both the melanoma cells and the fibroblasts from the donor of the stimulator lymphocytes It was clear that the fibroblast targets were sensitive to the action of effector cells and were not resistant to lysis

In summary, it is possible to generate a cytotoxic response *in vitro* against antigens that seem to be tumour-associated If such sensitised cells have specific cytotoxic activity *in vivo* as well, they may provide a useful therapeutic agent

B and T-cell stimulatory activities of multiple mitogens from pokeweed

MITOGENS, which stimulate cell division in immunocompetent cells, are being used in the study of control mechanisms in cellular division and differentiation In general mitogens are specific for one major class of cells To stimulate immunocompetent cells[1 2], most soluble plant mitogens such as concanavalin A (con A) and phytohaemagglutinin require the presence of thymus-dependent lymphocytes (T cells) On the other hand, bacterial lipopolysaccharide (LPS) stimulates the B (thymus independent) class of lymphocytes[3] In contrast, extracts of *Phytolacca americana* (pokeweed) are reported to have mitogenic activities directed toward both T and B lymphoid cells[4-7] A study of the pokeweed system may provide further information on the differences and similarities in the mechanisms by which these two classes of lymphoid cells are stimulated

We have isolated and characterised five mitogenic proteins from *Phytolacca americana*[8], designated Pa-1 to Pa-5 They are all mitogenic for murine spleen cells over an unusually wide range of protein concentrations We now report their ability to stimulate mitosis in different populations of murine lymphoid cells A complete set of data for Pa-3 is not included in this study because of the very low yield of this protein

The mitotic responses of the different lymphoid populations were measured by the incorporation of ^{3}H-thymidine into the newly synthesised DNA The cells (4×10^5 per well) were cultured by the micro method in the presence of the mitogen for 48 h They were then pulsed with 1 μCi of ^{3}H-thymidine and collected 18 h later as previously described[8]

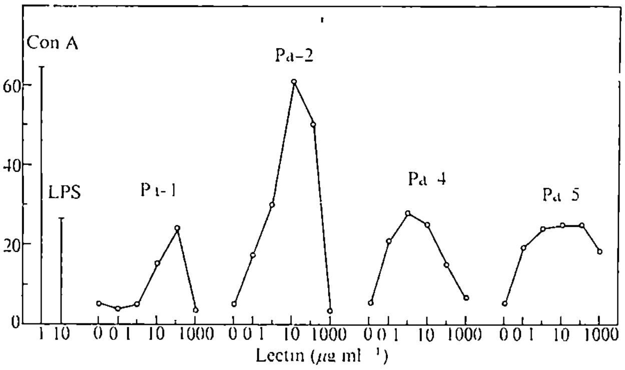

Fig 1 Incorporation of ^{3}H-thymidine by normal spleen cells from BALB/c mice in the presence of the pokeweed mitogens Con A (1 μg ml^{-1}) and LPS (10 μg ml^{-1}) were included as controls for the stimulation of T[1 2] and B[3] cells respectively Results are the geometric mean of triplicate cultures

The dose-response curves of normal spleen cells to these mitogens is presented in Fig 1 Con A, LPS and the four pokeweed mitogens stimulated this mixed population of T and B cells The maximum responses of Pa-1, Pa-4 and Pa-5 were about the same and occurred with concentrations between 1 and 100 μg ml^{-1} Pa-2 induced a considerably higher incorporation, equivalent to that caused by con A, and its maximum occurred at 10 μg ml^{-1} It is unusual for lectins to be mitogenic over such a wide range of concentration For example, con A is mitogenic over a range of a few μg ml^{-1} (refs 4, 9) In contrast, the B cell mitogen, LPS, is active over a wide range of concentration[3]

Figure 2 shows the dose-response curves of thymocytes to these mitogens Incorporation was less than with spleen cells, but the ratios of the maximum stimulated values to the control values were greater The response to LPS was the same as the unstimulated control This is consistent with the absence of B cells and with our observation that less than 1 % of thymocytes stain for immunoglobulin when labelled with fluorescent antibody Con A, the specific T cell mitogen, and all four pokeweed mitogens stimulated these thymocytes Once again, Pa-1, Pa-4 and Pa-5 showed roughly equal activities, about half that of con A, and produced maximal stimulation between about 10 and 100 μg ml^{-1} Pa-2 was the most active mitogen by far, with an activity about three times that of con A These results clearly indicate that the four pokeweed mitogens have stimulatory activities directed toward T cells

To evaluate the mitogenic activities of these pokeweed proteins toward B cells, assays were performed using spleens from TXBM (see legend to Fig 3) mice and spleens from nude mice The dose response curves of TXBM spleen cells to these

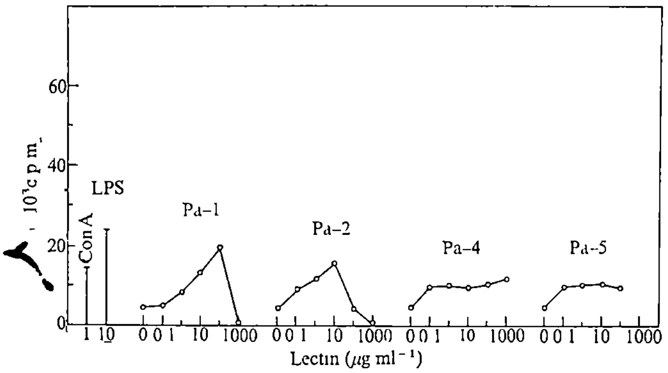

Fig 2 Incorporation of ^{3}H-thymidine by normal thymocytes from BALB/c mice See legend to Fig 1

mitogens are presented in Fig 3 The unstimulated control values were the same as with normal spleen cells (Fig 1), but there was a marked decrease in the response to con A The response of TXBM spleen cells to LPS remained at about the same level as with normal spleen cells Of the four pokeweed mitogens, only the response to Pa-1 remained near the normal spleen cell value The response to Pa-2 decreased to about a quarter, and the responses to Pa-4 and Pa-5 dropped to about one-half of their values with normal spleen cells (Fig 1) The diminished but substantial response to con A may indicate the survival of a population of T cells in these TXBM mice as reported by others The observation that both LPS and Pa-1 were the only mitogens to cause responses similar to those with normal spleen cells suggests that Pa-1 may be mitogenic for B cells as well as T cells The presence of T cells, indicated by the response to con A, makes it impossible to conclude whether or not the response to Pa-1 and the lower responses to Pa-2, Pa-4 and Pa-5 are due to B cell activities on their part or due to residual T cells in the cultures

This ambiguity is resolved by the results with spleen cells from athymic (nude) mice (Fig 4) The unstimulated control values were the same as with normal and TXBM spleen cells (Figs 1 and 3) There was no response, however, to con A, consistent with the absence of T cells, and the B cell response to LPS was increased Of the four pokeweed mitogens, only Pa-1 stimulated these B cells

All these results suggest that in the murine system Pa-1 is mitogenic for both T and B classes of lymphoid cells and that Pa-2, Pa-4 and Pa-5 are mitogenic for only the T class While the trace mitogen, Pa-3, was not included in all these experiments our preliminary results indicate that it has biological properties similar to Pa-2 but is less potent

The differences in the mitogenic specificities of these proteins are directly reflected in their physicochemical properties[8] Pa-1 differs markedly in these properties from the four other pokeweed mitogens Pa-1 has a subunit molecular weight of 22,000, but behaves as a multimer or aggregate during gel filtration in non-dissociating solvents Pa-1 also differs noticeably from the other four proteins in its amino acid composition and has few disulphide bonds In contrast, Pa-2, Pa-3, Pa-4 and Pa-5 are similar to one another in amino acid composition, have many disulphide bonds, and appear to be monomers[8]

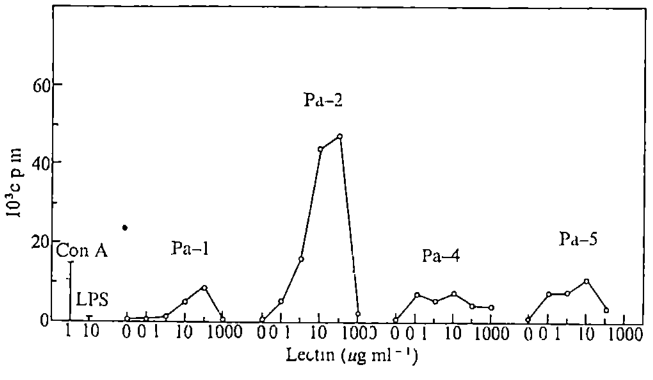

Fig 3 Incorporation of ^{3}H-thymidine by TXBM spleen cells BALB/c mice (4–6 weeks old) were thymectomised, 10 d later they were X irradiated (900 rad) and reconstituted with 7 × 10^6 anti-θ-treated bone marrow cells from littermates The spleens were used 4–6 weeks later See legend to Fig 1

The polymeric state of Pa-1 may be the key to its ability to stimulate B cells It may be that B cell activation requires the interaction of several cell receptors with multimeric stimulants This concept is in accord with the finding that attachment of T cell mitogens such as con A to the bottom of a Petri dish[10] or Agarose beads[6] induces B cell activity Indeed, the attachment of the pokeweed T cell mitogens Pa-2, Pa-4 and Pa-5 to beads induces B cell activity (our unpublished results) The requirement of multiple interactions of the B cell immunoglobulin receptors with antigens[11] and antibodies[12 13] for stimulation has been reported and discussed In a similar way, the multimeric state of Pa-1 and the spatial complex of repeating mitogen molecules attached to beads may react with the B cell to induce mitosis

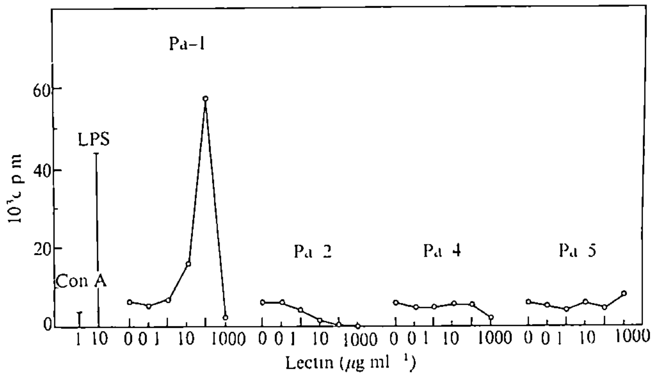

Fig 4 Incorporation of ^{3}H-thymidine by nude spleen cells obtained from athymic mice bearing the *nu/nu* gene on a Swiss genetic background The responses of normal littermates did not differ significantly from the BALB/c spleen cells See legend to Fig 1

matters arising

Liquid drop model of elastin

WE wish to show how the calorimetric observations of Weis-Fogh and Andersen[1] may be interpreted in terms of the classical theory of rubber elasticity It was observed by Weis-Fogh and Andersen that when, for example, 1 33 mcalorie of work was done on a specimen of elastin immersed in water at room temperature, the heat evolved was 5 53 mcalorie according to the theory of rubber elasticity the heat evolved should be close to 1 33 mcalorie This experiment and others of a similar nature with water–ethanol solutions as solvent lead Weis-Fogh and Andersen to reject the classical theory[2] which they replaced by a two-phase model, the liquid-drop elastomer

In approaching this anomaly we formulated the working hypothesis that the apparent conflict between the theory of rubber elasticity and the calorimetric experiments was due to the erroneous assumption that heat change due to the stress-induced absorption of solvent was negligible If a specimen is immersed in a permeating solvent and elongated then it is to be expected that solvent will diffuse into the specimen so that the heat liberated will depend on the magnitude of the differential heat of dilution, $\overline{\Delta H}$ (ref 3)

The most striking observation of Weis-Fogh and Andersen[1] is the systematic decrease in heat release for the elastin–water/ethanol system as the ethanol content of the solvent increases from 0 to 50% At 20% ethanol the heat release equals the work done, in agreement with the theory of rubber elasticity This can be explained in one way only, if our working hypothesis be correct At 20% ethanol $\overline{\Delta H}$ must be zero below 20% ethanol $\overline{\Delta H}$ must be negative and above 20% ethanol it must be positive

In order to determine the magnitude of $\overline{\Delta H}$ it is necessary to determine three partial derivatives[3],

$$\overline{\Delta H} = -T\frac{(\partial f/\partial N)_{PLT}(\partial N/\partial T)_{PLe}}{(\partial N/\partial L)_{PTe}} \quad (1)$$

in which f is force, P pressure, L length, T temperature and e signifies that the specimen is in equilibrium with a reservoir of diluent from which it has absorbed N mol Of the three partial derivatives only one, $(\partial N/\partial T)_{PLe}$ can be measured easily Both $(\partial f/\partial N)_{PLT}$ and $(\partial N/\partial L)_{PTe}$ can be measured but with greater difficulty Since we required only the sign of $\overline{\Delta H}$ we measured $(\partial N/\partial T)_{PLe}$ and assumed $(\partial f/\partial N)_{PLT}$ to be negative and $(\partial N/\partial L)_{PTe}$ positive This assumption is based on sound *a priori* arguments (the opposite assumption would be extremely rash) and is in accord with observation, for instance Abe and Prins[3] for the system water–polyvinyl alcohol It follows then that $\overline{\Delta H}$ will have the same sign as $(\partial N/\partial T)_{PLe}$

Measurements of $(\partial N/\partial T)_{PLe}$ on purified pig aorta at temperatures between 0° and 50° C, have shown that at 20% ethanol $(\partial N/\partial T)_{PLe} = 0$ Below 20% ethanol $(\partial N/\partial T)_{PLe}$ is negative and above it is positive Thus $\overline{\Delta H} = 0$ at 20% ethanol and at this composition the system behaves as a classical elastomer in the calorimetric experiments Full details of this work will be published in due course

The Gibbs Fracture Zone

I WISH to comment on the idea that the Gibbs Fracture Zone may be a westward projection of the Hercynian front into North America Cherkis *et al*[1] have argued in favour of a correlation between the Gibbs Fracture Zone and the late Palaeozoic Hercynian orogenic front

Geophysical evidence[2] indicates that the Gibbs Fracture Zone extends from the Newfoundland continental margin near 52°N 47 5°W to a point west of Ireland, near 52 25°N 16°W Off Newfoundland the fracture zone seems to be associated with a 200 km sinistral offset of the continental edge[3]

If Wilson's[4] theory for the propagation of oceanic fracture zones from old lines of weakness in a formerly contiguous continental crust is applicable here, then an equivalent offset should be present in the European margin Such an offset has not, as yet, been found It is clear that one does not exist in the western margin of Porcupine Bank as implied by the argument of Cherkis *et al*[1] A possible site is near the mouth of Rockall Trough, but the shape of the continent–ocean boundary in this region is not well known

Despite this lack of knowledge about the eastern end of the Gibbs Fracture Zone, it is instructive to follow Wilson's theory and see which predrift continental lineament aligns best with it To do this, I have drawn Palaeozoic structural features of Newfoundland and the British Isles on a new reconstruction of the North Atlantic continents (Fig 1) This reconstruction is more consistent with current knowlege of the structure of the Atlantic Ocean basin than is the reconstruction of Bullard *et al*[5] which was apparently used by Cherkis *et al*, after Hurley The trends of the structures in Ireland are taken from Kennedy *et al*[6] The westward projection of the Hercynian front has not, to my knowledge, been defined by geophysical work, but in the Celtic Sea to the south, a west-south-west Hercynian trend may exist[7] It is therefore possible that the front trends west-south-west In the case of the Caledonoid lineaments there is some

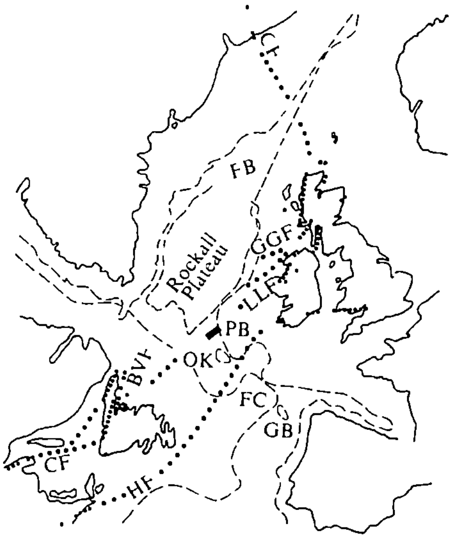

Fig. 1 A reconstruction of the North Atlantic continents (from Scrutton, R A, unpublished) showing Palaeozoic structural lineaments Closely dotted lines, well known trends, widely dotted lines, less well known or conjectural, solid rectangle, the position in which the Gibbs Fracture Zone developed during North Atlantic opening, FB, Faeroes Bank, PB, Porcupine Bank, OK, Orphan Knoll, FC, Flemish Cap, GB, Galicia Bank, CF, Caledonian Front, HF, Hercynian Front, GGF, Great Glen Fault system, LLF, Leck-Leannan Fault, BVF, Baie Verte Fold

magnetic evidence for a general westerly projection towards the outer edge of Porcupine Bank[8] Clearly, correlation of the Gibbs Fracture Zone with any of these structural trends, in particular the Hercynian front, is tenuous

Trends in and around Newfoundland are taken from refs 3 and 6 At present, there is no evidence from Newfoundland of any thrust that can be considered as the equivalent of the Hercynian thrust front of New Brunswick and the British Isles The magnetic anomaly lineations, which Cherkis *et al* suggest indicate the Hercynian Front, in fact overlie a zone of mafic and ultramafic intrusions of Caledonian age[9] and parallel the Caledonoid Hermitage Flexure The Hercynian Front is therefore taken south of Newfoundland to meet the continental edge between Orphan Knoll and Flemish Cap The Caledonian structural trends apparently continue north-eastwards from Newfoundland to the continental edge near the Gibbs Fracture Zone[3], it could be one of these rather than the Hercynian Front that best correlates with the fracture zone

DRS CHERKIS, FLEMING, and MASSINGILL REPLY Scrutton's argument that no offset has been found to link the Gibbs Fracture Zone to the European continent is certainly valid Likewise, his proposed site for the existence of the offset "near the mouth of Rockall Trough" deserves attention We did not, however, suggest[1] that the Gibbs Fracture Zone is represented by the Hercynian Front, but rather that the Hercynian Front provided the zone of weakness in the Proto-Atlantic Ocean, along which a transform fault evolved on the Mid-Atlantic Ridge after the Atlantic [re]opened

Using seismic profiling we have determined that the Gibbs Fracture Zone can be traced to 16°W At that point, the relative proximity of the Porcupine Bank means that the fracture zone cannot turn northward into Rockall Trough The lineation trend of the Hercynian Front in southern Ireland cannot be ignored Projecting this trend across the Porcupine Bank from the Irish coast to the Gibbs Fracture Zone (admittedly, a 180-mile gap) the match is too perfect to be mere coincidence Gray and Stacey[2] found gravity complexities over the Porcupine Bank and Bight that show that positive free-air anomalies terminate abruptly along the projected frontal line Vogt and Avery (Fig 16 of ref 3) showed that negative magnetic anomalies occur along the projected frontal line, interrupting the north–south lineations

Regarding the North American link, Grant[4] showed the Gibbs Fracture Zone coming into the continental margin, and crossing a fault plane We projected the fracture zone through the fault plane and through central Newfoundland, *en echelon* with, or coinciding with, the Caledonian Front An alternative suggestion is that the fault plane may include a strike-slip line, offsetting the Gibbs Fracture Zone to the south through Flemish Pass, and then continuing its easterly course through Nova Scotia and New Brunswick Unfortunately, magnetic measurements do not confirm this, they indicate a more northerly pattern than Scrutton implies from his Fig 1, that is, across Cabot Strait, rather than toward Chedabucto Bay and Nova Scotia Furthermore, Rast and Grant's[5] observations of Hercynian structures in New Brunswick seem to confirm the magnetic trend

The answers to these questions can be solved only with more detailed geophysical studies of the areas

External origin for lunar rilled craters and the mare basins

FLAT-FLOORED craters on the periphery of the lunar maria often contain rilles Because of their location, Whitford-Stark[1] has proposed that these craters are of internal origin and that the mare basins also must be so The assumption that "rilles in all internally rilled craters formed at about the same time as the crater floor" is central to Whitford-Stark's theory Yet, Repsold, Vasco da Gama R, and other ancient, broken craters contain sharp rilles, which often cut mare albedo floors The presence of mare material (lava) on the floors of ancient pre-Imbrian craters shows that the floors, and therefore the rilles, formed after the craters

Quantative support for partial flooding of rilled craters by lava comes from Whitford-Stark's depth–diameter diagram which illustrates that the majority of rilled craters are shallower than normal 'eumorphic' craters Additional evidence of lava fill is provided by his observation that the floors of rilled craters generally have a lower crater density than the floors of non-rilled craters of the same stratigraphical age Thus, the difference between rilled and non-rilled craters need not result from different origins, but rather, may depend upon whether they have been flooded by lava Similarly, the wide scatter of depths of craters of Imbrian age may have resulted from variable depths of lava fill In this context it may be noteworthy that nearly 50% of the craters plotted on Whitford-Stark's depth–diameter diagram are of Imbrian age, that is to say that the craters were formed when magma was abundantly available

There is an alternative to the hypothesis of internal origin for rilled craters Mare basins resulting from gigantic impacts[2] profoundly fractured the lunar crust, creating conduits to the surface for magmas which were extruded approximately 200 to 800 Myr later[3] Craters, predominently of impact origin (ref 4, and Wood, C A, unpublished), that formed near the basins were often flooded by magma rising up basin fractures Rilles could then form, as Whitford-Stark suggested, by contraction of cooling lava ponded within the craters, or by the fracturing of tholoid domes Rilled craters could also form along other zones of structural weakness—such as the Rheita valley[1]—which would provide fractures for magma ascent Thus, although the formation of rilles within craters is a volcanic process, the craters themselves, and the basin fractures, most likely result from impact

Neurones or semiconductors?

On Machine Intelligence By Donald Michie Pp xi+199 (Edinburgh University Edinburgh, April 1974) £2 50

THIS book is a collection of "semi-popular essays written over the past ten years or so" The author's criterion for inclusion is stated with candour "If I enjoyed writing the essay in the first place, and if now I enjoy re-reading it, then I have put it in, otherwise not" The book contains a great deal of repetition—the same tables appear in several different articles, and the same themes occur over and over again with little variation in their treatment Some articles even contain quotations from others

Since the essays were originally intended to be popular, the only work that is described in detail is of a very simple nature such as the author's device for learning to play a good game of noughts and crosses by trial and error Games playing programs receive adequate coverage but there is little attempt to describe the principles behind more recent programs designed to analyse scenes or to understand natural language Readers are told that "powerful new programming aids, such as the PLANNER, QA 4, and CONNIVER languages have come into play", but they are not told what it is about these languages that makes them an advance on previous information processing languages The author has considerable expository skills, and within the limits he sets himself the writing is lively and clear It is a great pity that he has not sat down to write from scratch a systematic introduction to artificial intelligence for the general scientific reader such a book is badly needed and there are few people as well qualified to write it as Donald Michie

The book makes two major claims Michie asserts that developments in artificial intelligence, or as he prefers to call it machine intelligence, will bring about a technological revolution According to "experts", robot chaffeurs and computer psychiatrists will be commercially available by the year 2000 though it will take a further 10 years before automated "general factotums" come off the automated assembly line It may or may not be technically feasible to produce machines that can make as intelligent a use of a wide range of knowledge as do chauffeurs and psychiatrists Leaving this problem aside, there are two arguments, not considered by Michie, which suggest that machine intelligence may not have such a wide role in human affairs by the end of the century

First, in automating a given system, it is often best to redesign it so as to obviate the need for any application of intelligence Automatic pilots do not function in an intelligent way they land planes by flying down a radar beam, and this slavish procedure circumvents the complex perceptual processes used by human pilots It will probably be cheaper and safer to redesign road transport systems in this sort of way, rather than to provide robot chauffeurs that will have to make the same kind of intelligent decisions as a human driver

Second, where automation by the use of unintelligent machines cannot be achieved, as presumably in the case of the psychiatrist, human intelligence is likely to remain for a long time to come a cheaper method of doing the job than the use of large computing systems I once estimated that the cost of a neurone in the brain of a young professionally qualified adult was about 0 00004 new pence This estimate includes the programming costs for the whole system and it is orders of magnitude cheaper than the cost of a Japanese semiconductor The extent to which artificial intelligence makes a contribution to technology depends on cost-effectiveness, and even if the problems of making intelligent systems were solved, it is by no means obvious that they would be the cheapest means of undertaking tasks requiring intelligence

Michie's second claim is that machine intelligence is likely to provide new insights into the working of the human mind, and this assertion is perhaps less disputable Until recently, psychologists did not have a language in which they could couch well formulated theories of how complex information processing tasks are carried out Computer languages provide the appropriate symbolism and the digital computer itself provides a method of rigorously exploring the consequences of a given theory It is perhaps unlikely, however, that programs that simulate the details of the way the brain operates will be written merely by reflecting on the best way in which to program a computer to undertake a particular task It will be necessary also to take into account the experimental evidence on how the brain actually does process information Michie (page 123) asks his readers whether, when parsing a grammatically ambiguous sentence, "you generate the alternative parsings, subsequently to be eliminated by semantic hindsight Of course you don't We can be sure that we do not do this consciously" But recent psychological evidence indicates that at least in some cases we do generate different interpretations at an unconscious level Only one of these may be selected as a result of semantic disambiguation, and it is only the results of such selection that appear in consciousness The study of the mind from an armchair or a programmer's stool contains dangers of this sort, and it is likely that our understanding will be best forwarded by using the computer as a tool with which to construct and to explore theories, at the same time being careful to base the theories on the best experimental evidence available

N S SUTHERLAND

Teaching the heart

Universities Between Two Worlds By Roy W Niblett Pp viii+179 (University of London London, June 1974) £2 85

ARE we, in the Western world, at a watershed of civilisation, "between two worlds"? Professor Niblett believes that we are, and in this book he spells out what he regards as some of the consequences for universities His theme is familiar the growing disenchantment with the emphasis which universities put upon the cognitive, the rational, the analytical approach to phenomena, the insufficiency of this approach to solve the problems of contemporary society, the need, therefore, for universities to provide experience in "sensate culture", to ask questions about ends as well as means, about values as well as facts, to engage (as Niblett puts it) the "individual mind and heart" in the process of higher education It is a plea to university teachers to impart not just knowledge, but wisdom, to their pupils

That Western man is deficient in wisdom and has, if anything, a surfeit of knowledge (much of it useless) is a proposition few would challenge But that universities are the institutions to remedy this deficiency is another matter Niblett believes that they are, and the value of this thoughtful essay is that the reader must decide whether he accepts Niblett's belief or not

His diagnosis of higher education (he has in mind particularly Britain and America) is that it has tried to break away from the pursuit of narrow specialisms, and has failed Liberal studies, joint honours schools, the redrawn 'map of learning' in the new universities, the Harvard red book on general education all have led to disappointment The causes of disappointment include the inflexibility of discipline-oriented teachers, the persistence of competition in examinations, the lure of professionalism, and pedantry among those who teach the humanities "The choice before the humanities is clear either to pretend to be sciences or to acknowledge without shame the experiencing and imaginative elements within any essential study of them " The word 'feelings' occurs often throughout the book, feelings must be recognised, identified, and incorporated into the academic experience

In his courteous and gentle way, Niblett makes some highly controversial assumptions which some of his readers will challenge First, are we really between two worlds? Is this a watershed similar to the great divide between Galileo and the Schoolmen? Many will question this assumption The scientific approach to nature and to man still succeeds superbly in answering scientific questions, it was never designed to answer other sorts of questions Nor are the other sorts of questions novel, needing new techniques As Niblett himself suggests, you do not "decide to love or trust another human being", so case studies in decision making (a popular form of broader education) do not embrace some of the essential human activities But societies have been concerned for millenia with love, trust, and the whole spectrum of moral values

The burden of Niblett's message is precisely the same as Walter Moberly's, written 25 years ago, and it is a response to the same dilemma The only difference is that in 1949 only dons appreciated the dilemma, today students appreciate it too The dilemma is that universities, in common with madrasas in the muslim world and the ancient Buddhist seminaries of India, have for six sevenths of their history been religious institutions, resting on a foundation of faith, commanding a consensus of values It is only since University College, London, was founded that the formal link between faith, morals, and learning was broken Both Niblett and Moberly believe (though they approach the issue from different directions) that universities should adapt themselves to the consequences of this severance But some readers will ask should they? There surely is a case for differentiation of functions among institutions When the church tried to meddle with science in the 19th century, it was religion, and the sensate culture associated with it which suffered If the universities now try overtly to meddle in the non-cognitive sphere, important as it undoubtedly is, is there not a risk that they will prove incompetent (professors are no longer elected on grounds of virtue or wisdom) and that the university's unique function, to teach the art of rational analysis, will be eroded? If the purpose of the book is to stimulate reflections of this kind, it deserves to be widely read

Niblett himself admits that there is no clear way to teach the sensate culture And indeed some of us who are close to students doubt whether they are as impoverished in non-cognitive experience as he supposes Not enough of them find, as he puts it, "a sense of values in an age of facts" This has not been my experience I find more concern with moral issues, more compassion, and a livelier (if puzzling) commitment to the sensate culture among today's students than among those who were students when Niblett and I were undergraduates I wonder whether (perhaps) they are getting on quite well, thank you, without our help It is a humiliating admission for an academic to make after a lifetime in universities, but I, for one, would admit that despite all our anxious design of curricula and the student environment, most students get from universities not what we plan to give them but what they come to find Over their morals and personal values we cannot do in three years what home, school, and church may have left undone in the previous 18 years Over their adolescent intellects we can do a lot we can open the doors of the mind

Eric Ashby

Extended scope of NMR

NMR of Paramagnetic Molecules Principles and Applications Edited by G N La Mar, W DeW Horrocks, jun , and R H Holm Pp xv+678 (Academic New York and London, December 1973) \$42, £19 25

Although the effects of small amounts of paramagnetic impurities on nuclear resonances of diamagnetic solid or liquid samples were discussed in some of the earliest work on NMR in bulk matter, it was not until 1956 that direct observations on the paramagnetic crystal, MnF_2, by Shulman and Jaccarino were described and interpreted in terms of chemical bonding Since then it has been realised that although the powerful electronic magnetic moments in paramagnetic substances induce strong nuclear relaxation in neighbouring atoms in the same compound, the effect is often none the less weak enough to allow a great deal of the information in the nuclear resonance spectrum to be obtained The modulation of the nuclear resonance by the paramagnetic moment turns out to be of the greatest importance, and measurements of NMR spectra of paramagnetic substances have extended in a most dramatic way the application of NMR to such diverse fields on the physical chemistry of transition metal complexes and the structures of enzymes

Professors La Mar, Horrocks and Holm have succeeded in persuading an authoritative group of authors to set out the theoretical bases of this important area of research and to review the range of applications which have been explored up to 1973

The first three chapters by Jesson, Swift and by La Mar, comprising about one fifth of the book, give an excellent account of the basic theory and are so clear and well set out that they will be of great value to the beginner who already has an understanding of the principles of magnetic resonance, as well as to the researcher needing a convenient summary The chapter by Jesson sets out the theory of the paramagnetic shift, including a very clear account of the Kurland and McGarvey general treatment This is illustrated by some examples and at the end of the chapter there is an appendix on density matrix theory The second chapter by Swift deals with the effect of the paramagnetic moment on relaxation times This is a very good and concise exposition of the various effects needed to interpret the spectra In the third chapter the theory of the delocalisation of spin density is set out in detail

The remaining thirteen chapters review the applications of these principles to an extraordinary range of chemical studies including spin distribution over organic and organometallic compounds, stereochemistry, kinetics of intramolecular rearrangements, equilibria in solution, and applications to biochemical studies These review chapters present illustrative examples which are worked out in some detail, for an understanding of which a careful study of the first three chapters of the book is a good preparation

This is a most valuable book for the many research workers who could make good use of measurements of this kind, though the sheer range and versatility of the problems described will be daunting to a beginner

R E Richards

Peripatetic naturalist

Linnaeus's Öland and Gotland Journey 1741 Translated from the Swedish edition of 1745 by Marie Åsberg and William T Stearn. Pp viii+220 (Academic: London, Linnean Society of London, February 1974.) £6, $17.50.

In 1741, at the age of thirty-four, Carl Linnaeus was already an eminent naturalist and professor of medicine when he set out to survey the natural resources of the Baltic islands of Oland and Gotland. Taking with him six male companions, he travelled at the behest of the Swedish Parliament, which was intent on economic recovery through the exploitation of domestic raw materials. While familiarising himself with the natural history of the islands, Linnaeus was instructed particularly to look for plants suitable for making dyes, or with pharmacognostic value, and for clay or earth suitable for the production of such things as pottery and pipes. He was also required to keep an accurate diary, which was pubished in 1745 and is now made accessible to English speaking readers by Drs Åsberg and Stearn in their enjoyable translation. The style is that of daily field notes that have been tidied up grammatically, but not turned into a continuous narrative. Although not competing as bedtime reading with the picaresque novels of the period, the diary provides some interesting insights into the observational methods and common sense attitudes of the man who is remembered chiefly for giving the world the binomial system of nomenclature for plants and animals.

The members of the expedition left Stockholm on May 15, and, travelling on horseback, reached the coastal town of Kalmar on May 27. After waiting in vain for the weather to improve, they embarked on the ferry for the three-mile passage to Oland, hastened by two cases of spotted fever in the house where they had stayed. By July 27, when they returned to the mainland, they had traversed much of this narrow island, as well as Gotland, on which they spent thirty-four days. On the latter, the diary disdainfully records, there were no persons of standing except for two judges and a captain.

Linnaeus was well pleased with the journey. He recorded a hundred plants then unknown in Sweden, including several with pharmaceutical uses, such as *Ruta muraria* (now known as *Asplenium ruta-muraria*) which previously had been imported.

Finding woad (*Isatis*) growing in abundance on Klasen, a small island near Gotland, he recommended that it would be worthwhile to sow the species more extensively. In other places the extraction of dye from plants was recorded assiduously for the parliament. Usually leaves or roots were boiled together with yarn, which was subsequently treated with an alkaline concoction to fasten the colour.

By such a procedure, yellow dye was obtained from burmarigold (*Bidens tripartita*) and juniper moss (*Cetraria juniperina*), brownish red from *Origanum vulgare*, a lemon colour from apple bark and dark brown from soot. But no use had been found for the red colour of the rotting seaweed that covered some of the shores of Oland, and "gave off such a stench, as if ten horses had been roasted in the sun". Seaweed, however, was put to good use in other places, as manure and for thatching roofs.

Local remedies were found for all manner of ills. These included the moss *Sphagnum palustre* which was cooked in beer and laid on swollen legs, grasshoppers that spat out a black liquid, causing warts to disappear, the root of *Valeriana officinalis* which was used for hysteria (Linnaeus failed to record how), and *Solanum officinarum*, ground up with spiders web and rancid pork to treat whitlows.

While the expedition was at Forosund on Gotland the farmers left their fields and fences to indulge in feasting and dancing. Here Linnaeus drew a picture of a seamless bagpipe made from a seal's stomach, with the modulator placed in the pylorus and the base inserted into the oesophagus. Seals (*Phoca vitulina*) served other purposes in the economy of Gotland and there are several accounts of hunting methods. The beasts were caught in nets and either harpooned or bludgeoned on their very sensitive noses. Seal lard was sold, the meat was eaten, and the fresh fat could be used instead of butter for frying pancakes. Porpoises were sometimes caught in the nets accidentally, and Linnaeus thought it quite remarkable that nobody had developed the art of trapping them, for their lard was as useful as that from seals.

Interspersed among meticulous accounts of this sort, and descriptions of fences, corn fields, runic stones, flora and fauna, Linnaeus provided notes on local superstitions. This he did "more to entertain my reader than for any other reason". On mainland Sweden the rational professor was not impressed by the belief that when a farmer's cow died he could transfer the bad luck to his neighbour's cattle by burying the carcase in the neighbour's field or dung hill. Such beliefs "and infinitely much more of similar rubbish" were dismissed as relics of heathen and popish times. Linnaeus' prescription for the eradication of such things was to instruct future theologians well in natural history and natural philosophy, since nothing served so well to
the contempt o
solved to teach hi
University everyth
them to go into th
instruct their parishio
vantage. This he did, a
besides, as botanists kno
diary shows them an aspect
with which they may not
familiar.

MARY D

Scientists in the world

Towards a Political Sociology *Science*. By Stuart S Blume. Pp xii+288 (Free Press: New York; Collier-Macmillan: London, April 1974.) £4.95.

Like all really good empirical studies in the human sciences, this one is addressed to a theoretical problem. That is, the nature of the scientific community. The author argues that, for sociological analysis, it must be considered as both involved in national political life and also internally differentiated by power relations between elites and others.

In the post-Rothschild epoch of fully industrialised science this thesis is hardly likely to cause outrage among working scientists. But it does represent an important development in the sociology of science. Lest natural scientists dismiss it on that ground they should recall how naive and short-sighted were the dominant assumptions of scientists' own common sense about the social activity of science all through the postwar period.

In the sociology of science, debate is still organised around the ideas of Robert K Merton. We can distinguish three phases of 'Mertonism', a set of received research paradigms much simpler than the contemporary enquiries by Merton himself. At the beginning was the attempt, through the 'four norms' and the 'ethos' of science, to identify the implicit value system of scholarship with that of the most enlightened democracy, political and economic. In the post-war period Mertonism shifted to the motivational machinery by which men in this idealised scientific community are induced to merge self interest with the common good. Recently, more realistic details have been introduced, exhibiting the community as a geronto-aristocracy, and seeing how well this social structure works.

Even this 'late Mertonism' imagines a community of 'pure' science, doing its own praiseworthy thing in a social vacuum. Blume contends that such a model is drastically over-simple. His main thesis is that the élites in science are maintained in power partly by their external connections and that they e their recruits partly by criteria than scientific merit It is then an ely open question, left as such by ne, whether this arrangement is the t possible The reader may, if he shes, draw the further conclusion at the government of science is ripe or political reform

It would be misleading to represent the book as structured tightly around this particular polemical thesis Rather, there is a broad survey, extending into such unaccustomed fields as unionisation and 'politicisation', but everywhere considering science as one institution among many, whose functioning involves 'politics' in every sense of the term Even where Blume deals with topics traditionally considered as 'internal' to the scientific community, as organisations and 'social control', he unromantically invokes relations of status, authority and power as the basic explanatory principles The material on "scientists and government" presents few methodological problems

Oddly enough the concluding chapter on "innovation and society" rings slightly off-true The case study here, fluoridisation, is of great systematic interest for the sociology of knowledge and control, but it is somewhat outside the main trend of the book, if nothing else than because the 'science' involved is medical (which remains peculiarly remote, intellectually and socially, from the central physical sciences) It may be that in spite of his sympathetic treatment of radical science groups, Blume has mised one crucial feature of the present connection between science and the lay public This is the major part played by non-scientists, notably critical journalists, who muckrake establishment technology from the social and environmental points of view Even if their excesses of zeal and haste do occasionally produce errors of fact and method even greater than those of their technically qualified opponents, they are now a permanent part of the scientific scene Their influence on present recruits to science is not to be overlooked

Considering this book as a contribution within the sociology of science, we may see it as opening a new phase, a final liberation from the Mertonian paradigm Being empirical political sociology, it inevitably changes the terms of the debate away from models of a 'scientific community' towards an examination of a quasi-profession that depends on the state and industry for its existence Sociologists of science no longer need to be tough-minded in demythologising 'science', the simple facts of life about this sector of production render myths, models and ethos equally irrelevant

It will be very interesting to see whether there is an effective reaction against this tendency If not, we can mark one of the most important changes in the political sociology of science viewed historically For the ideology of science which (*pace* Blume) has a significant history extending back a couple of centuries, is built into beliefs and practices of many other spheres of activity, the term 'social science' can indicate this An impairment of the functions performed by that ideology, within science as well as externally, will produce new phenomena quite as interesting as any studied in this present excellent survey

J R RAVETZ

First map of the Moon

Thomas Harriot Renaissance Scientist Edited by John W Shirley Pp x+181+4 plates (Clarendon Oxford, Oxford University London, June 1974) £6 50

THIS book consists of seven varied essays, which are based on papers read at a symposium held at the University of Delaware on 5-7 April 1971 The editor explains in his preface why we should take an interest in Thomas Harriot (1560–1621) "Though recognised by his contemporaries as England's most profound mathematician, most imaginative and methodical experimental scientist, and first of all Englishmen to make a telescope and turn it on the heavens, Harriot had not prepared his work for future generations" This neglect of self-advertisement was doubtless produced partly by the superstitions of the age that could pillory an astronomer, and partly by the need to keep as state secrets the new techniques in instrumental navigation, the means by which England might survive economically He did publish, in 1588, his account of a trip with Ralegh to Virginia, and is consequently now known among historians on both sides of the Atlantic as a pioneer, natural historian, ethnographer, and as one who made a systematic study of the Algonquian language But, as a scientist, he is still the Cheshire Cat's grin

It becomes apparent that Harriot knew the sine law of refraction before Snel and Descartes, and was the first man to draw a Moon map with the aid of a telescope His earliest known telescopic observation of the Moon, on July 26, 1609 (OS) at 9 p m , was made nearly three weeks before Galileo presented his telescope to the Venetian Senate, of which instrument Harriot could have had no knowledge whatever Again, he may be given priority in the telescopic observation of sunspots, first recorded on December 8, 1610

The trouble comes when one assesses the significance of Harriot in the history of science As his pupil and friend Sir William Lower wrote on February 6 1610 "yet too great reservedness hath robbed you of those glories it is possible by too much procrastination to be prevented in the honour of some of your rarest inventions and speculations Let your country and friends enjoy the comforts they would have in the true and great honour you would purchase yourself by publishing some of your choice works" In this connection, Dr North, in chapter 7, reminds us of Arago's "règle aux historiens des sciences", which was public utility, implying prompt publication There is no doubt, however, that Harriot contributed to new techniques in navigation and in the training of navigators

The present volume contains Professor Rosen on the intellectual background, Professor Shirley on Harriot's service with Ralegh, Professor Quinn on the Virginian expedition, Dr Pepper's highly technical paper on mathematical navigation, Dr Tanner on associates of Harriot, with a gratuitous attack on Henry Stevens (1819–86) who found Harriot's will, Professor Jacquot on the new natural philosophy, Dr North on Harriot's ten telescopes and the earliest observations made with them These papers show the signs of their symposium origin The same quotation may appear in different essays, and the references at the ends of the chapters (difficult of access here, why not have them in the proper place at the foot of the page?) and modes of citation are not made completely uniform The nine-page bibliography lists the primary and secondary manuscripts, books published around Harriot's time, and modern studies relating directly or tenuously to Harriot The Clarendon Press should have been more careful over consistency in the references (ibid is in italic or roman, journal volume numbers are in arabic or roman), in ensuring that the "selective" index always led to the correct page, that the plate captions were properly positioned, and that type had not slipped

As Professor Shirley explains, the study of the contemporary evidence, household accounts of the Northumberlands, the public records, the Harriot manuscripts, has not been completed This book of essays is, then, an expensive trailer for the main feature still to be shot One can query the value of publishing this collection in book form, thus giving it permanence What is needed first is a detailed description and assessment of the Harriot manuscript material Only when this was been done can his significance be evaluated

G L'E TURNER

Detecting nuclear particles

Nuclear Electronics By P W Nicholson Pp xiv+388 (Wiley London and New York, April 1974) £8 75

THIS book is aimed specifically at physics graduates needing to use nuclear detectors The first two chapters are introductory accounts of the principles involved in detecting nuclear particles and of the basic ideas of pulse circuits, these chapters are provided on the assumption, which unfortunately is probably correct, that most undergraduate courses contain very little on these topics The next three chapters give an account of the general problem of the amplification of nuclear pulses and the methods of minimising the effect of noise This is the most attractive part of the book as the author gives particularly clear explanations of the problems which arise and the methods used to solve them The remaining chapters deal with discrminators, digitising techniques, for both amplitudes and time differences, and various more specialised circuits In these sections it is inevitably more difficult to provide any connected chain of argument but the treatment is still reasonably uniform any theory is given first, the various difficulties and their solution are clearly explained and a well chosen selection of recently published circuits is given as illustration

This is essentially a text book rather than a practical guide Brief accounts are included of the operation of some semiconductor devices, but the whole subject of component characteristics and limitations is omitted and there is hardly any mention of practical 'engineering' problems such as interference, effects of stray capacitances or long-term stability

I think the author has been very successful in carrying out his purpose but unfortunately a detailed theoretical understanding is not sufficient for the experimental physicist, whose problems in practice are of two sorts First, given a large budget, he has to ask whether commercially available equipment will have the necessary performance, this book will certainly help him to understand manufacturers' specifications but considerable skill and experience in electronics is necessary to solve those problems for which equipment is not available Second, and especially for those with inadequate budgets, it is necessary to know how to build circuits with a performance which, though less than 'state of the art', may still be adequate for a particular purpose So it seems a pity that Dr Nicholson, by concentrating on the best published circuits, gives little indication of what may be achieved more simply For example, it would have been worth stressing how easy it is, even for the non-specialist, to use digital integrated circuits in constructing counting equipment

Despite such omissions, this book will be very useful to anybody working with nuclear counting systems I noted only a few errors or misprints and the author is to be particularly commended on the clarity of his explanations and of the diagrams J C BARTON

Counting heads

A Workbook in Demography By Roland Pressat Translated by E Grebenik with C A M Sym Pp 292 (Methuen London, May 1974) £7 90

THE age of the population explosion and its implications for society and for the world's resource base has attracted students in several disciplines to examine demographic problems This interest is catered for by a growing general literature and by regional and case studies, but the techniques and methodology of demography have been generally somewhat neglected Many postgraduate students find a need to provide their own basic training and regret the absence of straightforward, general textbooks that explain not only simply concepts but also the practical mechanism of calculating data from raw statistics, illustrating where relevant the major pitfalls for the unwary Few are as well qualified to undertake this task as Professor Pressat, a mathematician by training, who has done much to define the aims and methods of the quantitative approach to population study He has provided us with just such a textbook as described above, setting up problems, supplying suitable data and offering means of solution and explanation of significance

The "exercises"—for this is truly a workbook—have been selected to present real life situations The examples are spread widely over the confusing variety of situations that confront the beginner and the author brings to them an understandable order and relevance For the more advanced student, he has sought to provide examples close to the situations faced by research workers Not all the exercises are mathematical several depend on descriptive interpretation Nevertheless, using his early training, he makes the mathematics intelligible to those with only modest numeracy Although designed for students in the University of Paris and consequently using substantial amounts of French data, the author has nevertheless selected from a wide range of countries, both "advanced" and "developing", and he has included some most interesting Soviet material

The topics are grouped conceptually, starting with the concept of a population The reader is then taken through the measurement and comparison of mortality and some of the main problems of such difficulties as the misstatement of age The exercises include not only contemporary situations but also the techniques of calculating data for past conditions Anomalies, wherever they occur, are explained at length and in his answers the author makes some interesting comments on contemporary problems For example, the stress of modern urban living may kill the weaker older people who survived infancy through the advances of modern medicine, whereas in earlier times they would have been winnowed by natural selection in childhood Nuptiality, disunion (separation?) and re-marriage are dealt with in a similar manner and are followed by examination of fertility, where material is drawn from North American and African experience and used in comparative studies The final section covers ageing population, infant mortality, birth order and replacement It is a pity there is nothing on migration

Treatment is thorough and wherever necessary basic techniques are explained The student will find the many valuable formulae most useful and the author explains how to use fragmentary and unsatisfactory data by skilful manipulation This is indispensible as a reference book for anybody interested in population

R E H MELLOR

Not so fast

Chemical Kinetics Homogeneous Reactions By N M Emanuel' and D G Knorre Translated from Russian by R Kondor Translation edited by D Slutzkin Pp xii+447 (Wiley New York and Toronto, Israel Program for Scientific Translations Jerusalem, February 1974) £8

THIS is a soundly written book with a broad coverage of topics It is, however, mainly concerned with work up to and including the early transition state era As a succinct example, the work of Michael Polanyi on energy surfaces is described, but not that of his son John Polanyi All this gives the book an oddly out-of-date flavour Short references to flash photolysis, electron paramagnetic resonance and so on indicate the updating efforts of the second Russian edition (Moscow, 1969) but the general effect still remains Honours students may look at the book for background material, chemists generally for the mathematical treatments of the concentration–time curves of various complex reactions But there is nothing here comparable to the general monographs of, say, Kassel or

Hinshelwood—nothing to inspire the research workers in chemical kinetics, to draw young people into the subject, or to give succour to those peris outside paradise, the workers in heterogeneous catalysis This is, I fear, a rather dull book a Moskvich rather than a Lotus Elan D D Eley

Turbulent plasmas

Plasma Astrophysics By S A Kaplan and V N Tsytovich Translated by D ter Haar Pp xiii+302 (International Series of Monographs in Natural Philosophy) (Pergamon Oxford and New York, November 1973) £9 50

This book follows on naturally from *An Introduction to the Theory of Turbulent Plasmas* by Tsytovich, bringing together references to many of the papers published by Russian workers in the last few years In this work the authors are concerned primarily with radiation and particle acceleration by turbulent plasmas in the sun, pulsars, nuclei of galaxies, radio galaxies and quasars The authors restrict their attention to weak turbulence where the energy density of plasma waves is much less than the plasma thermal energy density They assert that strong turbulence decays on a time scale which is short compared with astrophysical times leaving the plasma in a state of weak turbulence Recently discovered 'spicons' in laboratory plasmas with wave energy densities large in comparison with the thermal energy density may eventually cast some doubt on the universal applicability of the weak turbulence assumption to astrophysical plasmas Within the weak turbulence assumption the authors discuss three types of turbulence 'heating turbulence', where the energy of plasma waves is dissipated through electron–ion collisions and Landau damping, 'acceleration plasma turbulence', where the wave energy is lost in accelerating particles, and 'radiation plasma turbulence' where low frequency plasma wave energy is lost by the generation of high frequency electromagnetic waves produced by the interaction of plasma with particles

The book is divided into four chapters· the first reviews, with liberal reference to the literature, laboratory and theoretical developments in plasma turbulence The second chapter deals with sporadic solar emission, for example, how electromagnetic waves may be generated by ion-sound turbulence The third discusses how turbulent processes can lead to observable radiation in for example radio galaxies and quasars, and the book ends with a discussion of pulsar emission

The authors consider that the most important causes of plasma turbulence, at least in a narrow frequency range are beam, ion drift, loss-cone and anisotropy plasma instabilities To these one should probably now add parametric instabilities occurring in the wave zones of pulsars It is not yet clear whether refractive index effects, incurred by requiring a dense plasma to act as a vehicle for the turbulence, will inhibit radiative processes involving relativistic particles The turbulent reactor production of a cosmic-ray ion power low spectrum meets with some difficulty if located in pulsars The authors prefer to have the source in the nucleus of the galaxy, the implication for isotropy is not clear from their arguments

The book is clearly written and the translator is obviously familiar with the scientific content of the work The book is a very important addition to the astrophysicist's library, the new graduate student might however consider reading a more elementary text before attempting it P Stewart

Classifying vegetation

Ordination and Classification of Communities Edited by R H Whittaker. Pp x+738 (Handbook of Vegetation Science, Vol 5) (Junk The Hague, 1973) Dfl 160

A decade ago the production of a volume such as this would not have been possible, but through the agency of the International Society for Plant Geography and Ecology symposia, the different approaches to vegetation, each with its own recondite peculiarities have been interchanged, discussed and dissected But this is only half the story To coax and cajole nineteen eminent practitioners from eight countries to contribute to the tome is no mean feat, and the praise for the commonplace drudgery and exasperating mechanics of coordination of the contributions falls firmly upon the energetic frame of Robert Whittaker There can be no doubt that the dynamic personality of this man and the depth of scientific respect which he commands made the project a viable one, and the patient understanding provided by the publishers helped to ensure a production of the highest quality

The book is divided naturally into three sections—direct gradient analysis, indirect gradient analysis and classification The first section contains five papers, four of which have Whittaker as senior author, and a fifth written by Sobolev and Utekhin of the Soviet Academy of Sciences, Moscow Much of Whittaker's contribution seems to be a new presentation of his earlier works, particularly his 1967 *Biological Review* paper, but as a part of a general overview of methodology, its presence is vital The two Russian authors provide a refreshing interpretation of the much abused Ramensky continuum concept which makes possible a far deeper insight into this approach than has been previously possible

The second section contains typically thorough and informative papers on sample similarity and species correlation by Goodall, factor analysis by Dagnelie and ordination by resemblance matrices contributed by Orloci The methods of comparative ordination evolved by the Wisconsin school some twenty years ago are re-examined by Cottam, Goff and Whittaker and, like the paper on matrix and plexus techniques by McIntosh will win many plaudits for its simplicity and clarity of presentation But pride of place in this section must be given to the invaluable paper of Whittaker and Gauch which provides a realistic and erudite evaluation of ordination techniques using such criteria as efficiency, relative freedom from distortion of sample relationship and computational expenditure

Whittaker is also responsible for two chapters in section 3—one, his familiar enumeration of the bases of vegetation classification and the different traditions which have evolved, the other a short discussion on the nature of dominance types which neatly complements the paper on the physiognomic approach by Beard To many European phytosociologists, chapters 15 to 18 and 20 will prove to be invaluable, if not the highlight of the book They comprise papers written by practitioners from various European countries who are fully conversant with the intricacies of and interpretations to be derived from methods which they themselves have used extensively In this respect, the contributions of Frey, Alexsandrova and Trass and Malmer on the Finnish, Russian and Scandinavian/Baltic approaches respectively help to fill a comparatively large gap in readily available literature in the English language The synusial approach to classification is admirably dealt with by Barkman who covers a wide range of applications from epiphyte societies to aquatic vegetation types In their exposition of the Braun–Blanquet methods, Westhoff and van der Maarel provide what is perhaps the best insight into the methodology in all its facets that has yet been written in English A contribution on numerical taxonomy from Goodall completes this comprehensive section and the book

There can be no doubt that this work will become one of the ecological classics It is already my *vade mecum vegetatio* D W Shimwell

obituary

J. Bronowski

Dr Jacob Bronowski died on August 21, 1974, aged 66 A mathematician, he won acclaim for his work in popularising science in books, on radio and in television broadcasts

Bronowski was born in Poland and came to Britain in 1920 He read mathematics at the University of Cambridge from 1927 to 1930 and continued research there until 1933 A senior lecturer at the University of Hull from 1934 to 1942 he left to head a number of statistical units dealing with the effects of bombing In 1945 he wrote the classic report *The effects of the Atomic Bombs at Hiroshima and Nagasaki*

He was engaged in applying mathematical analysis to the economics of industry until 1950 when he became Director of the Coal Research Establishment of the National Coal Board and was responsible for the development of a new process for making smokeless fuel In 1964 he joined the Salk Institute for Biological Studies in San Diego, becoming Director of the Council for Biology in Human Affairs in 1970

Bronowski published many books including *Science and Human Values*, and *The Western Intellectual Tradition* He was a popular broadcaster and his most recent television series was the award winning *The Ascent of Man* made for the BBC

L. C. Craig

Lyman C Craig whose invention of the counter-current distribution process has been particularly useful for the isolation and study of synthetic antimalarials, antibiotics, hormones and proteins died on July 7, 1974

Dr Craig began his structural studies on the alkaloids of ergot in 1933, when he came to The Rockefeller University as an assistant to Dr W A Jacob, and later isolated lysergic acid During the Second World War he worked on the chemistry of antimalarial drugs for the Office of Scientific Research and Development

R. Cruickshank

Professor Robert Cruickshank, CBE, died on August 16, 1974 aged 74 He was prominent in forging many links between academic and public health microbiology

He graduated from the University of Aberdeen in 1922 and, in 1928, was appointed Lecturer in Bacteriology at the University of Glasgow and Bacteriologist to Glasgow Royal Infirmary Eight years later he became one of the first group pathologists of the London County Council and, in 1945, was appointed Director of the Central Public Health Laboratory Service He succeeded Alexander Fleming as Professor of Bacteriology at St Mary's Hospital in 1948 and became Director of the Wright Fleming Institute of Microbiology From 1958 until his retirement in 1966 he was Professor of Bacteriology at the University of Edinburgh

Announcements

Appointment

G. R. Serjeant has been appointed director of the **Medical Research Council's Epidemiology Unit** in Jamaica

International meetings

September 23–27, **22nd Symposium of Vertebrate Palaeontology and Comparative Anatomy,** Manchester (D W Yalden, Organiser, 22nd Symposium of Vertebrate Palaeontology and Comparative Anatomy, Department of Zoology, The University, Manchester M13 9PL, UK)

October 2–5, **International Conference on Surgery, Traumatology, Angiology Anaesthesiology and Reanimation,** Budapest (Office for Conference Organisation, (MOTESZ) H-1361 Budapest, POB 32, Hungary)

October 3–6, **6th International Symposium on Clinical Pharmacology and Annual Meeting of the International Society of Clinical Pharmacology,** Regensburg (International Symposia on Clinical Pharmacology, General Office, D-8400 Regensburg 1, PO Box 345, German Federal Republic)

October 7–12, **International Exhibition and Symposium on Elements and Systems for the Preparation, Collection and Transmission of Data and other Peripheral Units of Computers: DATOS 74,** Bratislava (House of Technology of the Slovak Scientific and Technological Society, Bratislava, Kocelova 17, Czechoslovakia)

October 14–16, **2nd International Symposium on Oncogenesis and Herpes-Virus,** Erlangen (Dr H zur Hausen, Institut fur Klinische Virologie, Erlangen, Germany)

October 16–18, **6th Meeting of the International Society of Paediatric Oncology,** Genoa (Sixth Meeting of the International Society of Paediatric Oncology, Department of Paediatric Haematology and Oncology, Inst Giannina Gaslini, via 5 Maggio 39, 16418 Genova-Quarto, Italy)

October 21–25, **International Conference on the Properties of Hydrazine and its Potential Applications as an Energy Source,** Poitiers (Centre National d'Etudes Spatiales (CNES), Department des Affaires Universitaires, 129 rue de l'Universite, 75327 Paris Cedex 07, France)

October 27–November 1, **8th Pan American Congress of Endocrinology,** Buenos Aires (Secretariat, CENI S A, Avda Rogue Saenz Pena 1110, Casillo de Correro 2539, Buenos Aires, Argentina)

October 28–November 2, **International Conference on Plasma Theory,** Kiev (Professor Sitenko, Institute of Theoretical Physics, Metrologicheskaya St, 14-Kiev, USSR)

November 4–7, **5th European Meeting of Radioisotope Producers,** Athens (P Papadimitropoulos, Director External Relations Divisions, Greek Atomic Energy Commission, Nuclear Research Center, 'Demokritos', Aghia Paraskevi Attikis, Athens, Greece)

November 4–8, **3rd International Symposium on Critical Care,** Rio de Janeiro (Dr Brenildo Tavares, Director, International Symposia on Critical Care, C Postal 14700, ZC-95, Rio de Janeiro, Guanabara, Brazil) ●

November 4–13, **9th International Scientific Congress on the Cultivation of Edible Fungi (Part 1),** Tokyo (9th International Scientific Congress on the Cultivation of Edible Fungi, Dr K Ono, c/o Secretariat, RN606, Second Mitsui Building, 12-chome Muromachi, Nihonbashi, Chuo-ku, Tokyo, Japan)

November 5–6, **London Symposium on Radioimmunoassay,** London (Scientific Symposia Ltd, 121 King Street, London W6 9JG)

November 6, **Electron Beam Effects at Surfaces,** London (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1X 8QX)

November 9–11, **5th Symposium on Plasma Physics and Controlled Nuclear Fusion Research,** Tokyo (International Atomic Energy Agency, P O Box 590, A-1011, Vienna, Austria)

November 15–18, **9th International Scientific Congress on the Cultivation of Edible Fungi (Part 2),** Taipeh (Dr Ren-jong Chiu, JCRR, 37 Nan Hai Road, Taipeh, Taiwan)

November 20–25, **Symposium on Foetal Antigen Expression in Cancer,** Isawa, Japan (Dr E Alpert, Harvard Medical School, Massachusetts General Hospital, Boston, Massachusetts, USA *or* Dr H Hirai, International Research Group for Carcino-embryonic Antigens, Hokkaido University Medical School, Sapporo, Hokkaido, Japan)

November 21–22, **Symposium on Nutrition and Aging,** New York (Director, Institute of Human Nutrition, Columbia University, 511 West 166th Street, New York, N Y 10032)

November 26–28, **Conference on the High Temperature Reactor and Process Applications,** London (British Nuclear Energy Society, Institution of Civil Engineers, 1–7 Great George Street, London SW1P 3AA)

Erratum

In the article "Structure of yeast phenylalanine tRNA at 3 Å resolution" by J D Robertus *et al* (*Nature*, **250**, 546, 1974) the last sentence of the legend to Fig 6 should read 'The region marked f is explained in the text as region 6'

nature

Volume 251 September 20, 1974

Right and wrong ways of expressing concern

We publish a letter from Professor F. Janouch on page 181 which together with the appeal from Professor B. Peleska to the World Federation of Scientific Workers (WFSW) (*Nature*, July 12) makes for most disturbing reading.

For a long time there has been talk of the miseries of some members of the academic profession in Czechoslovakia whose political views did not accord with those of the government. Much of this talk, however, has been coupled with a fear that to name names in the West would simply lead to greater personal distress in the East. And some of the talk has been simply of a subjective nature from visitors—that Prague has become 'the most miserable of capitals' and so on. Fear of naming names is not ill-founded; Professor Peleska has already, it is said, been visited by the police in connection with the letter sent to the WFSW and reprinted with his permission in *Nature*.

Czechoslovakia then, according to many with whom we have spoken, is at present about as bad a place as any to be an academic devoted to the spirit of liberal enquiry and freedom from repression. What can academics do in a public sense about preventing a breakdown in the standards which they regard as proper for the pursuit of learning? There are, we believe, no essential differences in approach between concern for Czechoslovakia and concern for, say, Chile.

It is easier, of course, to spell out what they shouldn't do.

- They shouldn't assume that an intellectually distinguished body is capable of leading the way diplomatically. The Royal Society in Britain, for instance, has been under much criticism in recent years for its failure to come out publicly on such issues as Soviet treatment of certain scientists. The standard defence is that much good work is done behind the scenes in person-to-person meetings with opposite numbers. This may well be true, but surely the real answer is that a society founded on intellectual distinction should not be asked to do a job requiring a high degree of political acumen.
- They shouldn't expect a politically committed body to deliver the goods. The WFSW has done some excellent bridge-building in the past and may appear, through its clear links with Eastern Europe, to be just the right vehicle for transmitting criticism. But the links with the East have been at the expense of strength in the West and particularly in the United States where an enormous number of scientific workers are and yet where few have ven heard of the federation. It is sad that Professor Burhop, president of the federation, should have chosen o respond to the appearance of the Peleska letter by counter-examples of western victimisation, but it shows e weakness of any organisation which as the Roses put it in *Science and Society* is a victim of cold-war and East–West polarisation.
- They shouldn't confine their concern to th specialisation. An academic community divi science, sociology and the arts or whatever is w may be to the point of ineffectualness. The learning must be indivisible on such matters.

But what positive steps are there to recomm often academics have used the wrong channels protest? Two seem to be under-explored and wo more attention—the approach to politicians and th of the press.

The elected politician with either his access to, or desire to pose problems for, a government has bee underestimated as a means of applying pressure in shaping foreign policy. And the ability of foreign policy to include specific references to the problems of oppressed groups has been inadequately used by academics—although a start has recently been made in the inclusion of concern for Soviet Jews in US foreign policy. If a hundred professors in any one country took individual initiatives to harangue their representatives on a matter so obviously not involving self-interest, could that country's foreign policy remain unaltered?

If approaches to politicians might help on a national front, approaches to the journals could rapidly move information around the world in order to create the necessary international climate. Who can doubt that wide publicity of the preposterous behaviour of the Soviet authorities in excising names that displease them from published papers serves a valuable purpose. And the scientist in particular, wedded to the importance of documentary evidence is at once more able to appreciate hard fact and more likely to be able to supply it. It is all-but-impossible for an editor to resist a well-documented story.

A hundred years ago

The will of the late Girolamo Ponti, of Milan, which has just been published in the *London Gazette* by order of Lord Derby, is likely to give rise to some trouble before it can be carried into effect. The testator has bequeathed a considerable portion of his property to the "Academies of Science of London, Paris, and Vienna," to be divided among them in equal proportions, for the purpose in each case of founding, with the proceeds resulting from investment, two competitions yearly on the subjects of Mechanics, Agriculture, Physics and Chemistry, Travels by Sea and Land, and Literature. The committees to be appointed by the societies are instructed to give preference to those competitors who will have advanced any of the subjects mentioned by original discovery. The relatives of Signor Ponti are to dispute the will, and those London societies that think they have claims upon the legacy are urged to bring them forward at once. There can be no doubt which societies are meant in the case of Paris and Vienna; and at first sight there appears to be little doubt as to what body the title of "Academy of Science of London" would most appropriately apply.

From *Nature*, **10**, 427, Sept. 24, 1874.

Strategy for a hungry world

Dr D. S. Miller of Queen Elizabeth College, and Dr P. R. Payne of the London School of Hygiene and Tropical Medicine take issue with a recent article in Nature *on the value of amino acid supplementation, especially in developing countries.*

s been claimed on a number of ions during the past few years it is possible to bring about sub- tial improvements in the health well being of the poor people of world by the application of some atively cheap and simple technology. ich a possibility seems theoretically oubtful and we feel that it is most mportant that attention should not be distracted from the real problems of social and economic developments by exaggerated claims for the impact of some particular technique. It is for this reason that Aaron Altschul's restatement of the apparent benefits of fortification of foods with amino acids[1] needs a critical appraisal.

We might begin by pointing out the significant fact that although the advantages of adding amino acids to human foods have been vigorously promoted for at least 20 years, and the technology for doing so has been available for as long, there is to date not a single example of a controlled field trial on a population basis which has shown any measurable benefit to man. We believe there are both nutritional and logistic reasons for this.

The nutritional basis for amino acid fortification rests upon the proposition that a specific deficiency of protein is a common cause of ill health. Such a statement requires definition. It is important to distinguish between the physiological needs for protein as a nutrient and the desire for foods such as meat, milk, eggs and fish. It has been a consistent feature of the arguments of those who advocate protein or amino acid fortification as a cure for malnutrition that they confuse the problem of meeting physiological needs for protein with the problem of meeting demands for aesthetically satisfying diets. Perhaps it is not surprising that many people can see no way in which the demands of the rich for meat could (or even should) be moderated in the light of the needs of the poor for bread. It is surely hypocrisy to pretend on the one hand that these demands and needs are both expressions of the same protein problem, and on the other to suggest that the needs of the poor can be satisfied by fortification of staple foods with a tasteless, odourless powder which will help neither to satisfy hunger or incidentally to improve the nutritive value of the diet.

The second problem of definition is to distinguish between diets which are 'limited' by a particular amino acid and those which are 'deficient'. For example the traditional English breakfast of porridge, bacon and eggs, toast and coffee contains a protein mixture that if fed under carefully controlled conditions could be shown to be limited by methionine. But this is neither evidence that the UK population is at risk from methionine or protein deficiency, nor does it justify the fortification of breakfast foods with amino acids. A diet may only be considered deficient in an amino acid if it contains less than the requirements of the consumer.

Dr Altschul correctly points out that standards of protein requirements are now "lower than before". What he does not point out is that one takes the latest FAO/WHO standards[2], it can be shown that the required percentage of calories from protein in mixed diets as eaten by man is only 8%. This assumes that the efficiency of protein utilisation of human diets eaten in poor countries is about 65%. In fact, the calculated efficiency derived from the methods given by the FAO/WHO report is higher than this at about 90% which would lower the required percentage of dietary protein even more. Thus the cited projection that the protein content of the diets eaten in South Asia will fall from 10.2% to 9.8% by 1980 does not indicate impending disaster. Of course there are those who argue that the poorest people are eating bread or rice alone. These cereals will have an efficiency of utilisation about 50%, and hence the required protein content of the diet would rise to 10%, still covered by cereals alone. Another argument is that cereals do not contain enough protein for the vulnerable groups in the population such as preschool children. But the latest requirements indicate that they also require only 10% cereal protein as a percentage of the calories. Thus simple protein deficiency cannot occur in areas where cereals are the cheapest food, and amino acid supplementation would therefore be a wasted effort. Simple protein deficiency can only occur where the staple food contains less than 10% protein such as cassava, sago, and plantain. Since these foods contain virtually no protein, supplementation with a few amino acids cannot increase their useful protein content by changing protein quality.

This is not to say that there is no such thing as protein-calorie malnutrition. This syndrome arises chiefly because children do not eat enough food. It is complicated by disease, especially diarrhoea, respiratory infections and measles, but the prime cause is insufficient food. We were interested to read in the same issue of *Nature*, the account by Ethiopian relief workers and their critical assessment of protein-rich foods. Indeed your editorial correctly praised this group for their design of an energy-rich food for use in such situations. It is clearly non-

sense to supply developing countries with single nutrients, such as amino acids or vitamins, when some people are unable to buy and consume enough of the traditional diet which has sustained the population for centuries

Turning now to the logistic problems of amino acid fortification, we would suggest the following conditions before any project should be implemented

- That the limiting amino acid in the diet as distinct from the staple food, must be known The extent of the limitation must also be known In practice, cereal-based diets as eaten are found not to be limited by lysine Miller and Donoso[3] have shown that the limiting amino acid of most diets, including cereal diets, is methionine Also that the improvement in the effective protein content when methionine is added is trivial in comparison with the data cited by Dr Altschul concerning the effect of the addition of lysine to flour alone
- That the supplemented food is consumed by the vulnerable groups in the population This is normally only practicable where the staple foods are centrally processed and almost impossible where the major proportion of the population are subsistence farmers
- That the project is the cheapest method of improving the diet as a whole Since the chief cause of malnutrition is poverty, amino acid supplementation should be regarded by governments as an alternative to raising the standard of living Thus to compare a scheme for adding lysine to wheat with one for improving milk production from marginal grassland, purely on the basis of the yield of protein is misleading Improving agriculture provides employment, can be achieved within the country, and produces a product which is both aesthetically satisfying and acceptable Finally we must point out that Dr Altschul does not fully quote one of his references[4], which indicates that the cost of fortification of all cereals in India would be no less than 16% of the Central Government Budget, or approximately five times the money spent on health

We conclude that amino-acid fortification of staple foods should be rejected on nutritional and logistic grounds The best solution to the problem of malnutrition is to raise the standard of living and to improve traditional agriculture Aid to the subsistence farmers is the best way to achieve both

international news

Doubts over US in India

from Narender K Sehgal

THE World Health Organisation (WHO) has been carrying out allegedly secret research projects in India, financed by agencies of the U S government It has recently come to light that the U S Army has been an interested recipient of the research results from these projects

The WHO experiments are being conducted (some have been completed) at the Genetic Control of Mosquito Unit (GCMU) in New Delhi, Bombay Natural History Society (BNHS) and the malaria eradication station in Jodhpur (Rajasthan state) The projects in question relate to the genetic control of mosquitoes, bird migration and the like—seemingly scientific investigations, till one takes a closer look at the related details But Indian experts feel that the experiments could also provide data on the availability, behaviour and peculiarities of disease carriers in India—information that could be of value in biological or germ warfare

Until recently the GCMU had been collecting data on the ecology, behaviour and dispersal patterns of mosquitoes in South Delhi and in Faridabad, a sprawling industrial complex near the capital Some scientists have expressed fear that, using these data, an enemy could conceivably employ mosquitoes for the effective transmission of germs and viruses Also, the GCMU conducts most of its experiments in and around Delhi—an area known not to be endemic for malaria or filariasis—instead of in the really endemic areas around the country

The GCMU proposes to launch a big experiment early next year in Sonepat (again near Delhi) aimed at genetic control of *aedes aegypti*—in spite of the fact that the GCMU's first priorities ought to be malaria and filariasis carriers Malaria is back in India and filariasis is endemic in an area occupied by a fourth of the Indian population Dengue, unknown in India before July 1963 when it was detected for the first time in Calcutta, appears sporadically Yellow fever is nonexistent in India, not a single case having been reported in ages This, it is argued, may be because of some 'balancing virus' that ensures protection against this disease But the GCMU's genetic experiments could reduce or destroy this natural 'balance' and render the country vulnerable to yellow fever

Indian scientists taking part in the GCMU's projects point out that their project leaders are, and have been in the past, U S government scientists Two years ago, the GCMU attracted public attention when it was found to have been polluting village wells—apparently in the course of scientific experiments—with chemicals suspected to be cancer-causing and prohibited in the USA Since then secrecy around GCMU projects has been reportedly tightened

Another controversy that has been raging among the scientific community here has to do with the role of Indian scientists and research organisations in programmes sponsored jointly by the Migratory Animal Pathological Survey (MAPS) of the U S Armed Forces Institute of Pathology and WHO Reacting to criticism in the Indian Parliament the president of the Bombay Natural History Society, in a letter to a New Delhi daily, stoutly defended his society's collaboration with the MAPS on bird migration projects, he denied allegations of secrecy, ongoing collaboration arrangements with the MAPS and employment of U S personnel in bird migration studies

Following this a scientist of the Jawaharlal Nehru University in New Delhi, in a letter to the same daily, pointed out a few things the BNHS president forgot to mention in his letter Namely that (i) the blood samples of the birds caught by the BNHS were not analysed in India but were sent for the purpose to the Smithsonian Institute and the MAPS in the USA, (ii) two American scientists belonging to the Smithsonian were associated with the BNHS-MAPS programmes in India, (iii) the services of the BNHS and VRC (Virus Research

Centre of Poona) were made available to the U S Army agencies at nominal cost, (iv) the knowledge gained by the Indian scientists at BNHS and VRC was only partial, and probably the least significant if it did not include the details of the blood sample analyses and the overall data on bird movements and induced infections, and that (v) only a coordinating agency outside this country, which obtained comprehensive data from other units, could assess the military uses or significance of such experiments

There is no doubt that the WHO projects in India are carried out with the approval of the government of India through its ministry of health, but when the matter of involvement of the U S Army in some projects was raised in the Rajya Sabha (upper house of the Parliament) the government merely assured agitated members that it would see to it that national interests were not endangered by these projects This routine assurance to Parliament members has not impressed many in the scientific community, and demands are being made for a thorough probe into the whole situation □

Science policy in the Netherlands

from Arie de Kool, Rotterdam

DISCUSSIONS on science policy are running so high in the Netherlands that even scientists are beginning to take an interest The radical Bond van wetenschappelijke arbeiders (Union of Scientific Labourers) has been publishing reports on science policy ever since it was established about six years ago, and recently they have begun to cooperate closely with the Pugwash-based Verbond van wetenschappelijke onderzoekers (Union of Researchers) Together, the two unions have brought out a joint proposal for a democratic structure for science policy

Their proposed structure is supposed to keep technocracy out, and guarantee a maximum amount of freedom and power over his own work for the research worker while at the same time safeguarding scientific standards It is based on university organisation where one finds at the lowest level a section (for example, the solid state physics section or the French section), governed by a council on which scientific staff, technical assistants and students are represented (but in such a way that students can never obtain a majority) Several sections form a faculty, with its own council

According to the new proposal the sections would not only join within the university, but all sections for, say, solid state physics, would elect a "working community" at a national level This working community would advise upward on the urgency of different programmes, and also receive money to pass out to the working groups in the universities In fact working communities are now functioning rather well on the average, doing exactly this There would be two differences, they would be elected by the scientists involved (and not appointed by the Dutch version of the National Science Foundation, ZWO, or one of its subsidiaries), and they would be responsible for about one third of the money going to a specific discipline

Over and above the councils, we are to find a national council for higher education and scientific research This is an almost purely political body, to advise government and parliament on matters contained in the name, and at the same time an executive body, handling all the money One third of the research money would go to the universities to be spent at will (as long as it is for research, the democratic structure of the university is supposed to guarantee that this money is well spent) About one third goes to the universities, but would have to be spent in the faculties more or less proportionally to the number of students And one third would go to the discipline councils to hand further down

The idea behind this being that one needs a certain degree of centralisation if one wants any science policy at all On the other hand, too much of it tends to kill the initiative, and close off new roads and new research, while there may be a strong tendency to overemphasise certain fashionable fields In this structure, one would see about one third handled centrally, about one third at the university level, and about one third (the per-student amount) "at the basis", in the working group itself At any level the researcher is supposed to have a certain degree of influence through his representatives, but of course, this private influence diminishes as one goes up higher in the structure

Industry has been almost left out The report says that since none of the proposed institutions could be expected to effectively exert power over industrial science, it would be wrong to have an industrial influence in the different councils However, a better coordination of industrial and university research in socially relevant fields, is seen as worthwhile In the long run government might even want to stimulate industrial research in those fields, and want to put a brake to other fields Therefore industry should be asked to report on its scientific and technical activities, for instance, to the national council □

Trouble in the air

by Colin Norman, Washington

FOR the past couple of years a number of industrial groups, taking their cue from the automobile industry, have been waging a pitched battle against some of the Federal government's plans for cleaning up air pollution Their prime objective has been to persuade Congress to emasculate some key provisions of the Clean Air Act—the foundation of the government's air pollution strategy—which they consider unduly stringent, scientifically invalid and, of course, inordinately expensive

But the rug was pulled from under industry's feet last week when the National Academy of Sciences unveiled a massive study of the Clean Air Act and its scientific foundation Although the committee which conducted the study posed more questions than it answered, and hedged all its conclusions with a string of qualifications, it said that there is "no substantial basis" for weakening key provisions in the act, and that the costs of cleaning up automobile emissions are at least commensurate with the benefits

A few Congressional staff members centrally involved in the debate over air pollution standards all said in response to inquiries last week that the Academy's study will probably provide Congress with sufficient ammunition to ward off challenges to the Clean Air Act which are certain to arise next year—the act is due for review and possible amendment in 1975

The Clean Air Act sets maximum levels of various pollutants which are allowed in the atmosphere, the chief intent of these so-called air quality standards being to protect public health In addition, the act specifies maximum levels of hydrocarbons and oxides of nitrogen which can be discharged by new automobiles The air quality standards have, however, been attacked for being stricter that necessary to protect public health, and the automobile emission standards have come under fire for being too costly to meet

But the Academy's study, which was conducted under contract to the Senate Public Works Committee, said that the standards have, in general, been supported by the evidence which has accumulated in the three years since they were set Moreover, "the safety factors provided by the air standards are much smaller than is usual in regulating other environmental pollutants such as radioactivity", the study concluded

In fact, using calculations which are admittedly uncertain but which are derived from a variety of sources, the Academy committee reckons that auto-

Washington seen

by Colin Norman

Ever since Gerald Ford was elevated to the Presidency early last month, there has been a good deal of speculation among members of the scientific establishment on whether or not he will resurrect some of the White House science policy machinery which his predecessor abolished. With galloping inflation and Presidential pardons keeping him occupied, Ford has, of course, shown no indication of rushing to deal with the matter, but there are a few suggestions that perhaps he might attend to it at some time.

First, he met earlier this year with a number of scientific society presidents and was reported to be receptive to the need for a scientific presence to be reestablished in the White House. Second, he was personally briefed on the recent report of the National Academy of Sciences which urged him to bring the science policy machinery back in from the National Science Foundation, which is where Nixon dispatched it. He was said to be a willing listener. And third, his nomination of Nelson Rockefeller as Vice President brings to the White House a man who is well known for seeking out science advice, albeit mostly from Edward Teller, the so-called father of the United States H-bomb.

But perhaps the most decisive move could come from Congress. Last month, the Senate Commerce Committee reported out a bill which would set up a Council of Science and Technology Advisers at the President's elbow. The bill has also been referred to the Senate Committee on Aeronautical and Space Sciences, which will probably approve it this week. There is thus a chance that the idea will get the blessing of the entire Senate before it adjourns in mid-October, in which case the whole matter will be brought rather abruptly to Ford's attention.

So far, however, nobody has been able to demonstrate convincingly that the present arrangement is not working properly, or that a White House science policy office would work any better under Ford than it did under Nixon.

● Officials at the National Science Foundation are now trying to decide how to apportion a $20 million budget cut which was recently imposed by Congress, but they have little choice except to take virtually all of it out of basic research.

Congress, demonstrating once again that its rhetoric in support of science and technology doesn't count for much when it actually comes to spending money, cut $20.05 million from the budget request for NSF, but also directed the foundation to spend some $6.8 million more than it wanted on a few politically sensitive education programmes. The upshot is that $26.85 million must be shaved from other NSF activities.

Congress itself dictated that at least $5.5 million must be taken from the programme of Research Applied to National Needs (RANN), and that another $1.4 million should come from a research management programme, but it left NSF officials free to decide where to cut the other $20 million.

According to NSF budgetary officers, however, the only area that can be cut is the foundation's support of basic university science, and they reckon that as much as $18 million could come from there.

In language uncharacteristically blunt for that decorous institution, the National Academy of Sciences has criticised the Environmental Protection Agency's management of its research and development activities, and has suggested that EPA should scrap its present planning and management procedures and devise some new ones.

The criticisms were contained in a report drawn up by an ad-hoc Academy committee under the chairmanship of Dr Robert W. Berliner, former Deputy Director of the National Institutes of Health.

The committee found that planning of EPA's research and development programmes is separated from responsibility for their execution, which has led to "severe resentment" among the agency's scientists. Research priorities do not necessarily reflect the needs of EPA's regulatory officers, the planning system is excessively complex and detailed, there is no long term research programme designed to meet environmental needs, and "relationships between the headquarters and field (staff) are strained at best".

The committee also noted that the fact that EPA's research and development budget has been held constant for the past few years doesn't help matters.

To help remedy the situation, the committee suggests that the present arrangements should be scrapped, that the directors of EPA's laboratories should be given more of a say in the planning process, and that the headquarters staff should be trimmed by decentralising some of the control.

The report is the first to emerge from a $5 million contract between EPA and the Academy under which the Academy will conduct a comprehensive study of EPA's activities. The study was mandated by Congress at the urging of Mississippi Congressman Jamie Whitten, a strong supporter of DDT and other pesticides, who believes that EPA is out to destroy American agriculture.

---

mobile pollution could now account for as many as 4,000 deaths and four million days of illness among Americans each year. That represents about one-eighth of the deaths from bronchitis, emphysema and asthma, and one-tenth of the days lost from work each year from respiratory illness.

The committee told Congress that it sees no reason to alter any of the air quality or automobile emission standards, although it does suggest that the standard relating to emission of oxides of nitrogen by automobiles "may be somewhat more stringent than is needed". But the automobile companies will find it difficult even to use that suggestion as ammunition against the Clean Air Act, since the Academy committee says in the next breath that since little is known about interactions between oxides of nitrogen and hydrocarbons in the atmosphere, it would be unwise to relax the standard at this time.

Finally, an amusing footnote to the debate over automobile pollution was provided last week by General Motors. When the exhaust emission standards were first set, the entire automobile industry rose up in arms because the timetable for meeting the standards was so short that they would have to invest huge sums of money in exhaust catalysts—no other technology would have been available in time.

Motor manufacturers argued vehemently that catalysts would be unreliable, that they would decrease engine performance, and that they would greatly increase gasoline consumption. But Congress refused to scrap the timetable and many of the 1975 model cars which still come onto the market this month will be equipped with catalysts. General Motors has consequently changed its tune.

According to a series of full-page newspaper advertisements which the company took out last week: "General Motors believes it has an answer to the automotive air pollution problem . . . and the catalytic converter has enabled GM engineers to improve performance and to increase miles per gallon." It's amazing what a little government pressure can do. ☐

Vancouver boycott supports Plyushch

from Vera Rich

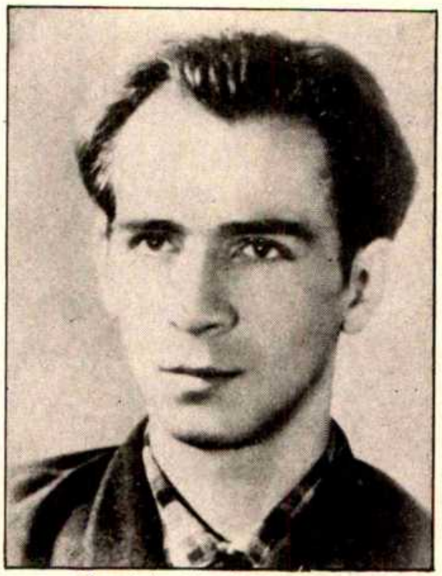
THE right of a scientist to travel abroad for professional purposes is one of the most vexed questions confronting campaigners for human rights in the USSR. Recently the greatest attention has been focused on those Jewish scientists who wish to leave the Soviet Union permanently and settle in Israel—a desire usually denied either on the grounds that the scientist concerned has allegedly had access to classified information, or else that he represents an asset to the State in terms of education and experience. (The fact that scientists who apply for a visa to Israel tend to be fairly rapidly dismissed from their posts does not entirely vitiate the latter argument —the authorities may not wish to make use of the services of these valuable personnel, but they do not wish their services made available elsewhere).

The case of scientists who wish for a temporary visa is far less defensible. These scientists simply wish to travel abroad to a conference, deliver their paper, and return home. There is no question of settling abroad; they wish merely to make a temporary visit. Yet all too frequently, invited scientists fail to arrive at conferences, and their places are filled by uninvited representatives of the Soviet Union, who have little or no no reputation in the field concerned, and who insist on delivering papers which often have only a very peripheral connection with the subject of the conference.

This substitution of delegates can, however, possibly be turned to good account by those who wish to press for academic freedom for their Soviet colleagues. At the recent International Congress of Mathematicians in Vancouver, a number of participants decided to boycott the papers of such uninvited delegates as a protest against the persecution of a number of Soviet mathematicians, notably that of Leonid Plyushch, whose fate was also the subject of an appeal to the Congress by Dr Andrei Sakharov, the founder of the illegal "human rights" movement in the Soviet Union.

Plyushch, a mathematician and cybernetician, was formerly employed at the Cybernetics Institute of the Academy of Sciences of the Ukrainian SSR, specialising in the computer simulation of biological and biochemical processes. In 1968, he was dismissed from his post as the result of a letter which he wrote to the newspaper *Komsomolskaya Pravda*, protesting against the illegality of the trial of the writers Ginsberg and Galanskov. In 1969, he became a founder-member of the illegal "Initiative Group for the Defence of Human Rights", founded by Dr Andrei Sakharov. In 1972, after almost four years without work, and a number of interrogations and harassments, Plyushch was arrested on January 17, 1972, under Article 62 of the Criminal Code of the Ukrainian SSR for 'anti-Soviet activities'. His arrest formed part of a general campaign against the *samizdat* journals *Chronicle of Current Events* and the *Ukrainian Herald*. In January 1973, he was sentenced *in absentia* to indefinite confinement in a special mental institution, suffering, it would appear, from that notable discovery of Drs Lunts, Morozov, *et al.*: "schizophrenia leading to ideas of reform making."

Since then he has been confined in the Dnepropetrovsk "special" psychiatric hospital, and an appeal dated February 12, 1974, and signed by six leading intellectuals including Sakharov, which reached the West via the *Samizdat* network, speaks of the "appalling conditions of humiliation, persecution and physical suffering" in which he is held. Intensive "treatment" with haloperidol has caused a "sharp deterioration in his health, extreme exhaustion and continuous shivering, weakness, swellings, spasms, and loss of appetite." By that time he could no longer read, write letters or take advantage of the hour's exercise permitted to confinees. All requests by his wife for information on her husband's state of health, and treatment were refused.



Plyushch : *"at the border of death"*

Shortly after this appeal was drafted, an International Committee of Mathematicians for the Defence of Shikhanovich and Plyushch was set up in Paris. (Dr Yurii Skhikhanovich is a Moscow logician who was being held on charges similar to those against Plyushch.) After a number of requests to the Soviet embassy in Paris for news of the two mathematicians, the Committee was informed that the diplomats were "inadequately informed" in these matters, but that the Soviet Union never used confinement in a mental hospital as a punitive measure, and that the "special" hospitals such as that in which Plyushch is confined were established so that scientists could receive especially good treatment and care. Later requests produced the 'information' that Plyushch was dismissed for negligence in his work and for having lost departmental documents. After which he made no attempt to find further work, but engaged in writing and circulating anti-Soviet material. During the judicial enquiry into these activities he was found to be suffering from schizophrenia and was still (March 25, 1974) in need of medical treatment. A reexamination of Shikhanovich "in order to consider the possibility of terminating his course of treatment" was scheduled for March, and in June, he was in fact released, apparently in response to the Committee's pressures.

But Plyushch remains in confinement, perhaps on account of his Ukrainian nationality. Ukrainian dissidents, with their stress on equal rights for minority nationalities (and in particular for their own 50-million-strong 'minority') are always viewed considerably more severely by the Moscow authorities, lest nationalism should lead to a revival of Ukrainian separatism. (The Ukrainian SSR, like the other Union republics, does, of course, possess on paper the right to secede from the Soviet Union.)

Whatever the reason for his continued confinement, the conditions in which he is held according to the appeal of last February, have brought him "to the border of death", and even if he survives there is a real danger of irreversible psychological and intellectual damage.

It is not surprising, therefore, that appeals should have been made to the Vancouver Congress, both from the Paris Committee and directly from Sakharov, to "pass a resolution in Plyushch's defence, and to take all possible measures to save him." What is new is the suggested means of protest and the boycotting of uninvited papers. A great deal may be said in favour of international academic exchange with the Soviet Union, as a means of fostering *detente* and of opening channels through which pressures can be exerted, when necessary, for the defence of academic freedom. However, the long-standing Soviet practice of sending substitutes to international conferences must inevitably tend to vitiate these advantages. The recent appeal on behalf of Leonid Plyushch, if the proposed boycott becomes a regular reaction, may put an end to the high-handed attitude of the Soviet authorities in denying visas to invited delegates. ☐

● News has just been received that Moscow physicist Viktor Polskii, who has been trying for four years to obtain an exit visa to emigrate to Israel, is to be brought to trial on Friday September 20, 1974. Dr Polskii who was dismissed from his post as Director of an X-ray Introscopy laboratory in 1971 after applying for his visa, has several times been threatened with trial and imprisonment, if he would not withdraw his application.

In March, 1974, the authorities received an unexpected stroke of luck when a 19-year-old girl tried to commit suicide by throwing herself under Polskii's car, following a quarrel with her parents. Although she and her parents at first admitted the suicide attempt, they later changed their testimony and now claim that she simply ran across the street. Dr Polskii is therefore faced with prosecution on a charge which carries a maximum sentence of "deprivation of freedom for three years".

The trial, at first scheduled for August 15, was postponed indefinitely, on the grounds that Polskii needed an operation for hernia. There was some speculation that this was a diplomatic retreat on the part of authorities, especially since it seemed that Dr Tsibin, who admitted the girl to hospital following the incident, was prepared to substantiate that she did, in fact attempt suicide. It was felt that the postponement would lead to the charge being quietly dropped.

This, however, is not the case. The trial is to go forward, and the timing of the announcement, during the Jewish High Holidays, seems to carry considerable overtones of propaganda to discourage others.

Professor F. Janouch, of the Niels Bohr Institute, Copenhagen, writes on the plight of the Czechoslovakian academic

PROFESSOR Peleska's letter to *Nature* (July 12), a shocking document, is but one example of the great devastation of the Czechoslovak science and culture, which started back in 1969-70. It is almost impossible to collect all cases of this continuing persecution and one could hardly find a journal or editor willing and able to publish the endless lists of tragedies and frustrations of Czechoslovak scholars and intellectuals.

Professor Burhop's comments (August 9) are too mild and indecisive. No scientist is against international cooperation in science. But what meaning has such cooperation *per se* without any conditions? I am afraid that the damage caused by closed mouths and eyes (which, in fact, is the price for such unconditional "cooperation") is much greater than possible effects.

Professor Burhop reported two further cases of persecution of scientists. The first one—of Ferreiro de Alencar—belongs to cases of judicial persecution, the second—the dismissal of Holzer because of his membership to the Communist Party—belongs to what may be called extrajudicial persecution.

To the first category of judicial persecution of scientists several examples from my country Czechoslovakia could be added. Let me give here only the names of historians Professor Hubl and Dr Tesar, and a psychologist, Professor Sabata, all these are serving sentences exceeding six years for their political activity. It will no doubt be very useful and it will certainly only increase the prestige of WFSW if they would show more initiative in collecting, publishing and condemning such cases of judicial persecution no matter where and when they may happen.

The extrajudicial persecution of scholars and intellectuals is widespread throughout the world, in my country at present it has the dimension of a national catastrophe. The numbers of Czechoslovak intellectuals fired for taking stands, for expressing and defending their opinions, who cannot work in their field (or have difficulties with their self realisation for these reasons) are perhaps being measured now by tens of thousands—too many for a country of 14 millions which can assert itself solely by the extent to which it can contribute to the common culture and is able to help others with experience and knowledge.

I join the protests against the dismissal of Holzer. It seems to me, however, and this is not properly understood in Western countries, that his dismissal, however tragic, does not prevent him from continuing his scientific career, does not prevent him from publishing his papers or books, does not concern the very existence of himself and even of members of his family.

The extrajudical persecution in so-called socialist countries, with the absolute monopoly of political power concentrated in one party or even in a very small group of people, with strict censorship of all mass media, with nationalisation of all branches of education, science, culture, trade, industry, administration and mass media, is incomparably more severe and effective. A man, subjected to extrajudicial persecution in these countries, has no other choice than to take unqualified, manual work. With few exceptions, which may be counted on the fingers of one hand, Czechoslovak intellectuals have no possibility of leaving the country to find work abroad. Their children are deprived the right of education at schools and universities. Their papers and books cannot be published. Let me mention here the shameful instruction issued by Czech Education Minister J Havlín on May 19, 1972, according to which "it is not permitted to publish authors, who have been expelled from the Communist Party of Czechoslovakia, have been dismissed for political reasons from the university or emigrated illegally abroad." I have tried to protest against this, in my opinion, unconstitutional and immoral instruction. The Prosecutor General of the Czech Socialist Republic did not, however, find it necessary to intervene over Havlín's instruction. Such practice, hence, has to be considered as legal in my country.

The consequence of extrajudicial persecution is the isolation from science, which is in our days of rapid development and frequent changes in all fields of science equivalent to scientific disqualification and consequent intellectual death.

Let me point out yet another aspect of Professor Peleska's case: preventing a physician from performing his profession, developing new methods for the treatment of people, easing their suffering, and saving human lives is a crime against humanity—the worse crime because it is covering itself with an ideology which pretends to be the most progressive and most humane one.

The WFSW, no doubt, is aware of the fate of one of the most renowned Czechoslovak scientists, microbiologist Academician Ivan Málek (one of the WFSW founders and for a long time its Vice-President). In autumn 1973, Professor Málek lost his position at his institute and is now being deprived of any possibility of continuing his scientific work. Even his library and his scientific archives have been thrown out of the institute, which Málek founded, built up and directed for almost 20 years. Why does the WSFW remain silent in the fact of such intellectual barbarism? We are living in an open world, and only open, public stands, protests and statements are meaningful and helpful. Intellectual freedom is indivisible, and if world scientific and intellectual organisations continue their ostrich politics with respect to the fates of their persecuted colleagues, they will not only lose the moral right to speak on behalf of the world intellectual community, they will lose their intellectual freedom too.

correspondence

Whales

SIR,—With reference to the article "The Unendangered Whale" (August 9), we feel that it is most important to point out that the opinions expressed by Dr Ray Gambell are by no means universally accepted

Gambell states that the "concept of species management is now operative" But 'concepts' do not ensure that the whales will be harvested rationally There are many more practical factors which come into play besides scientific concepts of species management At the International Whaling Commission (IWC) meeting last June, some of the recommendations of the Scientific Committee (of which Gambell is a member) were overruled in the plenary session in favour of higher quotas It is also worth noting that there is still time for Japan and the Soviet Union to opt out of any of the management policies under the 90-day rule In fact, there is no real need for Japan to opt out of any of the decisions made by the IWC as she owns dummy companies (joint ventures, flags of convenience) in countries which do not even belong to the IWC

Gambell also points out that it also "remains to be seen just how well the scientists can resist the political and economic pressures" Past experience (of which there is much) suggests that they are unlikely to be able to resist such pressures Some Japanese whaling scientists have admitted that they are torn between the demands of the Japanese whaling industry and the necessity for sound conservation measures

The reason why many experts are now opting for a 10-year moratorium on commercial whaling is because they have begun to realise how little they know about whales and the effect of whaling on their populations Gambell is not one of these scientists, but he has conceded that "there is much research needed" It has also recently been brought to Gambell's attention that perhaps the biomass of whales should be studied, not just their numbers Had the scientists looked at the wider effects of whaling–other than those demanded by the industry-dominated IWC–they would have seen that the weight of sperm whales, for example, has declined rapidly during the past 30 years, and that in terms of biomass is probably well below maximum sustainable yield (MSY) There is also reason to believe that the total biomass of baleen whales in the Antarctic is also well below MSY We feel, therefore, that Gambell is rather premature in reporting that the whales, situation is satisfactory

Fortunately the British government is still in support of the complete moratorium on commercial whaling despite Gambell's advice

Yours faithfully,

Biohazards and the law

SIR,— Brian Ford (*Nature*, August 2) may be right in saying that there is not enough *statute* law about biohazards, and his suggestions for future legislation are certainly valuable But statutory codes of practice cannot by themselves solve the problem Sooner or later, by accident or design, someone somewhere will ignore them What is important is what happens then

The offender may be fined or sent to prison, but that will provide little comfort for the victim Far more important is the civil remedy which the *common law* (i e the law made by the judges) has designed for such cases, centuries before Parliament started to take an interest in this field

Under the rule known as Rylands v Fletcher, anyone who for his own purposes keeps on his land anything likely to do mischief if it escapes is answerable for all the damage which is the natural consequence of its escape The liability does not depend on negligence all the victim has to prove is that the mischievous thing was kept there, escaped, and caused him damage, and it avails the defendant nothing to show that he took all possible care, or even that he did not know the thing was dangerous

There are cases in the books, as recently as 1928, which apply this rule to poisonous substances I know of no reason why the courts should not apply it to living organisms—though, if they were held to be animals, they would now come under the Animals Act 1971, which replaces common law rules broadly similar to the rule in Rylands v Fletcher

If every owner, director and operator of a laboratory which kept human pathogens on its premises realised that in the event of an escape he would be absolutely liable to compensate all victims for all the damage they suffered, the standards of care to prevent escape from those laboratories might well be higher, and more strictly observed, than any new legislation could expect to achieve

Yours faithfully,

Megalithic alignments

SIR,—As one who has recently reviewed several of John Michell's books at some length *Men, myths and megaliths*, Thames and Hudson, in the press), I read his letter (August 23) with considerable interest

To anyone who has made the effort to wade through the corpus of his bizarre geomancies, it comes as no surprise that most archaeologists have declined the privilege of reviewing his latest efforts I suspect that many regular readers of *Nature* will be unfamiliar with Mr Michell's books and his ideas Basically he is a neo-Straight-tracker, a disciple of Alfred Watkins (*The Old Straight Track*, Methuen, 1925) who believed, after a mountain-top 'vision' one summer afternoon in about 1920, that Britain was networked with alignments (including Megalithic ones) which had been laid out in premeditated fashion by some ancient race

But Michell is also a self-confessed flying-saucer enthusiast, an admirer of Piazzi Smyth's Pyramid theories, Mrs Maltwood's Glastonbury zodiac and several other claptrap cults which provide the right kind of fuel for his own romances

Michell's technique, rather cunningly, is to throw in any semi-respectable or respectable material in attempts to add verisimilitude to his own For example, Fred Hoyle must be 'delighted' to find that Michell is a staunch supporter of his 'Stonehenge drum-beat theory' (about 1966) In *The View Over Atlantis* (Abacus, 1973) he writes (page 183) 'Professor Hoyle in an article in *Antiquity* suggested that the men who built Stonehenge may have communicated over long distances by beating drums ' and then Michell splices in his own ideas ' it was with drums, songs and the clash of cymbals that magical flight was achieved according to legend

Stone levitated by sound could become a flying chariot moving along the line of a certain magnetic intensity, whose course was marked out on the ground by alignments of stones and earthworks, linked by raised causeways and rides through the forest With the Earth's magnetic [sic] field regulated and the streams that run through it diverted to conform to straight lines, the stone craft and its navigator could float from centre to centre, picking their way through a canal network of alternating currents and choosing the level of intensity to which their vibrations were attuned'

Geophysicists also please note!

Yours faithfully,
P Lancaster Brown

Closely observed trains

Sir,—The facile comment under the photograph on page six of your journal of the 6th of September, prompts me to raise a few points with regard to the present state of magnetic suspension technology in this country and abroad

How good at speed? Your correspondent gives the answer herself on page seven The 45 mile track being constructed in Germany is for a high speed system using controlled electromagnets The proposed speeds are 500 km/h Krauss Maffei have no problems that they cannot overcome on eddy currents up to 400-450 m p h Our own tests confirm the Krauss Maffei measurements made in 1972 when they ran their vehicle at over 150 k p h Nobody in their right minds and connected with the d c electromagnet suspension technology would see any problems at speeds as low as 50 m p h The problems at Toronto are those of linear induction motors and the inverter drive for them It is also worth noting that work on the French Aerotrain has come to a halt and discussions have taken place between the French and German authorities on a joint programme of development of the controlled electromagnet systems, for intercity and transeuropean network So much for the misplaced Sussex claims

There is in my opinion, an obsession with high speed and ground transport which in turn leads to a complete blinding of the technical problems (never mind the social problems) of high speed vehicles Guidance of such vehicles is not a matter of showing that 20lb aluminium plates or one ton vehicles in laboratories have stability The turning moments on a 30 ton, 100 passenger vehicle are of the order of 40000 N M The aerodynamic drag alone is more than 2000 kW and therefore that is the size of the required linear motor (The suspension power using d c electromagnets is 30 kW)

No-one claims to have solved the problem of collecting this sort of power at 300 m p h from what your correspondent calls "normal a c mains" It is a little bit more difficult than plugging a shaver into a socket If two of these trains cross each other this will impose an impulse load of more than four MegaWatts on the area generating board Is the generating board going to be happy about this happening at three min intervals? Are the high speed vehicles to run from A to B only or are they intended to change routes at speed? If yes, has some consideration been given to each proposal including the tracked hovercraft? The cost apart, these are some of the more formidable problems of high speed transportation vehicles There are a few mundane ones like response times of the guidance systems, an accurate estimate of propulsion and suspension powers (no-one gets this as a bonus, as has been claimed), dependence of guidance and suspension forces on speed, power factors and efficiencies of the proposed equipment to name a few

My team and I have lived with these problems for the last five years and are in a position to offer experimental evidence on suspension, guidance and propulsion aspects (including eddy current drag) We do not claim to have solved the world's transportation problems or to offer the ultimate system The Germans have been developing their d c electromagnet systems for the last three years and are going ahead with the same technology for high speed application The Japanese on the other hand have run into serious problems of guidance on their cryogenic system We could investigate our system on the Brighton seafront to find out (a) whether it is possible to implement it in our cities and (b) whether a high speed system is feasible Alternatively, we could always buy the finished article from Germany say, in 1985 or 1990

The choice of Brighton seafront is not so gimicky as it appears Environmentally it is one of the toughest locations one could choose with corrosion and high winds presenting a severe test of any installation

Whether Professor Laithwaite's magnetic river system is superior to all others can only be judged when he produces enough technical data and hardware to justify his claims Even if it is, his problems will only then begin A high speed transport system cannot be developed on a domestic market A transeuropean system is likely to be German-French dictated Perhaps Sussex claims are not all that misplaced!

Time for a change?

Sir,—In *Nature*, Vol 250, August 30, 1974 was published a paper by Charles E Chaffey on a time-measuring system based on SI units Obscurantism for its own sake is admirably displayed in this paper The time-system postulated is unintelligible, having no frame of reference, and being unrelated to reality—days, lunar months and years, which exist on this planet in the absence of all arbitrary measurement

The author states that his aim is "the elimination of timers graduated in diverse units", presumably without regard to convenience or intelligibility The SI second, though defined differently, is still based upon day length divided by 24×60×60, therefore is irrational in terms of the decimal system (the division of the clock dial into 12 or 24 *is* rationally related to the geometry of the circle) Surely, if a so-called 'rational' system is to be adopted by scientists, then it should be the metric clock and the French Revolutionary Calendar (now being the last month of 182)

Incidentally, what is the starting point of C Chaffey's calendar? The Christian era? Surely not Why not Sir Isaac Newton's birthday? This would have the merit as being the same day as Christmas, and would remind all scientists of this great alchemist/astrologer/theologian who founded our new religion

Yours faithfully,
Nigel Pennick

Group papers

Sir,—Alan Mackay's proposal (*Nature* 250, 698, 1974) that papers should be published in the name of the research groups rather than of the individuals, deserves serious consideration in spite of his outdated references (to St Matthew and Church of England Articles) This procedure has in fact been encouraged in China The prime purpose of scientific communication is definitely better served by an improved standard, and decreased number, of publications (have you not read any recent issue of J Irreg Results?) No author or authors of any paper can claim exclusive credit for it why, otherwise should there always be acknowledgements? Under the new arrangement, individuals will still get the 'carrot' by belonging to a group which publishes a lot of good papers, and they won't miss the 'stick'

Yours faithfully,

Spectroscopy of organic molecules in solids

THE spectroscopist is interested in studying energy levels, the probabilities of transitions between levels, and the lifetimes of excited states Because of the low volatility of most organic compounds their spectra are normally observed by using solutions in a liquid or vitreous solvent The ultraviolet and visible absorption and emission spectra of solutions are, however, generally very broad and the structure that may arise from molecular vibrations is absent This loss of information can seriously reduce the value of observations of the electronic spectra of organic molecules

In a dilute vitreous solution, the interaction of a solute molecule with its local solvent environment perturbs the energy levels of the solute This interaction is different at different sites in the glass so the sample comprises a range of distinguishable solute molecules, the spectrum of such a sample is said to be 'inhomogeneously broadened' In a liquid solution, all solute molecules experience the same environmental influences (when an average is taken over the time that the molecule exists in the particular energy level) and the spectrum is 'homogeneously broadened'

The absorption spectrum of a glassy solution is broad, even at very low temperatures when the vibrational motion of the solvent is suppressed Its emission spectrum is also broad when the excitation is due to a broadband arc source The emission, or fluorescence, spectrum is caused by transitions from the lowest vibrational level of the electronically excited molecule to various vibrational levels of the ground electronic state (higher vibrational states of the electronically excited molecule generally decay very rapidly by non-radiative mechanisms to the lowest level, so the vibrations of the excited molecule are not normally seen in emission) Vibrational structure is not seen in such an emission spectrum if the variations in the energy-level differences due to site changes are larger than the vibrational spacings, and this is the usual situation for organic species

On page 215 of this issue of *Nature*, Eberly, McColgin, Kawaoka and Marchetti of the University of Rochester and the Eastman Kodak Research Laboratories in Rochester, New York, describe a method for obviating the effects of inhomogeneous broadening of the electronic spectra of organic solutes in vitreous solvents They employ a narrow-band laser source and observe vibrational structure in emission spectra Their success depends on the fact that only a small fraction of the solute sites in the glass is in resonance with the narrow-band source, leading to a selection of a particular class of solute molecules (those whose environments are sufficiently similar to let them absorb the incident radiation) Their technique is particularly effective when the incident radiation has the frequency corresponding to the energy difference of the lowest vibrational levels of the excited and ground states, the 0–0 band At higher frequencies, variations in the site may bring different vibrational levels of the electronically excited molecule into resonance Actually a number of ' extra" emission lines were seen from a 10^{-4}M solution of phenanthrene in a glass at 4 2 K when the incident frequency was 0 24 eV (1,900 cm^{-1}) above the centre of the 0–0 absorption band

The successful elimination of inhomogeneous broadening of the spectra of dilute solutions of organic molecules in glasses is reminiscent of the Lamb-dip, of a sharp form of two-photon absorption in the high-resolution spectroscopy of gases, and of the spin-echo experiment in nuclear magnetic resonance The Lamb-dip and sharp two-photon absorption may be seen in gases in intense radiation in a standing wave, when only those molecules with negligible velocity in the direction of propagation interact with both the forward and reflected beams, Doppler broadening is thus eliminated Hahn's spin-echoes arise through a reversal of the precession of magnetic moments through the application of a second pulse, the magnetic field inhomogeneities speed up or slow down both the forward and reverse precessions, leading to a coincidence, or 'echo', in the detector and the elimination of the broadening due to field inhomogeneities

The Rochester experements have yielded structure in the emission spectrum of naphthacene in a glass at 4 2 K This structure has been analysed to give vibrational frequencies of the molecule in its ground electronic state Though this is interesting and promising, and probably capable of wide application because of the availability of narrow-band tunable dye lasers, it should not be forgotten that these frequencies are easily obtainable from infrared and Raman spectroscopy DAVID BUCKINGHAM

Nude mice

SINCE their original description in 1966 (Flanagan, *Genet Res*, **8**, 295), nude mice have spread through the immunological world at a remarkable pace While mice heterozygous for the mutant nude gene (*nu*/+) are apparently normal, homozygotes (*nu*/*nu*) are hairless (hence their name) and have hypoplastic thymus glands (Pantelouris, *Nature*, **217**, 370, 1968) The thymus abnormality leads to a marked deficiency in thymus-derived (T) lymphocytes and nude mice are rapidly replacing thymectomised mice as models of T cell deprivation and as a source of relatively pure B lymphocytes for *in vitro* studies In many laboratories the *nu* gene is being back-crossed onto a variety of inbred backgrounds thereby increasing their usefulness for cell and tissue transfer experiments The T cell deficiency in nudes make them highly susceptible to infection (but apparently not to cancer) and they survive poorly in conventional animal houses Thus they are usually produced by mating heterozygotes

The extent of the T cell deficiency in nudes has remained controversial They are usually referred to as being 'congenitally athymic' but this is clearly a misnomer in view of the presence of a thymus gland in all nudes so far studied They have been shown to have T cell precursors which can repopulate a normal thymus (Wortis *et al*, *J exp Med*, **134**, 681, 1971) and develop into immunocompetent T lymphocytes (Kindred and Loor, *J exp Med*, **134**, 681, 1971) and several reports have suggested the possibility that small numbers of T cells are present in at least some nudes For example, approximately 1% of lymphoid cells in nude spleen and lymph nodes label directly with fluoresceinated alloantibodies directed against the θ (thy-1) alloantigen, a T cell marker in mice (Raff, *Nature*, **246**, 350, 1973) Although θ is expressed on some neural cells, epidermal cells, and fibroblasts, in addition to thymus and T lymphocytes, there is no evidence that it is found in readily detectable amounts on B lymphocytes, granulocytes, macrophages or other cells in lymphoid or haemopoietic tissues (Owen *et al*, *Nature*, **249**, 361, 1974) Thus it seems likely that these few θ^+ lymphoid cells in nudes are T lymphocytes, although their origin (host or maternal, thymic or extrathymic) and functional capabilities remain unclear

On page 229 of this issue of *Nature*, Loor and Roelants report the presence of another population of θ^+ cells in nude spleen which are distinguished from normal T lymphocytes (and those described previously in nudes) by having such small amounts of θ on their surface that they can be detected only by indirect immunofluorescence, particularly with an absorbed rabbit anti-mouse brain serum which appears to have anti-θ-like specificity These cells lack detectable surface immunoglobulin (a marker for B lmphocytes) and make up approximately 20% of nude spleen cells, but are present in very small numbers in nude lymph nodes and in lymphoid tissues of normal mice The identity of these cells is unknown and it seems premature to refer to them as T cells, which implies their migration from the thymus Loor and Roelants make the intriguing suggestion that these cells may be precursors of T cells, which perhaps have followed some aberrant differentiation pathway due to the lack of a normal thymus This is an attractive possibility in view of the recent evidence that one can induce the appearance of θ and other thymus alloantigens in cells lacking readily detectable amounts of these antigens by exposing them to a variety of substances (such as dibutyryl cyclic AMP and thymus extracts) for 1–2 h *in vitro* (Scheid *et al*, *J exp Med*, **138**, 1027, 1973)

Many pieces still are missing in the nude puzzle, the most important being the role of the presumptive wild-type protein in normal thymus and hair development The extent of the T cell deficit and the origin and nature of the θ^+ cells in nude lymphoid tissues may be answered, in part at least, by studying nude mice born in *nu*/*nu* parents, rather than of *nu*/+ parents as has been the case thus far Only in this way can the role of maternal and normal litter-mate T cells and thymus humoral factors on nude embryos be determined If such mice lack θ^+ cells in their lymphoid tissues it would establish once and for all the essential role of the normal thymus in their production

MARTIN C RAFF

When the ice age seemed to end

IN the opening years of this century a sequence of muds and clays exposed on the Island of Sjaeland, Denmark was described In two clay layers was an abundance of remains of the arctic alpine plant, *Dryas octopetala*, considered to be indicative of cold conditions The intervening mud contained remains of a more temperate flora including birch trees The sequence was thought to represent a climatic oscillation at the close of the last (Weichselian) glaciation, and the temperate interstadial was termed 'Allerød' after its site of origin Subsequently this sequence was found over a wide area of north-west Europe and the advent of radiocarbon dating has made it possible to assign tentative dates to the lithological boundaries West (in *Pleistocene Geology and Biology*, Longman, London, 1968) quotes the following values, which are averages of many dates

Older Dryas/Allerød Interstadial	11,950 b p
Allerød Interstadial/Younger Dryas	10,750 b p
Younger Dryas/Preboreal	10,250 b p

Further investigations in Denmark, however, led to complications in this basic scheme At Bøllingso a sequence was found in which the clays of the Older Dryas period were interrupted by a mud layer, indicating an interstadial predating the Allerød Similar sequences have now been found in Germany, Holland and Norway, and several radiocarbon dates are available Van der Hammen *et al* (*Geologie Mijnb*, **46**, 79, 1967) date the episode at 12,400-12,000 b p in the low countries, but a Norwegian date (Chanda, *Årbok Univ Bergen*, No 1, 1, 1965) places its openings at 12,650 b p In some British pollen diagrams there is evidence of a minor vegetational change in pre-Allerød times, for example at Haweswater (Oldfield, *New Phytol*, **59**, 192, 1960) and, more convincingly, at Tadcaster Yorks (Bartley, *ibid*, **61**, 277, 1962) but neither site has been radiocarbon dated

A kettlehole site, now beneath Blelham Bog near Windermere, was found to have two organic layers in its late Devensian (≡late Weichselian) sediments Pennington's pollen diagram (in *Studies in the Vegetational History of the British Isles*, edit by Walker and West Cambridge, 1970) of these layers shows a proportional increase in tree birch pollen during the lower organic layer, but the radiocarbon date obtained (14,330±230 b p) is considerably older than the classic Bølling interstadial Subsequently Pennington and Bonny (*Nature*, **226**, 871, 1970) have confirmed the dating of this layer with a further date of 14,280±230 b p and have also clarified the vegetational events of this period by means of absolute pollen sedimentation determinations (see Davis and Deevey, *Science*, **145**, 1293, 1964) They found that the pollen input rate of the lower organic layer was similar to that in the adjacent clays, the apparent rise in birch pollen was a statistical artefact resulting from the use of proportional expressions Thus in Britain there is still no well authenticated and dated interstadial equivalent to the continental Bølling which is separable and distinct from the subsequent Allerød interstadial Bartley's Tadcaster site remains the most hopeful contender

At Colney Heath in Hertfordshire there is a peat which may have been transported by a glacier and buried in detritus Godwin (*Proc R Soc*, **B150**, 258, 1964) described an arctic flora from this peat and dated it at 13,560±210 b p This material thus postdates the Blelham lower organic layer, but gives no indication of an improvement in climate

Datings of the opening of the supposed Allerød interstadial have usually depended upon lithological changes, in particular the replacement of minerogenic sediments by organic ones Early dates of this boundary showed considerable consistency and were also in close agreement with continental dates Godwin and Willis (*Proc R Soc*, **B150**, 199, 1959) quote such dates as 11,942±120 b p (Lunds, Yorks), 11,880±225 b p (Keith, Banffs) and 11,870±120 b p (Windermere) Subsequent dates have not shown this degree of consistency, for example at Loch Droma, Ross and Cromarty, a date of 12,810±155 b p was obtained (Kirk and Godwin, *Trans R Soc Edinb*, **65**, 225, 1965) This date was very difficult to explain since it predated even the Bølling and yet gave all indications, lithological and palynological, of being the commencement of the Allerød Other similar dates have now been obtained from a variety of sites, particularly in Scotland Bishop (*Trans J Proc Dumfries Galloway nat Hist Antiq Soc*, **40**, 117, 1963) gave a date of 12,940±250 b p to the opening of the interstadial at Lockerbie, Dumfries, Sissons and Walker (*Nature*, **249**, 822, 1974) give dates of 12,750±120 b p for kettle hole deposits near Callander, Perth, and 11,290±165 and 13,151±390 b p for Loch Etteridge in the Grampians of Scotland At the latter site, the younger date corresponds to the commencement of gyttja sedimentation and the older date refers to the underlying clay gyttja Pennington and Bonny date the climatic improvement (as evidenced by a considerable increase in absolute pollen influx) in Blelham Bog at between 12,700 and 12,950 b p Simpkins (*New Phytol*, **73**, 605, 1974) has recently published a date of 12,050±250 b p for the base of organic sediments from a kettlehole at Glanllynnau, North Wales, but Coope and Brophy (*Boreas,* **1,** 97, 1972) have obtained a date of 12,556±230 b p for the same layer using only the macrofossil fruits of cyperaceous plants for the dating and thus avoiding contamination from penetrating roots At Glanllynnau, the basal organic sediments contain little tree birch pollen, the expansion of this constituent occurring 10 cm above the clay/gyttja transition Juniper pollen is poorly represented throughout, but there is a trace of expansion within these basal layers An analysis of the fossil Coleoptera of this site by Coope and Brophy gave evidence of climatic improvement well below the lithostratigraphic change, at 12,850±250 b p This improvement was reflected neither in the lithology nor in the relative proportions of the pollen assemblage at that level

This collection of dates and observations is leading some researchers, particularly Pennington, to propose that some of the lithological and biological changes which have been taken to represent the commencement of the Allerød interstadial, *sensu stricto,* are in fact indicative of the climatic amelioration which gave rise to the Bølling sediments on the continental mainland Climatic improvement may have begun by 13,000 b p but lithological changes in some sites was delayed for a thousand years In Britain the two interstadials seem to have run into one, particularly in the northern and western parts of the islands Presumably the oceanicity of the British Isles has influenced the degree to which climatic thesholds have been successively crossed, as a result, the response of the biota and any fluctuations in the nature of sedimentation have been dampened in the amplitude of their oscillations It would seem that the search for a Bølling in the west of Britain is at an end

Faunal evidence for a decline in temperature during the interstadial has been found as early as 12,000 b p by Coope *et al* (*Palaeogeogr Palaeclimatol Palaeoecol*, **10,** 87, 1971) Lithological evidence for the close of the interstadial and the onset of solifluction is dated 10,828±185 b p at Scaleby (Godwin, Walker and Willis, *Proc R Soc*, **B147,** 352, 1957) and at Loch Etteridge, Sissons and Walker obtained a date of 10,765±120 b p The final close of the Allerød thus seems to be a well marked occurrence, the date of which may vary slightly from one locality to another dependent on local conditions such as relief

The end of the cold Younger Dryas period was dated by Godwin *et al* to 10,257±350 b p at Scaleby Moss, but there is a problem of lithological and biological definitions of this boundary At Scaleby the date refers to the first rise in the proportion of juniper pollen Some other dates for this change are 10,490±160 (Blelham, Pennington and Bonny), 9,590±170 (Bigholm Burn, Dumfries, Moar, *New Phytol*, **68,** 433, 1969) 9,508±200 (Red Moss, Lancs, Hibbert *et al*, *Proc R Soc* **B177,** 161, 1970) and 9,660±105 (Slieve Gallion, Co Tyrone, Pilcher, *New Phytol*, **72,** 681, 1973) As Smith and Pilcher (*New Phytol*, **72,** 903, 1973) have pointed out, this biologically defined horizon is evidently diachronous within the British Isles The use of lithological features (that is, the replacement of clay by primarily organic sediments) is equally variable, however Birks (in *Past and Present Vegetation of the Isle of Skye,* Cambridge, 1973) gives dates of 9,420±150, 9,482±150 and 9,655±150 b p for the base of Flandrian muds in Skye Sissions and Walker also have a late date, 9,405±260 b p for a similar horizon at Loch Etteridge Evidently the conditions necessary for lithological change were satisfied at different times in different parts of the country, depending upon local climate, relief, geology and so on The definition and dating of the close of the late-Devensian period and the opening of the Flandrian thus remain rather obscure

With the increasing number of radiocarbon dates and biological and lithological analyses of late-Devensian deposits in Britain, the complex underlying climatic changes within this unstable period are beginning to be understood It is becoming clear that simple threefold division of the period is a gross and rather misleading misrepresentation of the diverse temporal and spatial conditions found in the British late-Devensian PETER D MOORE

New Miocene polarity scale

from Peter J Smith

THE statistical analysis of geomagnetic field reversals, begun by Cox (*J geophys Res*, **73,** 3247, 1968) and later developed further by Blakely and Cox (see, for example, *J geophys Res*, **77,** 4339, 1972), seems a complicated business to non-mathematicians Fortunately however, most of the conclusions emerging from it are relatively easy to understand and offer an interesting example of the predictive power of statistics where a data set is incomplete and likely to remain so for some time The problem with the data set in this case is that, although relatively long periods of single polarity may be detected and measured with reasonable accuracy, the lengths of very short polarity intervals lie within the errors of the dating technique This, coupled with the fact that short intervals are intrinsically unlikely to be represented by very many magnetised rock samples, makes it difficult to investigate experimentally any variations in field behaviour (for example, reversal frequency) with time

Previous statistical work on the geomagnetic time scale has indicated that field reversals apparently ocurred randomly throughout the Cainozoic and may be described by a Poisson probability model with an average reversal frequency λ But λ seems to vary with time, most markedly during the Miocene The frequency of known reversals over the past 45 million years (Myr), for example, was 3 0 Myr^{-1}, whereas the period 22 7–7 3 million years ago had an anomalously low average reversal frequency of 2 5 Myr^{-1} So the question is did the reversal rate really decrease over this limited period, or do other reversals (probably linked with short polarity events) remain to be discovered?

To find out, Blakely (*J geophys Res*, **79,** 2979, 1974) has analysed 18 total field profiles from the north-east Pacific, the east Pacific rise and the Indian–Antarctic ridge using the signal-averaging technique previously developed by Blakely and Cox, a technique by which profiles are combined and normalised to a common average spreading rate Among the important results to emerge or follow from this analysis are the following

A comparison of the combined (stacked) profile from 14 north-east Pacific profiles with a computer-generated model profile from the time scale of Heirtzler *et al* (*J geophys Res*, **73,** 2119, 1968) shows that for the period 22 7–7 3 Myr there are eight short-wavelength magnetic anomalies present which are not predicted by the previously published time scale In particular, anomaly 5, originally thought to be a single constant polarity epoch lasting for 1 15 Myr, is now seen to comprise five short-wavelength anomalies, thus confirming the result of Cande and Labrecque (*Nature,* **247,** 26, 1974) Additional data from four east Pacific rise and Indian–Antarctic ridge profiles (areas distant from the north-east Pacific) confirm the presence of the eight extra anomalies on a worldwide basis

A plot of average spreading rate for the 14 principal profiles taken together (constructed from data obtained incidentally in the main analysis) suggests that the rate varied often, and often quite violently, over the period 22 1–7 6 Myr ago Between 19 3 and 18 5 Myr ago, for example, the spreading rate apparently decreased from 47 7 mm yr^{-1} to 21 8 mm yr^{-1}—a surprising deceleration within only 0 8 Myr Apparent spreading rates for the other two areas of study taken separately fluctuate with time in a similar manner, implying further that spreading rates were changing coherently throughout the world The face-value interpretation of these results is that, during the Miocene, seafloor spreading did indeed proceed discontinuously

There is another possible explanation, however The basis of comparison used by Blakely in his analysis was the time scale of Heirtzler *et al*, a scale which assumes that seafloor spreading was constant at the mid-Atlantic ridge during the Cainozoic and which used the single magnetic profile from Vema cruise 20 in the South Atlantic But this interpretation may not be valid If, instead, it is assumed that the Pacific, Indian and Antarctic plates were each moving uniformly during the Miocene, then the Heirtzler scale must be adjusted For various reasons (for example, that accelerations of entire plates relative to the asthenosphere would have had to have been improbably high at 20 km Myr^{-2} or even 40 km Myr^{-2}) Blakely concludes that such uniformity is likely, or at least the most likely situation given current data As Blakely points out, although many examples of variable spreading rates have been described by other workers, most are from localised areas and do not include evidence for variations synchronised on several plates The assumption of zero acceleration for plates is thus the simplest, but still "tenuous at best"

Nevertheless, using this assumption Blakely goes on to construct a new Miocene time scale which adds 18 reversals to the Heirtzler time scale for the period 22 7–7 6 Myr Sixteen of these reversals are derived from the eight short-wavelength anomalies, and the remaining two are obtained by dividing the positive interval at 13 Myr on the Heirtzler scale into two smaller positive events The revised scale now contains 14 short events lasting less than 0 1 Myr It also has an average reversal frequency of 3 7 Myr^{-1}, which is a significant increase on the previous 2 5 Myr^{-1} At the same time, the new figure is higher than the 3 0 Myr^{-1} rate derived from known reversals over the past 45 Myr, which suggests that there may also be some undetected events outside the more limited Miocene period considered by Blakely

Finally, by comparing magnetic profiles for crustal magnetisation models with real profiles, Blakely is able to estimate the width of the transition zones from one polarity to the other In each of the three models concerned the magnetised crust is regarded as a 0 5 km thick horizontal slab with its upper boundary at a depth of 3 5 km, but the models differ in the width of the band about the spreading centre over which new crust becomes magnetised The best fit to the data from the north-east Pacific is obtained for a model in which the transition between polarities takes place over a horizontal distance of 6 km This figure is, however, highly dependent on the thickness of the magnetic layer, for a layer thicker than 0 5 km, 6 km would be an overestimate

Anti-actin

from Dennis Bray

THE rumour that antibodies cannot be produced against actin lasted about five years Born of one or two unsuccessful attempts to raise antisera to this major protein of muscle, the rumour was nurtured by a familiar process of *post hoc* rationalisation Actin is non-antigenic it was said, because it has such a strongly conserved structure that the small differences between species are not able to provoke an immune response Actin is non-antigenic because it is present in almost every cell of the body so that all animals will have innately acquired tolerance Anybody thus dissuaded from an attempt to make this most useful antiserum, however, has cause for regret For there are now three independent reports of its production

The starting point for two of the reports was the observation that patients with certain aggressive forms of hepatitis have autoimmune antibodies in their circulation Although it was known from work with fluorescent antibodies that these were directed against smooth muscle, the precise nature of the antigens was not known Gabbiani and colleagues (*Am J Path*, **72**, 473–488, 1973) have now examined this by absorption studies and have found that this serum cross reacts with the actomyosin of blood platelets and with the purified component known in platelet circles as thrombosthenin A, but elsewhere simply as actin Concluding from their tests that the serum is essentially anti-actin, the authors used it in immunofluorescent tests to show the distribution of this protein Many non-muscular tissues, including liver cells, brush borders and intestinal epithelial cells, were found to be specifically stained

Stimulated by the same medical findings, and in the laboratory in which they were originally made, Trenchev and colleagues (*Clin exp Immun*, **16**, 125–136, 1974), sought to compare the autoimmune sera with those against various protein components of human smooth muscle These were prepared by conventional methods against muscle myosin, tropomyosin and actin, and used in immunofluorescent tests Once again a constellation of tissues were stained and a correlation between staining and the presence of microfilament arrays was noted, as in the networks of stained filaments seen in HeLa cells The different types of artificially induced antibodies gave slightly different staining patterns but none seemed to resemble the hepatic sera more closely than the others

Quite a different method and a highly original one was used by Lazarides and Weber (*Proc natn Acad Sci USA*, **71**, 2268–2272, 1974) Rather than prepare antisera to conventionally prepared actin, with its persistent complement of other proteins such as tropomyosin, these authors used the bold and very direct approach of injecting material recovered from SDS (sodium dodecyl sulphate) gels The source of their material, mouse fibroblasts, is rich in actin and even a crude fractionation is adequate to give a band on acrylamide gels which is fairly pure The denatured protein extracted from the gels is apparently a potent antigen and able to induce antibodies which cross react with both fibroblast and muscle actin When used to stain the fibroblasts by the indirect fluorescent method this serum gave striking results Brightly stained filaments in a wide variety of patterns are seen, sometimes aligned in parallel with the long axis of the cell or close to the outer surface, at other times arranged radially around central focal points

Taken together these three reports provide good evidence that antibodies to actin can be produced, although the legally minded will not be without reservations In not every case was the purity of the actin adequately monitored—a boring point but important in the light of previous experience—nor were all of the immunological controls carried out Surprisingly, not one of the antisera was tested against adult skeletal myofibrils which surely would give a direct test of their specificity And the use of antisera to denatured proteins is an uncertain business which, again to invoke rumours, may not have such a high degree of specificity as one is used to with native proteins

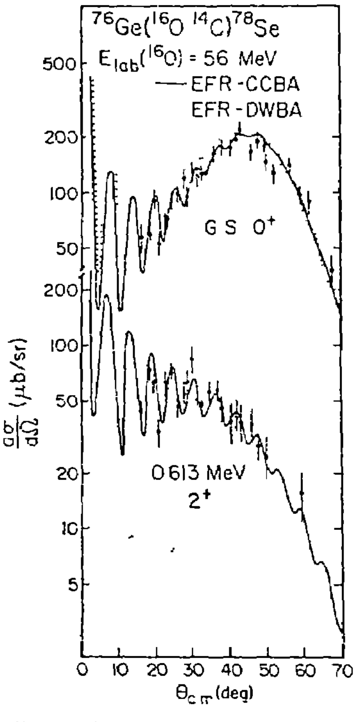
But these are quibbles which will no doubt be resolved in time In general the results are most encouraging, both from a medical point of view as well as that of cell biology The technique of Lazarides and Weber, using the combination of immunofluorescence and SDS gels would seem to be of particular potency One of its strengths is its applicability to structural proteins normally classed as insoluble and almost the first question about such proteins is where are they in the cell? Electron microscopy can give some indication, but is limited in its ability to identify different chemical types and in the area of the cell which it can cover Methods involving antisera and the light microscope are potentially free of both of these restrictions

Two-nucleon transfer between heavy ions

from P E Hodgson

THE theoretical analysis of reactions between heavy ions in which two nucleons are transferred from the projectile to the target has now been developed to a high degree of sophistication The basic distorted wave theory was formulated many years ago and successfully applied to analyse (d,p) reactions But in the case of heavy ion reactions many of the approximations that are made for (d,p) reactions are no longer valid, in particular the use of a zero-range interaction and the neglect of recoil Inclusion of these effects is very complicated and greatly increases the computation time Furthermore it has become increasingly clear that in many transfer reactions involving collective nuclei the contributions from two-step processes that take place through the pre-excitation of the target nucleus or by post-excitation of the residual nucleus must also be included Lastly in heavy ion reactions there are substantial contributions from a large range of incident orbital angular momenta

All these factors have combined to make the whole calculation prohibitively long, even on the fastest computer, if it is carried out in the usual way Recently, however, Low and Tamura (*Phys Lett*, **48B**, 285, 1974) have developed new techniques for evaluating the multidimensional integrals that occur in these calculations, and these have so strikingly reduced the computing time that these calculations are now practicable



Differential cross section for the two-proton transfer reaction $^{76}Ge(^{16}O,^{14}C)^{78}Se$ to the ground and 2^+ excited state of ^{78}Se compared with exact finite range calculations The dotted line shows the one-step distorted wave calculation (EFR-DWBA) and the full line shows the coupled channels calculation (EFR-CCBA) that takes into account the contributions of two-step processes in the exit channel

These new computing techniques have been applied by Tamura, Low and Udagawa (*Phys Lett*, **51B**, 116, 1974) to calculate the cross section for the two nucleon transfer reaction $^{76}Ge(^{16}O,^{14}C)^{78}Se$ to the ground and first excited (2^+) state of the final nucleus Comparison with the measurements of Lemaire, Mermaz, Sztark and Cunsolo shows that the distorted wave calculations are inadequate, even when finite range effects are taken into account (see dotted line in figure) The cross section for the reaction to the ground state shows too much oscillation and is too high at small angles, while that of the reaction to the 2^+ state at 0 613 MeV is far too small

They then took into account the inelastic excitation in the exit channel The residual nucleus ^{78}Se is easily excited into low-lying collective states, so it is possible for the two transferred nucleons to be first added to the target to give ^{78}Se in its ground state, and then for the outgoing ^{14}C nucleus to interact again and excite the ^{78}Se nucleus to the 2^+ state This two-step contribution to the reaction adds to the direct contribution when the two nucleons are transferred so as to produce the ^{78}Se nucleus immediately in its 2^+ state There is also a small effect on the cross section of the reaction to the ground state, for this similarly has a two-step component that goes first to the 2^+ state, which is then de-excited by inelastic scattering in the exit channel

This complicated calculation can be carried out without any adjustment of parameters The wave function of the two transferred protons to be added to the target was obtained using the standard Bardeen–Cooper–Schreiffer method with the Random Phase Approximation The single-particle energies were taken from previous work and the strength of the pairing interaction was determined by fitting the experimental separation energy The separation of the two protons from the ^{16}O was calculated using the fractional parentage coefficients of Cohen and Kurath

The results of this calculation, taking the two-step processes in the exit channel into account, are shown by the full line in the figure The agreement is excellent, indicating that the essential physics of the process is now well understood In particular, it is clear why the inclusion of the two-step processes produces such a dramatic improvement Since the ^{78}Se and ^{76}Ge nuclei are both superconducting, the transition from the ground state of the target to the ground state of the final nucleus is much stronger than the transition to the first excited state Thus inclusion of the two-step process greatly enhances the 2^+ cross section but has a much smaller, though still important, effect on the reaction to the ground state

There are still more effects that could be taken into account, in particular the inelastic effects in the entrance channel In the calculation of the form factor of the transferred protons only the most important term, corresponding to 0s relative motion of the two protons, was taken into account, and a fuller calculation could investigate the contribution of the higher order terms Nevertheless, the success of the present calculations suggests that the most important effects have already been included, and that these improvements will not substantially affect the detailed understanding of this reaction that has now been achieved

Gels and chains

from a Correspondent

IT has been known, since the work of the Singers and of Allison in the 1950s, that gel formation in solutions of deoxy sickle-cell haemoglobin (Hb–S) is highly dependent on Hb–S concentration and that the minimum gelling concentration (MGC) is a function of temperature, *p*H, ionic strength and the presence of organic phosphates which bind preferentially to deoxy β-chains More recent studies by Bookchin, Nagel and Ranney on mixtures of deoxy Hb–S with other haemoglobins showed that the MGC values were higher, but that the partial concentrations of Hb–S at gelation were lower, indicating the incorporation of other haemoglobin species in the gel Following an earlier analysis of these results by Minton on the basis of a two-step aggregation process, they have now been re-interpreted by Moffat (*Science*, **185**, 274, 1974), assuming the formation of hybrid tetramers formed by association of unlike dimers in such binary mixtures, for example $\alpha^{A}{}_{2}\beta^{A}\beta^{S}$ from $\alpha^{A}\beta^{A}$ and $\alpha^{A}\beta^{S}$ in a mixture of Hb–S and normal adult Hb–A

According to Moffat all possible tetramer species are in principle capable of incorporation into the gel the gel forms when the weighted sum of their concentrations reaches a critical value, the MGC for pure deoxy Hb–S under the same conditions, which is assigned a weight of unity. The weights (w) can be regarded as relative association coefficients for the addition of particular tetramer species, hybrid or symmetrical, and deoxy or liganded, to the haemoglobin polymer. Since, however, deoxy tetramers have extremely small dissociation rate constants, hybrid formation is rapid in mixtures in the oxy form (as used by Bookchin and coworkers), and subsequent deoxygenation effectively freezes the resulting equilibrium mixture of tetramer species. From the value of the identical dissociation constant found for separate and mixed oxy Hb–A and Hb–S, Moffat evaluated individual tetramer concentrations and hence derived weighting coefficients for the tetramer components of the mixtures under consideration. The structural implications of these weights are clearly complex, and no clearcut generalisations emerge. For deoxy foetal haemoglobin (Hb–F) w is about 0.1, a result of some clinical interest in view of the proportions of Hb–F found associated with Hb–S in some clinical conditions. The weights do not depend greatly on the ligation state of the non-S chains, for example deoxy Hb–A and cyanmet Hb–A both have weights of about 0.5. The high w values for hybrid tetramers are also noteworthy. From the w values for deoxy Hb–A and deoxy Hb–S Moffat predicted that mixing in the deoxy form, with no hybrids present, would result in a higher MGC than mixing in the oxy form, facilitating hybridisation, followed by deoxygenation. This prediction was confirmed experimentally over a wide range of fractional composition. Moffat regards gelation as a highly cooperative process in contrast to Minton, who envisaged a two-step model in which linear polymerisation of haemoglobin tetramers into filaments is followed by lateral aggregation of the filament to form the gel.

An explanation at the molecular level for the depression of α or β chain biosynthesis in the respective thalassaemic states must be looked for by the study of gene expression and protein synthesis. Some progress has been made in elucidating the molecular basis of two forms of α-thalassaemia. Clegg and Weatherall (*Lancet*, ii, 133, 1974) now suggest that increasing circumstantial evidence for the relative instability of the messenger RNAs coding for the δ-chain of human Hb–A$_2$, and for the various $\delta\beta$ (Lepore) and $\beta\delta$ (anti-Lepore) chains, may be relevant to the molecular defect in some β-thalassaemias. Both Nance and Stamatoyannopoulos and coworkers have previously considered the possible role of fusion genes, of the Lepore type, in β-thalassaemia. Clegg and Weatherall now suggest that B^0 thalassaemia, in which there seems to be total absence of β chains, may be associated with a δ-like pattern of β-chain synthesis. In Nance's model this would involve silent Lepore-type fusion genes coding for normal β-chains, but controlled like a δ-chain gene. Clegg and Weatherall suggest that the instability of δ-chain mRNA is due to loss of stabilising regions at the 5′ and 3′ ends, subsequent to the evolutionary divergence of the β and δ chain genes. They discuss possible tests of their hypothesis, one of which would be the detection of small proportions, say 1%, of Hb–A in untransfused homozygotes for β-thalassaemia, containing normal β-chains but formed only in early nucleated erythroid precursors by the unstable mRNA.

Photographing a superfluid vortex

from P. V. E. McClintock

IT has long been realised that superfluid helium cannot rotate bodily: it is believed that, instead, rotation of the container may result in the formation of one or more individual quantised vortex lines. Particular interest therefore attaches to a report by Williams and Packard of the University of California at Berkeley in a recent issue of *Physical Review Letters* (**33**, 280, 1974) that they have been successful in obtaining photographs apparently showing for the first time the positions of individual vortex lines in superfluid ^{4}He.

The linear vortex, a classical phenomenon which was investigated in great detail by Lord Kelvin, consists of a cylindrical core which may or may not be hollow and, surrounding it, rotating fluid whose tangential velocity v_s is inversely proportional to the distance from the centre of the core. The vortex which forms above the plug hole as water flows out of a bath is a familiar example of a hollow cored vortex.

Vortices in superfluid helium are, however, of special interest because they are quantised: the quantity $\int v_s \, dl$, evaluated around any closed loop in the superfluid and known as the circulation, is always equal to $n(h/m)$ where h is Planck's constant, m is the mass of helium atom, and n may be zero (no vortex core present inside the loop) or a positive integer. The flow of superfluid around the core can be described by a macroscopic wave function and occurs without dissipation of energy, much like an electron in a stable state around the nucleus of an atom, so that the existence of quantised vortices may be regarded as a macroscopic manifestation of quantum mechanics.

Thus, when a container of superfluid, initially at rest, is rotated sufficiently slowly, the superfluid will always remain at rest relative to the fixed stars, no matter how long the experiment is continued. If the angular velocity is increased it will, however, eventually become energetically favourable for one or more vortex lines to be created in the liquid. At large rotational speeds many vortex lines are present and the resultant motion of the liquid approximates to solid body rotation at the same angular velocity as that of the container. It had been widely assumed that the vortex cores which in helium are approximately of atomic dimensions, would all be arranged parallel to the axis of rotation and spaced in a triangular lattice relative to each other. But despite extensive experimental evidence both for the existence of vortex lines and also for their quantisation, nobody had previously been able to determine experimentally their actual positions and orientations in the container, and it is this which Williams and Packard have now accomplished.

In essence their technique was extremely simple and exploited the fact that when free electrons are injected into liquid helium they form relatively large bubble-like structures of radius about 16 Å. These negative ions, by virtue of the reduction in energy arising from the excluded rotating superfluid, are very strongly attracted towards the core of a vortex. Thus, by using a radioactive electron source and a suitable arrangement of electric fields, it was possible to charge the array of vortices inside a rotating container of superfluid helium so that each vortex had negative ions spaced out at intervals along its core, rather like a string of beads. Then, by an appropriate reversal of electric field, the ions could all be shot off the vortex lines and out through the surface of the liquid. By positioning a scintillator above the surface it was possible to ensure that the current pulse arising from each vortex line would give rise to a spatially separate flash of light, thus indicating the position of that vortex in the liquid.

In practice, despite its apparent simplicity, the experiment has proved to be considerably more difficult than was the equivalent experiment to demonstrate the lattice of vortices in a superconductor. To achieve their successful result, the authors had to perform the not inconsiderable technical feat of mounting a complete ^{3}He–^{4}He dilution refrigerator, capable of reaching temperatures below 0.1 K, on a rotating table, it had been necessary to add a small proportion of ^{3}He to the superfluid ^{4}He in order to stabilise the vortex array, a magnetic field was required to focus the pulses of electrons leaving the liquid, and a very high quality optical system, using fibre optics to bring the feeble flashes of light up from the cold end to an image intensifier at room temperature, had to be developed The light from the image intensifier passed into a wide aperture camera loaded with high speed film

It was found that, with the apparatus in rotation, a series of spots did indeed appear on the film whereas, at rest, a completely blank negative resulted The density of spots was roughly equal to the expected density of vortex lines in the liquid, and was proportional to the angular velocity

It turned out, however, that the vortex lines were not in fact arranged in a regular manner, and moreover they appeared to wander around in the liquid in a random manner The reason for this is not yet clear but, now that a successful technique for photographing individual vortex lines has been developed, the topic will no doubt be the subject of further theoretical and experimental investigations

Control sites in the lactose operon

from Benjamin Lewin

THE lactose operon has been subjected to such intensive genetic analysis during the past decade that it is perhaps surprising that not all possible classes of mutant were isolated long ago That the mutants initially taken to identify the promoter in fact correspond to impairment in the action of the cyclic AMP system is, of course now well known The wild type lactose operon can be expressed at its full level only in the presence of the cyclic AMP receptor protein (CRP), activated by cyclic AMP The mutants previously isolated which reduce to 2% of its wild type maximum the expression of the lactose operon all map at the left end of the region between *lacI* and *lacO*, since they fail to recombine with the L1 deletion that covers this region, the reduction to 2% maximum expression is shown also by cells which contain a wild type lactose operon but lack a functional cyclic AMP system The far left end of the lactose control region therefore seems to provide a DNA site which is necessary for the interaction of CRP and RNA polymerase Mutants located between this site and the operator have been isolated which allow a high degree of operon expression in the absence of the cyclic AMP system, presumably by creating a site which allows the RNA polymerase alone to initiate transcription

The model accepted to explain these results supposes that the promoter of the lactose operon is a complex structure, its left end providing for an interaction with the CRP and its right end providing the site where RNA polymerase binds and initiates transcription How the interactions at these sites are related is not clear A prediction of this model is that mutants which reduce the level of expression of the operon by lowering the affinity for RNA polymerase of its binding site should map at the right end of the promoter region

The isolation of these mutants, constituting the first new mutant class to be reported for some time in the lactose operon, has now been accomplished by Hopkins (*J molec Biol*, **87**, 715–724, 1974) Certain repressor mutants share with promoter mutants the phenotype of reduction in maximum operon expression since they prevent induction, but the promoter mutants alone reduce the basal level of lactose enzymes in the uninduced cell Using this distinction to identify promoter mutants, Hopkins isolated two classes, the first comprise the previously identified kind of mutation at the left end of the promoter and show failure to respond to the cyclic AMP system, the second class, isolated for the first time, are located at the right end of the promoter region as shown by their ability to recombine with the L1 deletion, and have the properties expected of mutants altered in the interaction with RNA ploymerase—they show about 6% of wild type expression in cells with an active cyclic AMP system and this level is reduced to less than 0 5% when the cyclic AMP system is inactive (wild type operons show 2% expression in the absence of the cyclic AMP system) All three mutations of this type lie between the right end of L1 and the operator The isolation of these mutants opens the possibility of analysis *in vitro* to determine exactly which stage of action of RNA polymerase is inhibited, clearly the next step in identifying the action of this part of the promoter

The binding of repressor protein to the lactose operon, hitherto thought to implicate only the operator site immediately to the left of the *lacZ* structural gene also may involve more than one site Using a competitive binding assay for repressor, in which the DNA to be tested is mixed with repressor in the presence of a standard (labelled) operon and the reduction in retention of label on filters is measured, Reznikoff, Winter and Hurley (*Proc natn Acad Sci USA*, **71**, 2314–2318, 1974) confirm that deletions of the lactose operon have no affinity for repressor and constitutive operator mutants have a reduced affinity depending on the mutation Promoter mutants show no reduction in repressor binding, including one deletion which appears to remove virtually all the promotor though leaving the operator intact, the independence of these two sites contrasts strongly, of course, with the overlap between them which is seen in phage lambda A deletion which removes *lacZ* but does not extend into the operator has the same affinity for repressor as wild type lac DNA, confirming that the operator does not extend into the structural gene

But the strong *lacO*^{c} mutant DNAs have a much greater affinity for repressor *in vitro* than would be expected from the effect of these mutations in the cell, two mutants which reduce the induction of lactose enzymes in the cell by 100 and 300 times show a reduction in affinity for lactose repressor of only 25 or 30 times And deletions which remove a large part of the operator show the same affinity for repressor as the operator-constitutive point mutations This suggests that some common residual binding of repressor might take place at a site present in all these mutant DNAs When these deletions extend into the first part of the *lacZ* gene, the residual binding remains, but when they extend further, the affinity for repressor is much lowered This suggests that a secondary binding site is present in the *lacZ* gene, some distance from the operator but within the first thousand bases

Since the operator seems to be at least 16 bases long, it is very unlikely that this second binding site might be the result of a coincidence of sequence, the probability of independent origin of a sequence with an affinity for repressor as great as 3-4% of that of the operator is low—some *lacO*^{c} point mutations might well show this order of binding No obvious role can yet be seen for this second binding site, although it is possible that it might act as a failsafe signal for blocking progress of polymerases that have passed the operator or that it might interact in some secondary structure with the primary operator, there is, however, some evidence from earlier work to argue against both these possible models The evolutionary origin of this site is an interesting question, some light on which may be cast by sequence studies of the *lacZ* gene as well as the control region If the second site does play some part in operon function, then its nucleotide sequence must be under two sets of selective constraints, one concerned with its binding of repressor and one with the amino acid sequence specified in β-galactosidase

Radiation effects in the fusion power programme

Andrew Holmes-Siedle

J J Thomson Physical Laboratory, University of Reading, Whiteknights, Reading RG6 2AF, UK

As the prospect of a commercial fusion reactor becomes more real, concerted research is needed into the damage that is likely to be caused by radiation during its lifetime

In the past few years, our confidence that we can produce power from controlled thermonuclear fusion has grown, while we have also become more aware of the benefits of fusion power with respect to economy of resources and relative levels of pollution[1,2] As a result, the already large international fusion research effort is about to take another step and we are beginning to study the more practical aspects of economics and the detailed technological needs of controlled thermonuclear reactors (CTRs) This new character of the research is prompted by the high measure of confidence among plasma physicists that the necessary levels of plasma temperature, confinement time and density can be achieved so that a net power gain is achieved from fusion reactions Without fully understanding the plasma behaviour, they believe that, by scaling the plasma confinement system up in size, the conditions for the thermonuclear fusion can be achieved The choice of reactant will, however, be limited initially to the well known DT system

$$D+T\rightarrow {}^{4}\mathrm{He}\ (3\ 5\ \mathrm{MeV})+n\ (14\ 1\ \mathrm{MeV})$$

Since tritium is not available naturally, it must be bred within the reactor and the only likely reactions available are those of neutrons with lithium

With these two basic features in mind, some design features of a suitable CTR can already be discerned Studies of several different forms are under way[3,4] and preparations are being made to test the feasibility of large scale power production, with the aim of proving the case by the end of the decade[2] Given a positive answer, then the fusion programme would shift to a phase of developing large, efficient CTRs Those carrying out design studies are unanimous that we will need to build up a considerable body of new technological skills in order to build such a machine This article describes the research work which is going on in one particular facet of those skills—radiation effects—and, by outlining the extent of the radiation problems in the CTR, attempts to justify the contention that a lot of research and development remains to be done Similar treatments could be developed for other areas of CTR technology, a basic list of which is given in Table 1

Much of the fusion reactor technology can be discussed independently of the form of confinement used, and this is particularly true of the extensive damage and excitation effects which will occur in the confinement system surrounding the reacting plasma and the basic approaches to understanding and dealing with them We know, for example, that most of the fusion energy released will reside in the neutrons and that, as a result, the materials of the confinement vessel will be severely damaged by these neutrons and accompanying ionising radiation, while the levels of mechanical stress and temperature will also be high Radiation and other stress levels have been worked out for some reference designs and I shall draw heavily on the data for two of these, namely the United Kingdom Tokamak design and the Reference Theta-Pinch Reactor (RTPR) designed in the United States[5]

This arbitrarily chosen pair of reactors represent two divergent approaches to a power-producing toroidal reactor of which the engineering design is quite well developed Figure 1*b* shows a cross section of the RTPR and demonstrates the complexity of structure contemplated even in the concept stage It real life, the simple concentric layers will, of course, be interrupted by ducts and cables leading out from the plasma The coils for this design are not superconducting Figure 1*a* shows a segment of the United Kingdom Tokamak, with some speculative additions by myself to the concept of Mitchell and George[6] The neutron fluence values noted are not speculative, however, but derive from the neutronics and shielding calculations of McCracken and Blow[7], however, they are 'worst case' values for a first-wall energy flux value of 10 MW m^{-2} when, in fact, a wall loading value one tenth of this may be adopted It should be noted that, in both designs, a considerable neutron fluence emerges from the toroid and, if equipment is to be placed within the biological shield, a wide variety of electronic components could receive significant irradiation[8]

Figure 2 shows calculations of the irradiation rates for the two reactors[7,9] Gamma rays are generated by interaction of the neutrons with the structural materials To the materials scientist, these radiation levels seem unpleasantly large, although not much greater than those experienced near the core of a fission reactor In the CTR, however, the demands on components and materials are greater in that a high-vacuum chamber, powerful magnets and numerous other complicated systems have to be operated in this environment, as well as the coolant system The presence of a wider variety of high performance components is likely to compound the problem considerably Before discussing these specific effects, however, I shall make some general remarks concerning radiation effects at the high levels expected

Damage phenomena

The permanent effects of radiation can be divided into two main classes damage distributed throughout a material ('bulk damage') and damage localised near surfaces ('surface effects') Under neutron bombardment, three forms of bulk damage are important—atom displacement, gas generation and the generation of solid transmutation products The degree of bulk damage is still significant in the region outside the breeding blanket, say at a neutron fluence of 10^{18} cm^{-2} Ductility, creep and stress-rupture/fatigue resistance, as well as the volume of metals, may all be modified and, in some metals, a sharp ductile-to-brittle transition occurs at a fluence of about 10^{20} cm^{-2} at room temperature Formation of gas bubbles may follow from gas generation and produce changes in mechanical properties by virtue of the accumulation of bubbles at grain boundaries[4] Void formation, a product of very extensive atom displacement[10] produces both swelling and a catastrophic loss of strength The fluence at which this effect sets in varies considerably with the type of metal, purity and temperature, varying from 5×10^{19} to 10^{22} cm^{-2} Even at 10^{18} cm^{-2}, before voids appear, the formation of other microstructures, such as interstitial loops and precipitates of supersaturated constituents, affects mechanical strength

Fig 1*a*, Segment of the United Kingdom Tokamak fusion reactor showing calculated neutron fluences for a life of 20 yr Structural design by Mitchell and George[6] External equipment shown may have to be placed outside the biological shield Outside diameter of segment is 4 m *b*, Cross section of the Reference Theta-Pinch Reactor (RTPR) showing functional regions of the toroid[5] Outside diameter of segment is 1 5 m

The resistivity of a metal is increased by the formation of defects, which act to scatter the current carriers At a fluence of 10^{17} cm^{-2} the resistivity of copper has increased by a few percent and, at 10^{19} cm^{-2}, by a factor of 4 (ref 11) In superconductors, the critical temperature for superconductivity and the current density are altered slightly by neutron fluences in the 10^{18} cm^{-2} range

Surface effects will be significant at those free surfaces of metals which are exposed to very high energy fluxes Neutron energy imparted to the lattice can cause sputtering and gas bubbles generated near surfaces can produce blisters which may then burst The first wall is the most heavily bombarded surface and the special surface effects expected here will be described later

The insulators in a CTR will have a less obvious but still demanding role Although, in general, metal parts will have been designed for a single role (for example, mechanical support or electrical conduction), insulators often have to fulfil combined mechanical and electrical roles and must therefore be more resistant to change To take a simple example, a high voltage feed-through insulator has both to support a conductor and to act as a barrier to conduction This electronic inactivity, however, is not easy to maintain when the material is being heavily excited by nuclear radiation at a high temperature The wide-band dielectrics are no longer insulators under these conditions (see, for example ref 12)

To emphasise the general and fundamental nature of these changes it should be pointed out that even at neutron fluence levels of the order of 10^{19} cm^{-2}, crystallinity is destroyed in many inorganic dielectrics at room temperature[13] and insulators, which are usually transparent in the visible and near ultraviolet, may, at this level of bombardment be opaque because of defect absorptions Likewise, organic materials, which rely on very specific molecular structures would, under these circumstances, receive sufficient energy to break every chemical bond several times Thus, unlike a metal, the insulator may undergo a partial breakdown of the main quantum mechanical features which determine its technological use—its low conductivity and wide band gap

Specific problems

Two well defined functional regions of the toroidal fusion reactor stand out as damage problems—the breeding blanket and the containment magnets In the first, the energy flux is very large and will include many species other than neutrons (α particles, γ rays, soft X rays, energetic ions, thermal plasma and so on), in the second, a critical level of performance has to be maintained Further, throughout the reactor, at points yet to be determined, there will be electrical and electromechanical components which must operate reliably, such as valves, relays and cables I shall deal with the main functional regions first

The first wall will be a thin metal barrier between the reactor vacuum and molten lithium coolant The most commonly quoted metal for the wall is a niobium alloy but other refractory metals (V, Mo) and several other groups of metals are being considered, for example austenitic stainless steels, nickel alloys, sintered aluminium powder, silicon carbide and graphite There have been no tests on these metals with 14 MeV neutrons at high temperatures and fluences because of the difficulty of generating intense neutron beams of this energy, but irradiations in high flux reactors (neutron energies in the range 0 1–5 MeV have been carried out on many stainless steels and the information has been supplemented by gas implantation experiments[10] Major stresses on the first wall will, however, be the repeated thermal shocks as the reaction is started and stopped cyclically, and the high stresses created by the

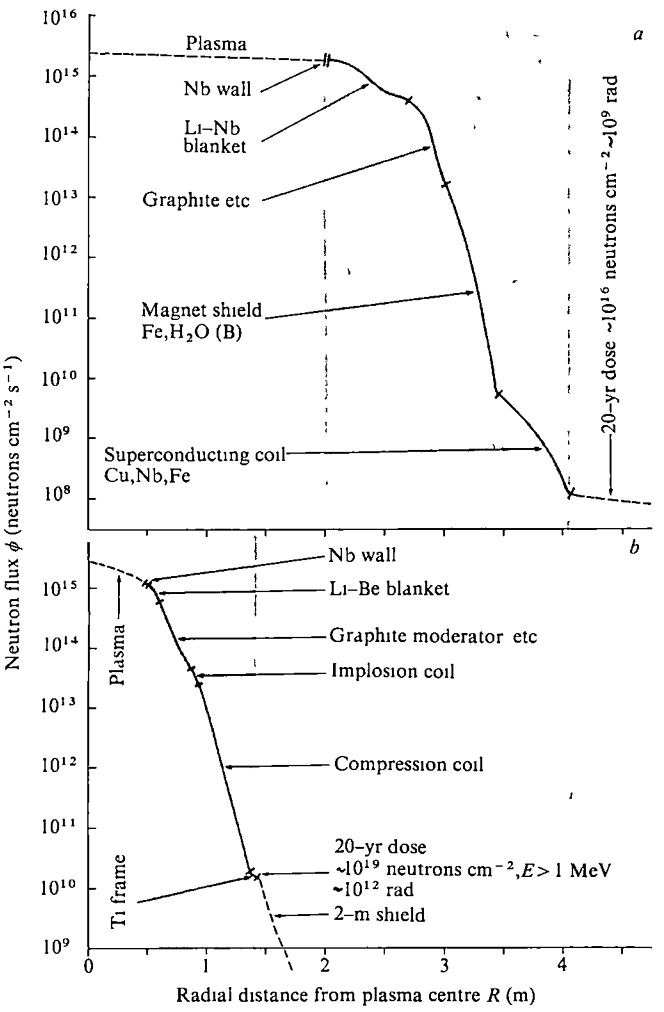

Fig 2 Radiation levels in (a) Tokamak[7] (10 MW cm^{-2}) and (b) RTPR[5] (6 7 MW cm^{-2}) showing larger size and heavier shielding in Tokamak Shading indicates functional structures

magnetic confinement field Such a cyclical mode of operation will vary in severity between the theta pinch and "DC" type of reactor but, in both cases, cyclical stresses will be much greater than have been experienced in fission power reactors, which are operated in a 'steady state' Unfortunately, theories of fatigue failure are not well advanced and thus it is fair to say that we do not yet know whether first wall can be fabricated which will take the stresses required at an economic size Mitchell and Booth, however, have evolved a flexible design of helium-cooled cell for the first wall which will allow the designer to minimise the mechanical forces acting on the wall[14]

The main surface effects which have to be considered for the first wall are

(a) thermal evaporation caused by the high energy flux,
(b) sputtering by the plasma ions, which will include deuterium, tritium, helium and some heavier ions originating in the wall,
(c) blistering arising from gas implantation,
(d) neutron sputtering

These effects are doubly deleterious to reactor operation since they result both in erosion and the introduction of impurities into the plasma The flux, φ, of ions from the plasma can be estimated using the expression

$$\varphi=[5\ 6\times10^{13}\ W/F]\ \mathrm{cm}^{-2}\ \mathrm{s}^{-1}$$

where W is the wall loading in MW m^{-2} and F is the fraction of ions which undergo fusion Sputtering yields are only known to within a factor of 2 to 3 for light ions[15] and the erosion rates of neutron sputtering and blistering effects are not yet established, since the phenomena have only recently been discovered Blistering effects vary with ion energy, target temperature and dose rate[16], apart from the spalling of the blistered surface, the blisters also act as thermal impedance and should lead to enhanced surface evaporation of the first wall Neutron sputtering was thought to be negligible[15] but Kaminsky and coworkers[17] have recently found rates to be higher than for light ions (as high as 0 25 atoms per neutron), which could lead to intolerable erosion rates

A major problem in the design of the theta-pinch type of reactor is that the first wall must be coated with an insulator to withstand the transient electrical field generated when the plasma is made to contract or implode[4] Operating at a temperature of over 600° C, it must withstand a field of about 10^7 V m^{-1} for about 1 μs When the plasma ignites, the insulator will be exposed to a thermal shock and a burst of particles Although Bunch and coworkers[9] feel that some forms of alumina ceramic may have the intrinsic mechanical strength to withstand the thermal effects, it is not yet known whether such a material will maintain its dielectric strength or integrity under the multiple particle and photon bombardment effects which will accumulate Table 2 lists some of these effects It is worth noting that the peak ionising dose rate in this insulator (A G H - S , unpublished) is likely to be greater than a rate which could lead to the transport of amperes of current per square metre of surface, and the material cannot be considered as insulating at all times

Superconducting magnets face both a radiation-heating problem and a radiation-damage problem The energy flux of neutrons at the magnet can cause excessive heating unless shielding is added within the confinement toroid The Tokamak design incorporates such a secondary shield of water-cooled steel McCracken and Blow[7] have made a detailed study of the neutron-induced changes in aluminium and copper, two of the materials which may be used as conducting matrices for superconductive filaments, these authors conclude that the neutron fluence over 20 yr can be allowed to rise to 10^{18} cm^{-2} if the magnets are allowed occasional annealing treatments, at room temperature or above Copper has advantages in strength over aluminium, and neutron irradiation actually improves the yield stress levels in copper, although more creep than usual occurs under neutron irradiation because of the enhanced atom motion Since the mechanical forces on conductors and the structure of powerful magnets are very high, creep effects may be significant Conductivity degradation is also one of the more difficult effects to simulate—mechanical forces have to be applied to metal and dielectric samples at high neutron fluxes and extremes of temperature At the moment test sources with the required neutron fluxes (about 10^{15} cm^{-2} s^{-1}) are not yet available and research may have to be started using fission neutrons and ion beams which can give the correct knock-on energies although only over limited volumes of material

In the theta-pinch design, the compression coils are not superconducting and no special measures are taken to reduce neutron heating Neutron fluxes will be more than four orders of magnitude higher but some of the damage will anneal as it is formed

The insulation of the magnet coil conductors presents more of a problem in both designs At present, thin organic layers are placed between each conductor, with organic potting to give the very necessary binding support The total radiation doses at the coil are probably high enough to destroy the mechanical properties of most organic insulators, and inorganic insulators will probably have to be used In the latter materials, displacement and transmutation can permanently increase conductivity and reduce breakdown strength, internal buildup of space charge can lead to very high internal fields and spontaneous breakdown

Table 2 Fusion reactor technology—summary of possible radiation effects problems in insulators

Physical phenomenon	Major functional effect	Class of components strongly affected	Basic studies (if any) needed	Possible technological solutions
(1) Electrical effects				
Generation of displacement defects leading to				
—Changes in carrier mobility* —Generation of defect levels	Changes in conductivity Changes in dielectric loss Changes in dielectric constant	First wall Standoff insulators Capacitors	Effects of defects on carrier transport Radiation induced defect production	Development of special neutron-tolerant glasses or ceramics with special doping grain size, and microstructure
Amorphisation leading to				
—Loss of directional properties	Piezoelectric device failure	Oscillators Acoustic devices	Physics of amorphous solids and amorphisation	Development of methods for depositing neutron-tolerant films of insulators
—Band-tailing and so on			Electrical breakdown	
Transmutation, precipitation of products	Changes in dielectric breakdown strength at precipitates and pores	All insulators	Precipitation of transmutation products	
Space-charge build-up	Internal breakdown Unwanted potentials		Charge traps in Insulators	
Photoconduction	Transient conductivity		Photoconductivity in insulators and interfaces	Insulators of optimised conductivity under irradiation (controlled leakage)
Changes in secondary emission and photoemission	Changes in first-wall emission efficiency		Surface barriers in solids	
(2) Optical effects				
Defect production	Changes in	First wall	Colour centres	Passivated, non-darkening surface coatings
	(a) transmission and reflectance	Windows	Emissivity	
Surface loss of stoichiometry	(b) absorptivity/emissivity relations controlling equilibrium with plasma	Light guides	Surface radiation damage	Radiation-tolerant light guides
			Surface reactivity	
(3) Thermal effects				
Colour-centre production	Decrease in radiative heat transfer	First wall	Colour centres	Dielectrics of high thermal conductivity
Lattice disruption and impurity precipitation	Decrease in heat transfer by way of lattice	Lagging of coolant pipes Superconductor insulation	Lattice vibrational modes	
(4) Mechanical effects				
Thermal shock Radiation-induced swelling (anisotropic) from defect formation	Fatigue fracture Microcracking Debonding Loss of strength	All dielectrics, especially first-wall coating, spacers and coil insulators	Microstructure and strength of materials Generation and rates of annealing of point defects and voids	Use of isotropically expanding dielectrics (e g glasses), Use of creep to relieve swelling Optimisation of powder size in ceramics Insulators with (a) Rapidly annealing defects (b) low void formation Special solid lubricants
Enhanced atom motion	Creep	Precision parts	Atomic diffusion under irradiation	
Phase changes and so on	Increase of friction Loss of directional properties and strength	Valves	Friction and microstructure	
		Piezoelectric devices	Radiation-induced phase changes	
Sputtering	Erosion of thin layers	First-wall coatings	Sputtering physics	
(5) Chemical effects				
Reduction by hot hydrogen	Reduction of oxides, nitrides etc	First wall Other coatings	Reactions of atomic hydrogen at surfaces	Passivated coatings
Diffusion of, for example, oxygen from insulators	Deoxygenation and so on of oxide insulators by Li, Nb and so on	First wall Oxide/Nb/Li system	Oxygen diffusion in metals and insulators	Oxygen diffusion barriers

* Carrier mobility has a strong influence on radiation induced conductivity in insulators

effects Finally, the leakage currents arising from photoconductive effects cannot be ignored In the case of the theta-pinch coil design, the coil insulators may experience dose rates in the region of 10^6 rad s^{-1} and photoconductivity may cause the resistivity of inorganic insulators to change from a normal 10^{18} to 10^{10} ohm cm during the pulse, leading to leakages in the ampere range Also, the use of implosion heating requires the application of a fast pulse at a voltage of more than 100 kV at the coil terminals, local fields could thus exceed the dielectric breakdown strength in the irradiated insulators In the case of superconducting coils, fields are low in normal circumstances but if the superconducting-to-normal transition occurs, a voltage of up to 20 kV can appear across the terminals Doses in the well shielded Tokamak magnets, however, will probably be only $\sim 10^2$ rad s^{-1}

Proceeding from the plasma outwards, the first region in which electronic devices might be placed would be in the void between the coils and the biological shield Some control circuits and actuators for the coolant and vacuum pumping systems may need to be near the torus Radiation dose rates can be reduced by local shielding but a 20-yr zero-shield figure of 10^{16} neutrons cm^{-2} and 10^8 rad for this void region is not unreasonable to expect This is a level which requires a special selection of all semiconductor and dielectric parts (including organics) used in this region[8]

There remains a class of damage problems which cannot yet be described in detail but of which the outlines are clear The nuclear fuels, deuterium and tritium, must be passed into the reactor, probably by means of particle (pellet or ion) accelerators, currents must be passed through the plasma, impurities must be "diverted"[18], spent fuel must be pumped out, eddy currents must be suppressed Each of these functions requires the presence of a virtually independent subsystem—as yet of uncertain design—with elements near to the plasma The materials needed and the fluxes to which they will be exposed will become known as the detailed geometry of reactors is developed (see, for example ref 19) but it is not too early to develop a general knowledge of the effects of high fluxes of neutron on those types of metal which may be used and of combined neutron–γ effects on the dielectrics Some idea of the materials of interest can be gained by examining the materials commonly used in various component technologies (see, for example refs 8 and 20) A case in point is the window problem in the laser fusion reactor (see for example, paper 8 of ref 4) Light transmission, reflectivity and dimensional stability are all key performance parameters in this precision optical system and, as Table 2 shows, all are affected strongly by high levels of neutron and γ irradiation (estimated doses are $2\times10^{20}\ \mathrm{cm^{-2}\ yr^{-1}}$ and $10^{11}\ \mathrm{rad\ yr^{-1}}$, respectively)

Basic research needed

This list of hazards for the CTR system need not make us drop the idea of building such a machine The research on radiation effects done in support of the fission reactor programme and the 'hardening' of semiconductor devices for aerospace use has shown that solutions can usually be found for each problem if an understanding of the phenomenon is first achieved, however, such solutions have often in the past proved to be highly individual and specific (see, for example, the beneficial use of lithium in silicon solar cells[21] which, however, does not benefit silicon transistors) and take a long time to put into effect Thus, if fusion technology is to proceed according to a proper timetable, a form of 'preventive research' must be undertaken in which the basic phenomena of radiation effects for any material of interest are studied to the point that any potentially crippling problems of degradation will have been noticed before the development of that material has proceeded unduly far[20]

For metals, some of the damage phenomena described in the earlier sections are already being studied as part of fast fission reactor development, but these must be widened to include surface effects and to embrace a wider range of metals For dielectrics, Table 2 provides a comprehensive list of damage phenomena In looking for neutron-tolerant dielectrics, the glasses are of special interest because they are not prone to the anisotropic expansion which can lead to loss of strength in crystalline insulators[22] The fission reactor programme has already demonstrated the tolerance of certain refractory oxides and other ceramics to radiation It is assumed that semiconductors will be virtually excluded from the high flux regions[8]

In the field of theory, recommendations have been made for development in theoretical models for creep, embrittlement, crack formation and void formation, especially in the refractory metals[23], for dielectrics, models will be required for damage to electrical and optical properties as well as to mechanical properties Up to now, the electrical and optical properties of insulators have not been of central importance in the nuclear energy field and as a result, there is a smaller body of damage theory on which to base future work than for metals Furthermore, the technologically important oxides (such as silica, alumina and zirconia) are crystallographically complex and for this reason have not received the required degree of attention from theoreticians as media for band theory and defect studies

Aims and timetable

Having stated the topics for basic research, I shall briefly lay out a set of technological aims for dealing with radiation effects in CTR components, based on a timetable for general CTR development by Hancox[24], as follows

Metals. (1) Development of structural metals with minimum change in ductility, creep, stress rupture, fatigue and swelling under high neutron fluences at high temperatures (and with high resistance to corrosion by the breeding material) (2) Development of conductor/superconductor with the minimum change in resistivity and creep strength at very low temperatures and moderate neutron fluences (3) Control of surface erosion phenomena such as blistering, sputtering and gas desorption

Insulators. (1) Development of structural ceramics and glasses and a range of electronically passive thin coatings resistant to radiation-induced swelling, cracking, leakage, high voltage breakdown and chemical attack (2) Development of special deposition methods for insulating coatings (3) Development of radiation tolerant light-handling media (4) Development of dielectric materials to perform special electronic functions under high neutron-γ ionisation

Taking 1979–84 as the period during which feasibility of fusion reactors will be tested, we can also draw up a tentative timetable giving a concerted fundamental and technological development and which will permit the successful construction of short lived experimental reactors by 1979 and long lived, economic prototype reactors in the early 1980s, as follows

1974–79: Preparatory research. Fundamental research on damage and structure of reactor materials, especially dimensional stability of metals and electronic stability of dielectrics, initial development of specific radiation-tolerant structures (especially electro-mechanical or electro-optical devices) required for the demonstration power reactor to be designed in the 1980–82 period, Simulation of neutron-γ, ultraviolet and plasma effects in metals and insulators using electron, ion and proton bombardment and the highest fluxes of non-fusion neutrons available, experiments on lower levels of neutron fluxes from early fusion plasma experiments (as available) for comparison with non-fusion sources

1979–82· Feasibility testing Fabrication of prototype radiation-tolerant materials and devices for a demonstration reactor, exposure of samples in feasibility-test reactor, full design of test rigs for demonstration reactor

1982–90: Demonstration reactor. Fabrication of radiation-tolerant materials and devices for demonstration reactor, accelerated life tests for 20-yr operation of prototype reactor, development of second generation of radiation tolerant materials and devices for a possible prototype commercial CTR

Conclusions

This review of one branch of fusion reactor technology has been made with the idea of distinguishing problems in radiation effects which deserve to be investigated during the next few years, even before reactor designs are finalised The field of insulator study has perhaps been given greater emphasis than that of metals because the latter has been dealt with at length in recent conferences and workshops while the latter has been somewhat neglected by comparison, thus, the multiplicity of effects produced in materials with a wide band gap has been stressed It seems, however that the strength of metals under irradiation may be the limiting factor in the life and efficiency of controlled thermonuclear reactors and thus an extensive programme of research and testing of metals should continue for the rest of this decade For both insulators and metals, techniques of predicting and dealing with radiation effects will need to be improved and 'preventive research' carried out on many of the less obvious materials The intelligent direction of resarch may well help to achieve the target of useful fusion power in the national grid not long after the beginning of the next century

I acknowledge the liberal assistance of Dr G McCracken in supplying details and comment on the United Kingdom Tokamak, making constructive comments on the manuscript and allowing the use of some unpublished text material F W Clinard, jun, of Los Alamos Scientific Laboratory made some useful comments on Table 2 in proof in a recent discussion

Note added in proof For Tokamak reactors it may be required that the torus as a whole must not constitute a closed conducting loop A completely insulating segment must thus be inserted in the torus, the inner edge of which will be exposed to the plasma This segment or "spacer" will have to maintain strength, dimensional stability and electrical properties over the range of radiation doses shown in Fig 2*a*

Evidence for the breakup of eastern Gondwanaland by the early Cretaceous

Rudi G. Markl

Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York 10964

An analysis of early Cretaceous marine magnetic anomalies of south-western Australia helps to piece together eastern Gondwanaland It is suggested that India once abutted Western Australia

THE seafloor spreading history of the portion of the Indian Ocean basin between the Ninetyeast Ridge and Australia, the Wharton Basin, is poorly understood Most Gondwanaland reconstructions have placed the eastern coast of peninsular India against Antarctica, generally leaving a gap of about 15° of longitude between India and Australia[1-5] Some workers have placed the eastern coast of India against Western Australia[6-8] and yet others have favoured placing Indonesia, south-east Asia, even China, against Western Australia[9-11] I present here new evidence pertaining to the reconstruction of eastern Gondwanaland, the recognition of early Cretaceous marine magnetic anomalies adjacent to south-western Australia

Anomalies M-1 to M-11 inclusive of Larson and Pitman[12] have been identified between the northern edge of the Naturaliste Plateau and the Australian mainland The lineations, referred to here as the 'Perth sequence', vary in strike from 040° near the plateau to 020° near the mainland, they demonstrate that the age of the oceanic crust increases toward the continent (Fig 1) Although somewhat older crust may exist beneath the continental margin, the presence of anomaly M-11 dates the separation of India (?) and Australia in this region at 127 Myr BP, or earlier This date is nearly coincident with that determined for the opening of the South Atlantic Ocean[13]

Larson *et al*[14], suggested that the time scale of Larson and Pitman[12] should be compressed by 10–15% relative to anomaly M-22 A 10% compression has been used here

Anomalies M-2 and M-4, the most distinctive of the younger half of the M series, correlate well from track to track (Fig 2) The correlation of anomaly M-2 is dashed south of profile EL48 because tracks 1106-2 and EL54 cross onto the Naturaliste Plateau in this vicinity The model anomaly profile (Fig 2) uses a magnetic layer 500 m thick, with a remanent magnetisation intensity of 0 012 e m u cm^{-3} Models were also calculated for remanent magnetisation acquired at palaeolatitudes 50–70° S and for subsequent rotations of the plate of as much as 40°, both clockwise and anticlockwise The correspondence to the observed data, however, was not greatly affected The model profile used here (Fig 2) is for latitude 60° S and no subsequent rotation The correspondence between the observed anomalies and this model is comparable to that of the equivalent portions of the Cape basin sequence[13] and the Keathley sequence[15], which also exhibit relatively slow spreading rates

The identification of the M series is substantiated by Site 259 of the Deep Sea Drilling Project (DSDP), which gave

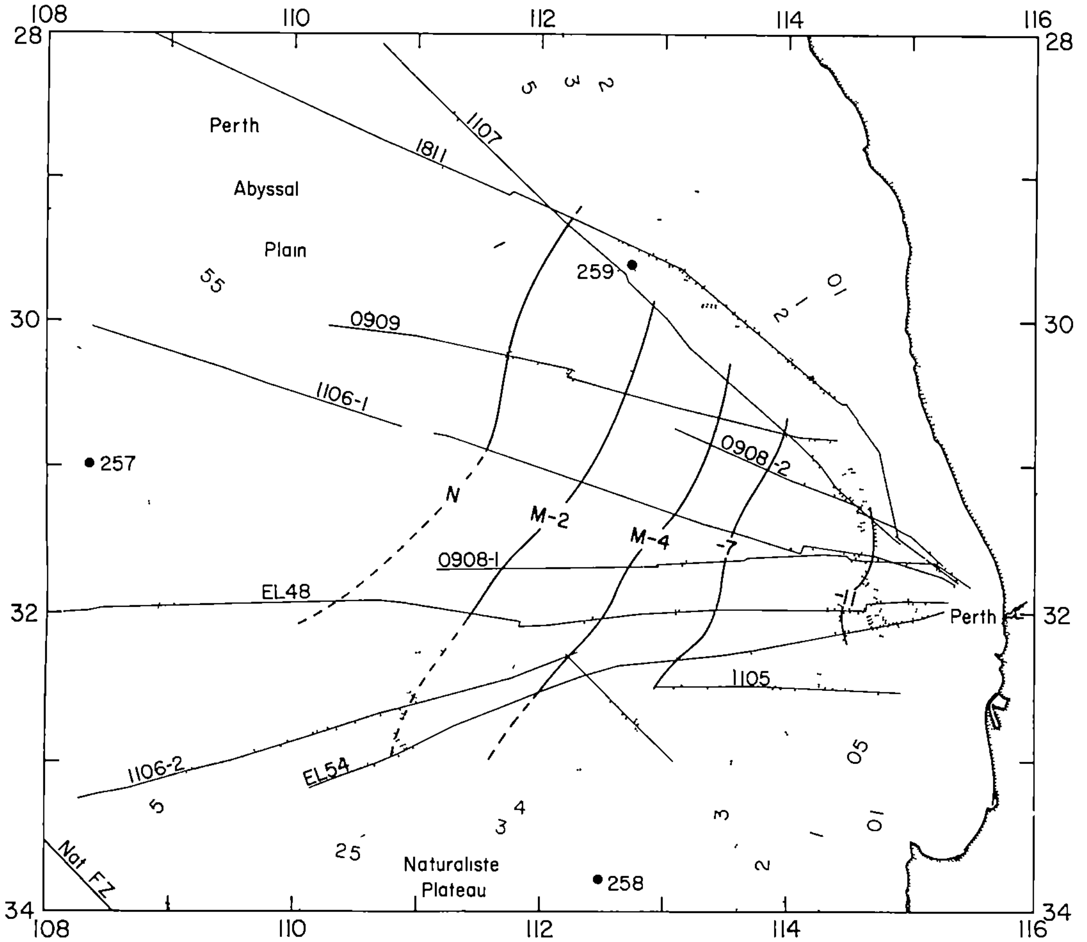

Fig 1 The Perth sequence of Mesozoic (M) magnetic lineations showing the portions of the ship tracks corresponding to the observed profiles shown in Fig 2 ●, DSDP site numbers, N, negative magnetic anomaly The bathymetric contours are in corrected metres

a basal sediment age of greater than 110 Myr (ref 16) Calculations based on anomalies M-2 (116 Myr BP) and M-11 (127 Myr BP) indicate that the (half) spreading rate during this period was 2 3 cm yr^{-1} Site 257, located in the late Cretaceous 'quiet zone'[17], yielded an age from near basal sediments of 102 Myr (ref 18), which corresponds to a (half) spreading rate of 2 1 cm yr^{-1} between Site 257 and the M-2 lineation

A negative anomaly just west of (younger than) the Perth sequence has also been correlated (Figs 1 and 2) This anomaly is probably equivalent to a negative anomaly adjacent to the Cape basin sequence which may represent a magnetic reversal[13]

Sclater and Fisher[11] identified east–west trending lineations (Fig 3) which indicate that the age of the crust of the northern Wharton Basin increases towards the south The assumption that this spreading regime also created the crust of the southern Wharton Basin led them to conclude that India could not have abutted Australia in Gondwanaland

The Perth sequence, although oriented at about 55° to the younger lineations of Sclater and Fisher[11], was initially considered to be related probably to some segment of their anomaly pattern, perhaps to the sliver bounded by their proposed 96° E and Investigator fracture zones (Fig 3) The intervening 20° of latitude between anomaly 33b (ref 11) and anomaly M-1 would represent the late Cretaceous (115–85 Myr BP) magnetic quiet period This scheme for the origin of the Perth sequence would require an average (half) spreading rate of more than 7 cm yr^{-1} during the quiet period, and a shift of the pole of rotation commensurate with the required change from NW–SE to N–S spreading The (half) spreading rate between DSDP Site 212 (approximately 95 Myr BP) (ref 19), which is 330 km south of anomaly 33b (Fig 3), and Site 256 (basal sediment age 101 Myr) (ref 18), is about 8 cm yr^{-1} However, the fact that Site 257 is fully 1,100 km south-east of Site 256, has the same age as Site 256, is obviously inconsistent with this scheme The slow spreading rate of the Perth sequence (2 3 cm yr^{-1}) also implies that the achievement of a 7 cm yr^{-1} average spreading rate between anomalies M-1 and 33b is not realistic Additional magnetic evidence from the southern Wharton Basin offers an alternative mode of origin for the Perth sequence

The overall 'unquietness' of the supposed quiet zone in the southern Wharton Basin is disturbing Peak-to-peak amplitudes of up to 700 γ are common These anomalies seem to be unrelated to the basement morphology and in many instances they can be correlated from track to track The similar basement ages of DSDP Sites 256 and 257, combined with a varying degree of axial symmetry on magnetic profiles in the quiet zone between these sites, led to the recognition of anomalies believed to be M-1 to M-22 inclusive, between the northern extension of Broken Ridge (Fig 3) and Ninetyeast Ridge Anomalies M-2 and M-4 can be traced for more than 400 km, striking 040° (Fig 3) The identification of the older anomalies is, however, based upon only one track—Vema 18—(Fig 4) In Fig 4 this profile is shown with a model anomaly profile for remanent magnetisation acquired at 60°S and 0° declination The character of anomalies M-1 to M-11 inclusive and their correlation with the model, is similar to that of the anomalies of the Perth sequence, the correlation of the observed and model profiles between anomalies M-11 and M-22 is poor The spreading rate between anomalies M-2 and M-22 is 1 6 cm yr^{-1} A negative anomaly just east of anomaly M-2 has been correlated between tracks, but it is questionable whether this anomaly is equivalent to the negative anomaly west of the Perth sequence Site 255 lies 70 km south-east of the extrapolated trend of anomaly M-2 It is, however, located on top of Broken Ridge, and it terminates 200 m above the basement, in 80-Myr-old material[18] Therefore it

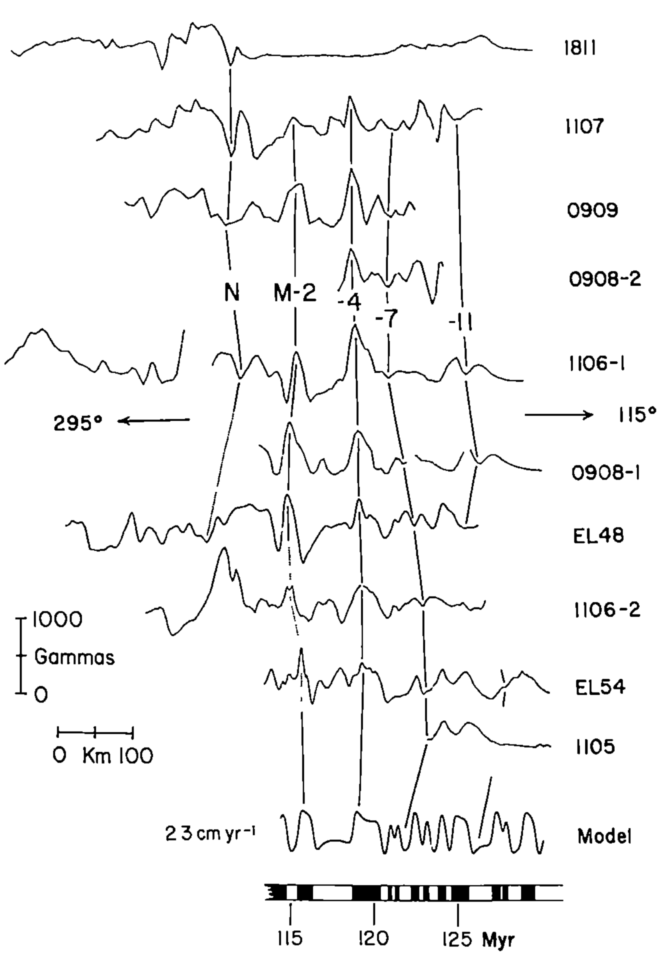

Fig 2 Observed magnetic profiles of the Perth sequence projected perpendicular to the strike of the lineations and plotted above the model anomaly profile, the latter was computed from the magnetic block model of Larson and Pitman[12]

probably has no potential as a support for the identification of the Broken Ridge sequence Lamont-Doherty has no data north of the Vema 18 track but profiles Lusiad-3 Project Magnet 541 (refs 11, 20) show anomalies which may represent M-2 and M-4 Along the LU-3 track the possible M-2 anomaly lies 155 km north-west of Site 256 (101 Myr BP), which would correspond to a (half) spreading rate of only 1 0 cm yr^{-1} The LU-3 data suggest that the lineations may curve toward the north (Fig 3) If the Project Magnet 541 data are also used, a 75 km sinistral offset of the lineations just north of the Vema 18 track is implied An offset here is not altogether unlikely, in view of the trend of a previously unreported fracture referred to here as the 'Naturaliste fracture zone' (Fig 3) The strike of this 650 km long fracture zone is well defined by seismic and bathymetric data in the vicinity of the Naturaliste Plateau

The axis of the spreading centre inferred to have generated the Perth and Broken Ridge sequences is not well delineated Figure 5 shows observed magnetic profiles from the quiet zone between the Perth and Broken Ridge sequences The corresponding track lines, as well as the trends of correlated anomalies, are shown in Fig 3 The magnetic trends consistently strike NE–SW to NNE–SSW, providing another argument against the probability of a direct relationship between the Sclater and Fisher pattern and the Perth sequence A prominent negative anomaly defines the axis of symmetry on profiles EL45 and 1105 (Fig 5) With the exception of the central anomaly, the large positive anomalies between C and C′ on profile 0909 are associated with large seamounts North of profile 0909 the position of the axis is based upon the overall symmetry of the magnetic profiles Bathymetric and seismic reflection data show that the northern half of the inferred axis of spreading coincides with the axis of a regional topographic and basement high The basement topography across the axis is generally smooth compared with active ridge crests although discrete seamounts are abundant in the axial zone between latitudes 28° and 29° S The positions of basement scarps which flank the axis are shown in Fig 3 The average thickness of sediment in the axial zone varies from 700 m at the southern end to 300 m in the north

Extrapolation of the spreading rates of the Perth and Broken Ridge sequences indicates that the inferred spreading centre would have become inactive by about 77 Myr BP The average basement depth in the axial zone is 5,275 m This depth compares favourably with the depth predicted (approximately 5,400 m) for a slow spreading ridge 77 Myr after the cessation of spreading[21]

There is a reasonable case for the existence of an extinct spreading axis in this region An approximate symmetry exists in the magnetic profiles along several tracks The axis of symmetry is essentially perpendicular to the trend of the Naturaliste fracture zone and parallel to those of the Perth and Broken Ridge sequence lineations The distance from the axis to these sequences is roughly proportional to their respective spreading rates, and it lies essentially midway between two holes of the same age (Sites 256 and 257)

Although the proposed late Jurassic–late Cretaceous spreading centre provides an explanation for the problem of the widely-spaced but similarly aged DSDP sites in the southern Wharton Basin[18 22], it bears problems of its own Anomaly M-11 lies adjacent to Australia and is the oldest anomaly of the Perth sequence The oldest identifiable anomaly of the poorly documented Broken Ridge sequence is, however, M-22, and there is room between M-22 and the Ninetyeast Ridge for still older crust This apparent discrepancy in the time of inception of spreading (as well as the apparent asymmetry of the spreading rates of the two sequences) may be alleviated by the fact that when the M-2 lineation (from Vema 18 southward) of the Broken Ridge sequence is rotated into alignment with the M-2 lineation of the Perth sequence, the former sequence is not juxtaposed with the latter Instead, the Broken Ridge sequence lies to the south-west, on the opposite side of the Naturaliste fracture zone This rotation of 13 4° about a pole at 40°N, 175°E leaves the Naturaliste fracture zone perpendicular to the lineations

Another difficulty which must be explained is the presence of the northern extension of Broken Ridge, which roughly parallels the magnetic lineations (Fig 3) Seismic profiles show that the northern end of this feature (delineated by the 3,000 m isobath) resembles the Naturaliste Plateau Although it is possible to fit these two plateaux together, the presence of the northern extension on crust which post-dates the inception of spreading (anomaly M-11) by 15–20 Myr precludes a simple rifted origin

As already stated, the spreading centre in the southern Wharton Basin might have become inactive by 77 Myr BP Anomaly 33 is not discernible in the axial zone, and as the magnetically quiet period is believed to have been marked by a pulse of rapid spreading[12], the cessation of spreading probably occurred earlier The presence of anomaly 33b in the northern Wharton Basin[11] indicates that the spreading centre which generated it was active by about 80 Myr BP No structural feature is known in the area between the two regimes (lat 20°–22°S) which could suggest the location of a possible boundary between them The magnetic anomalies in this area are typical of a quiet zone One way to reconcile these two spreading regimes is to postulate that the older spreading axis jumped to an east–west

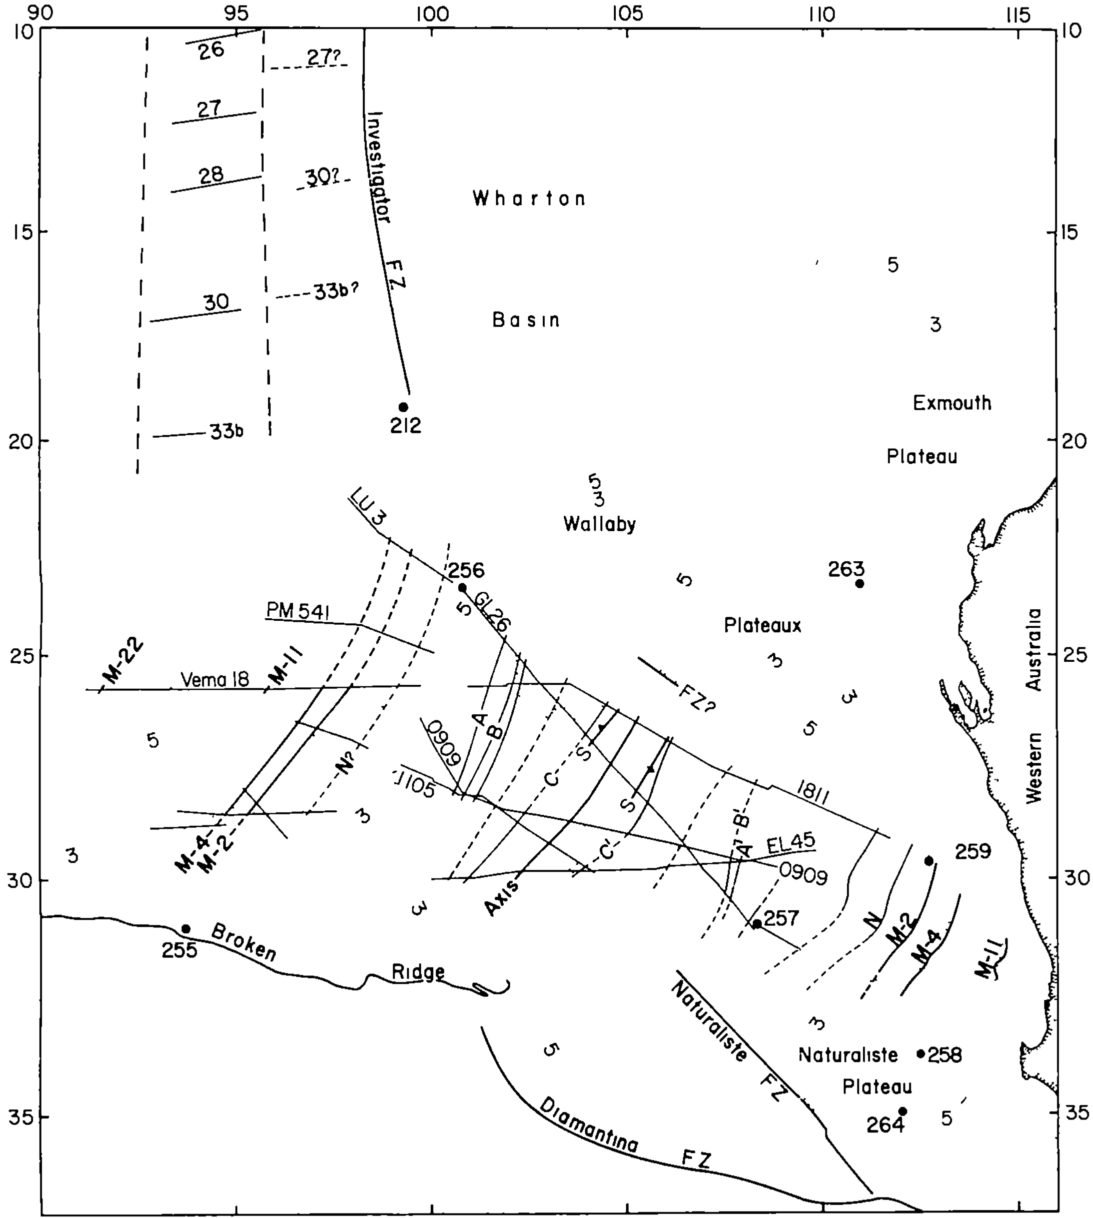

Fig 3 Map of the Wharton basin showing the southern half of the anomaly pattern of Sclater and Fisher[11] (anomalies 26–33b), the Perth and Broken Ridge sequences of Mesozoic (M) magnetic anomalies, and the axis of the proposed spreading centre Magnetic lineations A, A', and so on, are derived from observed profiles shown in Fig 5 Wall Plat, Wallaby Plateau, N, correlated negative magnetic anomaly, dotted lines labelled '3' and '5', the 3,000 and 5,000 corrected meter isobaths respectively, S, basement scarps, unlabelled lines crossing the Broken Ridge lineations, segments of L-DGO tracks on which anomalies M-2 and M-4 were observed, FZ, fracture zones, ●, DSDP site numbers

orientation just before the end of the quiet period, and swept pre-existing 'Tethyan' and Mesozoic crust, and finally its own northern flank, northwards into the Java trench (aided since about 55 Myr BP by the northward spreading of the present South-east Indian Ridge)

The orthogonal relationship between the Perth magnetic lineations and the Naturaliste fracture zone suggests that the Australian continental margin from Perth to the Wallaby plateaux was an initial line of weakness along which transform faulting occurred This geometry also suggests that the northern margin of the Naturaliste Plateau (Fig 1) owes its shape to initial rifting and transform faulting If the identification of the Broken Ridge sequence as Mesozoic-age anomalies is correct, then the oldest crust in the southern Wharton basin (early to middle Jurassic) should lie between latitudes 18°–23°S just east of the Ninetyeast Ridge

Whatever its mode of origin, the existence of the Perth sequence has important ramifications regarding the breakup of eastern Gondwanaland and the evolution of the eastern Indian Ocean The Perth lineations are consistent with the DSDP data and stratigraphical evidence from the coastal basins of Western Australia[7] in that they disallow a gap in Gondwanaland west of Australia, at least in late Jurassic times The seafloor of the region of the inferred gap, that is, the present southern Wharton Basin, is not of Tethyan vintage, but has been created since the breakup of Gondwanaland The Perth sequence by itself provides no indication as to which continental block lay adjacent to Western Australia, but it does prove that the block began to drift away to the north-west before the formation of anomaly M-11 (127 Myr BP) The trend of the Broken Ridge and quiet zone lineations indicates that the continental block

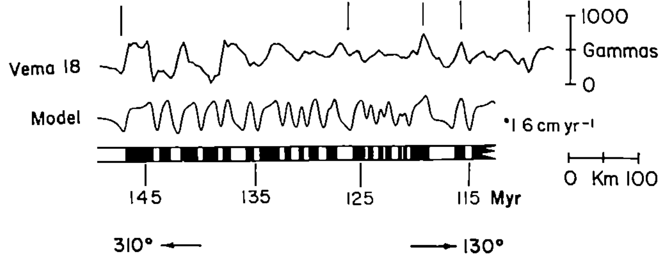

Fig 4 Observed magnetic profile Vema 18 projected perpendicular to the strike of anomaly M-2 and plotted above the model anomaly profile and block model, the corresponding track segment is shown in Fig 3

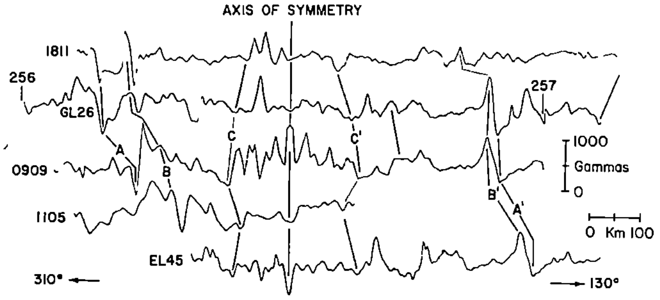

Fig. 5 Observed magnetic anomaly profiles across the proposed spreading centre in the quiet zone between the Perth and Broken Ridge sequences The profiles are projected perpendicular to the axis of symmetry, the corresponding track segments are shown in Fig 3 Anomalies A–A′ to C–C′ correlate, and may be isochronous

in question continued to move in a north-westerly direction The late Jurassic–late Cretaceous spreading centre postulated here indicates that the block could have reached the vicinity of longitude 90°E by the time north–south spreading began adjacent to the present Ninetyeast Ridge[11,20] This scenario strongly suggests that India was the continental block that abutted Western Australia

I thank Drs Roger Larson and Dennis Hayes for discussions This research has been sponsored by the Office of Polar Programs of the National Science Foundation

Gene duplication in experimental enzyme evolution

Peter W. J. Rigby*, Bruce D. Burleigh, jun.† & Brian S. Hartley‡

Medical Research Council, Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, England

A system to study enzyme evolution experimentally has been developed Multiple mutations are required to improve enzyme specificity and the authors propose that such mutations will be acceptable only in 'silent' gene copies—shown here to be a frequent response to selective pressure

DIVERGENT evolution of an enzyme family from a common ancestor must involve gene duplication as the first step, followed by mutation of one copy to a 'silent gene' that produces an inactive product that cannot fold correctly[1] Natural selection will conserve the sequence of the viable copy but the progeny of the silent gene will become heterogeneous in the population by both mutation and recombination A reversion of the original lesion or a compensating mutation may restore at any time the capacity of the protein to fold correctly and mutations accumulated in the 'silent' phase will then be expressed Natural selection may refine the structure thereafter either back to the old specificity—whereby isoenzymes would result —or to a new specificity, establishing an enzyme family

Some evidence for this hypothesis can be gleaned from the tertiary structures of the serine proteinases, trypsin, chymotrypsin and elastase[2] The conformations of their polypeptide chains are almost superimposable and most of the internal residues are identical or chemically similar Only one or two changes in the surface are adequate to explain their different specificities, but over 80% of the rest of the surface residues are different Even in the highly conserved interiors there are clusters of different residues that seem to provide radically different solutions to the same space-filling problem It is hard to see how these alternative arrangements could have evolved without going through an intermediate that could not fold correctly

The fossil evidence that would support these evolutionary hypotheses has long since been degraded, however, and we are aware of the weakness of arguments based only on comparisons of contemporary structures—even of tertiary structures Some discipline would be imposed on our imagination if we could observe in detail the evolution of an enzyme towards a new specificity under precisely defined selective pressure

Continuous culture of microorganisms in a chemostat represents a closed ecological niche in which the biological fitness of the organism can be measured by the steady-state biomass and concentration of growth-limiting nutri-

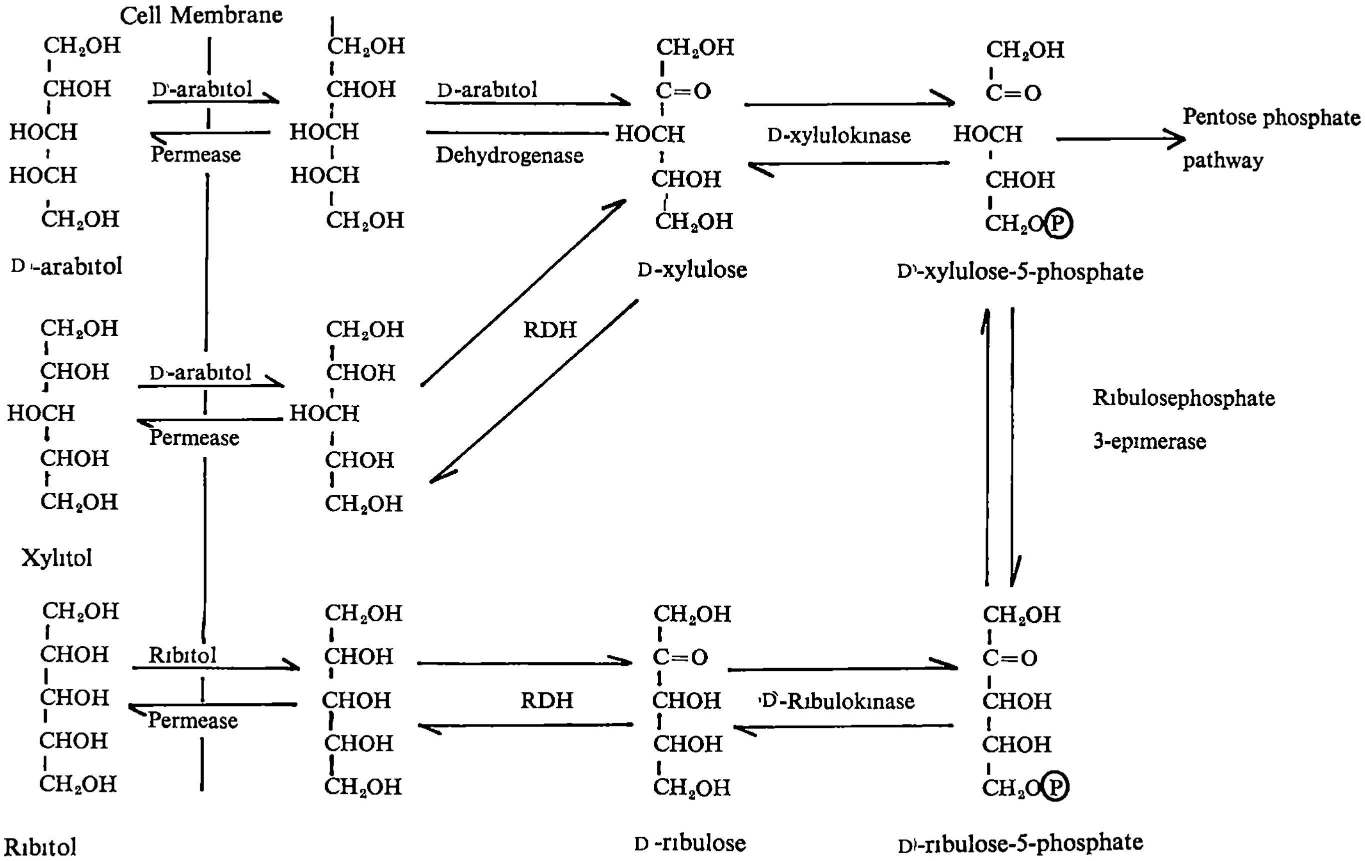

Fig 1 Pentitol metabolism in *Klebsiella aerogenes*

ment in the effluent If the growth-limiting carbon source is a poor substrate for an essential catabolic enzyme, growth may be limited by the activity of this enzyme Mutants with increased enzyme activity will outgrow the ancestral strain and displace them from the niche[3] Such an 'evolutionary step' will be signalled by a rise in steady-state biomass and a fall in effluent substrate level Samples of the 'ancestral' and 'evolvant' cultures can be stored as 'fossils' and batch cultures of these can be grown separately to examine the properties of the enzyme in each strain

Evolution of ribitol dehydrogenase

The pioneering studies of Mortlock and Wood[4] and of Lin[5] and their colleagues on the growth of *Klebsiella aerogenes* on pentitols, established the metabolic pathways shown in Fig 1 The wild type organism will grow on ribitol or D-arabitol as sole carbon source, having an inducible pentitol permease, ribitol dehydrogenase (RDH) (ribitol NAD oxidoreductase E C 1 1 1 c) and D-arabitol dehydrogenase Xylitol and L-arabitol, which are not normally found in nature, will not support growth of the wild type organism, but mutants that are constitutive for ribitol dehydrogenase will grow slowly on these 'unnatural' pentitols Their metabolism has been conclusively demonstrated[6] to be by a side specificity of ribitol dehydrogenase, but whereas the apparent K_m for ribitol was about 1 mM, that for xylitol and L-arabitol was around 1 M It was likely, therefore, that the activity of this enzyme would limit the growth of *K aerogenes* on xylitol in continuous culture, since the pentitol permease seems to transport xylitol efficiently

We therefore began an extensive study of the activity of ribitol dehydrogenase in continuous cultures of a constitutive strain, A, of *K aerogenes* (strain X1 (ref 5)) This was grown in a minimal salts medium with xylitol (0 2% w/v) as sole carbon source in a continuous culture apparatus of our own design and manufacture based on the Porton type fermenter[7] The appearance of better adapted strains was followed by monitoring the bacterial dry weight and residual substrate level in the chemostat

To demonstrate that our system would select putative evolvants we grew an arginine-requiring derivative of strain A on medium supplemented with arginine and guanine, at steady state the chemostat contained approximately 10^{12} cells We then inoculated with 20 cells of a guanine-requiring derivative of strain B (strain X2 (ref 5)) which has a mutant ribitol dehydrogenase with an apparent K_m for xylitol of 0 5 M Twenty cells were used to avoid the statistical chance that the fitter strain would be eliminated[3] Takeover was monitored by measuring normal chemostat parameters (Fig 2*a*) and by plating on appropriate media (Fig 2*b*), these data show that takeover was complete within 7 d

Spontaneous evolution

Our initial experiments (summarised in Fig 3 and Table 1) were performed without mutagenesis to mimic natural evolution Strains A1 and A11 were investigated in detail (Table 1) The apparent maximum specific growth rates on 0 2% xylitol, measured by the washout technique of Tempest[8], confirmed that both strains had increased fitness for their environment The ribitol dehydrogenase activity of strains A, A1 and A11 was measured in cell free extracts obtained by ultrasonication of saturated batch cultures grown on xylitol Neither the apparent K_m for xylitol nor the ratio of xylitol activity to ribitol activity was altered, but a significant increase in total enzyme activity occurred at each step

Is this due to superproduction of wild type enzyme or to evolution of enzymes with increased catalytic efficiency? We purified each of these enzymes to homogeneity by the methods of Taylor, Rigby and Hartley[9], and examined their kinetic parameters There was no detectable change in enzyme activity (Table 1), but it is clear from the purification schedules (Table 2) that strain A1 makes five times

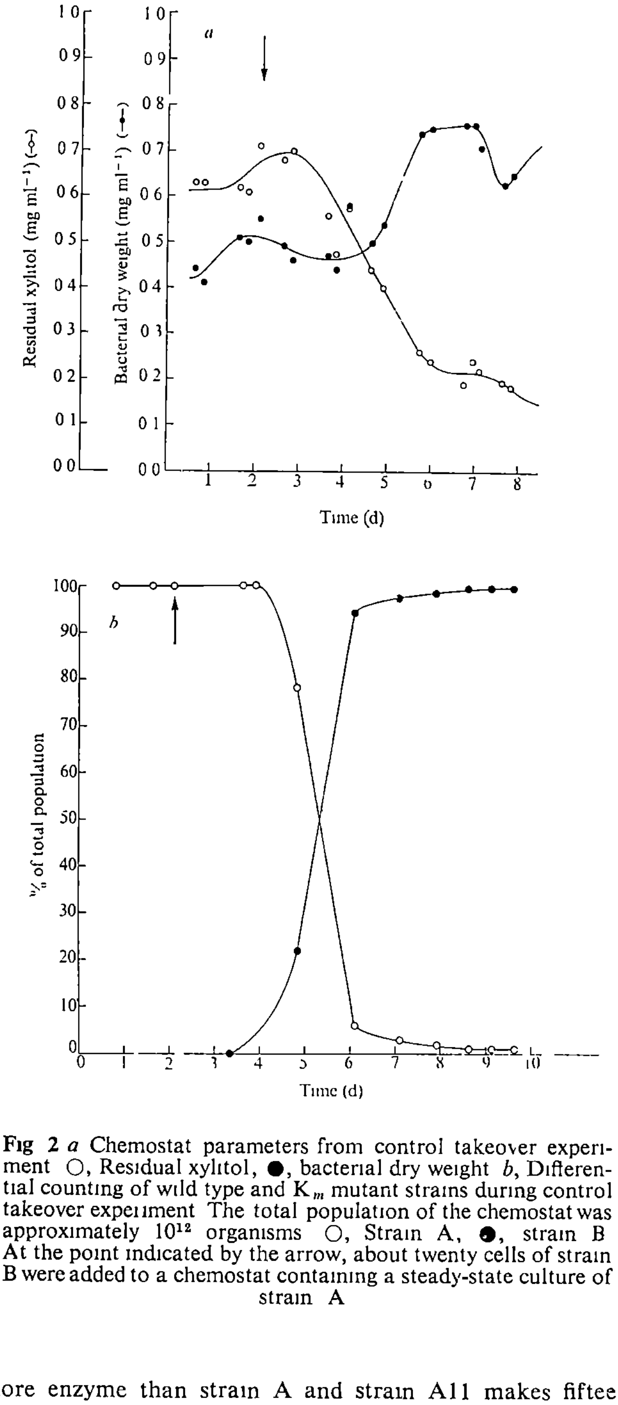

Fig 2 *a* Chemostat parameters from control takeover experiment O, Residual xylitol, ●, bacterial dry weight *b*, Differential counting of wild type and K_m mutant strains during control takeover experiment The total population of the chemostat was approximately 10^{12} organisms O, Strain A, ●, strain B At the point indicated by the arrow, about twenty cells of strain B were added to a chemostat containing a steady-state culture of strain A

more enzyme than strain A and strain A11 makes fifteen times more In the latter case the enzyme represents 17% of the total protein in the extract

Spontaneous evolution gives only increased enzyme production Will specific mutagenesis change this pattern? We built a small ultraviolet lamp into our chemostat and irradiated cultures at a low level such that about 10% of such treatments failed to initiate takeover events The genealogy of fitter strains selected in this way is shown in Fig 3, and Table 1 lists the properties of a typical pair Strain A2 appeared by all criteria to be wild type, but strains A21 and A211 contained elevated levels of enzyme The enzyme was purified to homogeneity from these strains and was kinetically indistinguishable from wild type (Table 1) Similar results were found for all the ultraviolet-induced evolvants shown in Fig 3, 20% of the total protein of strain A6111 was ribitol dehydrogenase Superproduction of wild-type enzyme seems to be the invariable response of the organism to this selective pressure, whether mutations arise spontaneously or are induced by low levels of mutagenesis ●

Enzyme superproduction

Our original hypothesis about evolution of new enzymes demands gene-doubling as the first step Is gene-doubling the explanation for enzyme superproduction, or are other phenomena responsible, such as promoter mutations which lead to high transcription rates for the gene? To distinguish gene-doubled strains we measured the frequency at which mutants lacking ribitol dehydrogenase occurred in strains A, A1 and A11 If the probability of a bacterium carrying a single RDH gene mutating to be RDH^- is P, then that for a bacterium carrying two copies is P^2, for one carrying three copies P^3 and so on This makes the reasonable assumption that each copy will be equally mutable at sites essential for enzyme function

Parallel cultures of each strain were subjected to mutagenesis with N-methyl-N′-nitro-N-nitrosoguanidine followed by a penicillin selection against xylitol Mutants unable to grow on xylitol but able to grow on D-xylose were isolated by replica plating, those which retained the ability to grow on ribitol, being revertants of the constitutive mutation, were discarded This screening procedure produces a set of mutants which contains both RDH and permease negatives, these were distinguished by testing each xylitol-negative clone for ribitol dehydrogenase activity The mutation frequency for the wild type is sufficient to guarantee against the isolation of dependent mutants

Table 3 shows that strains A and A1 have approximately equal mutation frequencies whereas that for strain A11 must be less than the square of the wild type frequency This suggests that strain A11 carries multiple copies of the RDH gene, whereas strain A1 does not

This conclusion was confirmed by segregation analysis Strains which carry two contiguous copies of a gene segregate clones at a high rate with only one copy[10-13] We examined the frequency at which superproducing strains, which give large colonies on 0 05% xylitol plates, produced small colonies after overnight growth on broth A number of these small colonies was picked and assayed for ribitol dehydrogenase activity after growth on casamino acids and ultrasonication Table 4 shows that about one-fifth of the small clones selected from strain A11 had wild type levels of enzyme, giving a segregation frequency of $1\ 4\times10^{-3}$, whereas strain A1 produced no segregants Reversion of a point mutation would occur at a frequency of about 10^{-6}, so strain A11 carries multiple copies of the RDH gene

Strain A211 appears to carry more copies of the gene than strain A11, since it segregates at a higher frequency (Table 4) Some of the A211 segregants have enzyme levels like strain A11, while others are clearly wild type in behaviour (another class A11/A in Table 4, could not be

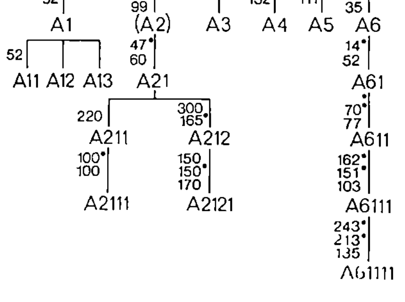

Fig 3 Genealogy of spontaneous and ultraviolet-induced evolvants The strain numbers indicate the evolutionary history of the strain Thus A1 and A2 and so on are derived directly from A, A11 and A12, and so on from A1 The numbers between strains are the generations which elapsed before isolation of the new strain *An ultraviolet mutagenesis

Table 1 Initial experiments to mimic natural evolution performed without mutagenesis

Strain	Apparent μ_m (h^{-1})	Apparent K_m for xylitol in crude extract	Specific activity in crude extract (RHD units mg^{-1} soluble protein)	Apparent K_m for xylitol of pure enzyme	Xylitol ribitol activity ratio for pure enzyme
A	0 53	1 2 M	2 0	1 2 M	0 24
A1	0 64	1 4 M	9 0	1 4 M	0 21
A11	0 82	1 3 M	32 0	1 3 M	0 17
A21	0 64	1 6 M	11 0	—	—
A211	0 84	1 2 M	27 0	1 3 M	0 18

One unit of RDH activity is defined as that amount which reduces 1 μmol NAD min^{-1} in the conditions of the standard assay system, 0 83 mM NAD, 100 mM phosphate buffer, *p*H 7 0, 28° C Apparent K_m values were determined in this system The xylitol ribitol activity ratio is that of the apparent V_{max} on xylitol to the specific activity determined on saturating (50 mM) ribitol

unambiguously assigned as A or A11) These results are those expected if A11 carries two copies of the RDH gene while A211 carries three copies If A211 carried four copies, segregants with an enzyme level between A11 and A211 should have been detected

Comparison of these segregation frequencies with results for duplications of structural genes in *Escherichia coli* suggests that strain A11 may have a duplication covering several genes Segregation frequencies have been measured for *E coli* strains with gene duplications of glycyl-tRNA synthetase[10], glycyl-tRNA[11], tryosyl-tRNA[12 14], and the *lac* operon[15] and the rII region of bacteriophage T4D[13] The segregation frequencies we observe are higher than for strains with a tandem gene duplication[11,14,15], but lower than for strains in which 5% of the genome is duplicated[10] This supposition is supported by the observation that during enzyme purification from strain A11, a second protein was observed to be increased considerably in amount relative to strain A, and acrylamide gels of crude extracts of A11 showed that this protein and ribitol dehydrogenase were present in roughly equal amounts

Table 2 Comparison of RDH purification for strains A, Al and All

Purification step	Total units (× 10^{-5})			Specific activity (RDH units mg^{-1} protein)			Purification			Yield		
	A	A1	A11	A	A1	A11	A	A1	A11	A	A1	A11
Crude extract	1 8	8 8	27 5	1 0	5 1	18 7	1	1	1	100	100	100

G-200 Sephadex eluate	0 45			83			80			26		

The figures for total enzyme units are normalised to a preparation from 1 kg of cells

Why make more enzyme?

We have shown that enzyme superproduction is an invariable response to the selective pressure used under conditions of mild mutagenesis, whether spontaneous or induced by ultraviolet light or nitrosoguanidine (J M Dothie and B S H, unpublished) Figure 2 clearly demonstrates that a mutant with increased specificity for xylitol such as strain B (obtained after powerful nitrosoguanidine mutagenesis[6]) would have taken over from strain A in our chemostats Moreover, the growth rate of strain B on xylitol is the same as that of strains A1 and A21, so it would compete effectively with a first-stage superproduction mutant This phenomenon is not an artefact of chemostat selection since we have also found nothing but superproducers by plate selection on low concentrations of xylitol after mild mutagenesis One must conclude that the frequency of mutations leading to increased enzyme production is much greater than that leading to improved enzyme specificity

The rate of spontaneous mutation to RDH^- for this organism is about 10^{-6} There are 249 residues per chain, thus 250 triplets in the gene and each triplet can yield on average six amino acid replacements by a single base change Therefore the frequency of any particular single-step replacement will be of the order of 10^{-9}, assuming equal mutability across the gene Values of this order have been observed for *E coli* genes, ranging from 2×10^{-10} for streptomycin resistance[16] to 10^{-8} for bacteriophage T1 resistance[17]

We have screened some 10^{14} wild type organisms without detecting mutational alteration of the enzyme's specificity for xylitol If such mutational improvement could result from a single base change it would occur at a frequency greater than 10^{-10} Statistical considerations allow that some mutations will not be detected in the chemostat[3], but we calculate that we should detect around 10% and certainly more than 1% of all events We conclude that no point mutation can lead to a viable enzyme with improved specificity for xylitol

We are forced to conclude that this ribitol dehydrogenase cannot evolve towards a new specificity for xylitol by single step mutations whilst under continuous selective pressure Multiple mutations may, and do (J M Dothie and B S H,

Table 3 Determination of mutation frequencies

Strain	No of xylitol negative clones	No of RDH negative clones	Frequency of RDH negative clones
A	71	43	2 6 × 10^{-4}
A1	30	18	6 0 × 10^{-4}
A11	0	0	<3 0 × 10^{-8}

Each strain was grown on B broth to a density of 2 × 10^8 cells ml^{-1} then washed with and resuspended in Tris-maleate, *p*H 6 0, nitrosoguanidine was added to a final concentration of 0 2 mg ml^{-1} and the culture incubated at 37° C for 30 min The cells were then washed with B broth, diluted 1 20 into the same medium and grown out overnight After being washed with M9 and then starved for 20 min the culture was diluted with M9 to give a density of 10^7 cells ml^{-1} Xylitol was added to 0 2% and benzylpenicillin to 0 6 mg ml^{-1} and the culture was incubated for 4 h Appropriate dilutions were spread on to M9/xylose plates which after incubation were replicated on to M9/xylitol plates

Table 4 Results of segregation experiments

Strain	Small clones (%)	%	Segregants No	Class	
A1	0 03	0	0	—	
A11	0 76	0 14	28	A11	(23)
				A	(5)
A211	0 75	0 68	32	A211	(3)
				A11	(13)
				A11/A	(9)
				A	(7)

After being cloned several times on xylitol, strains were grown on B broth until the optical density at 650 nm was approximately 1 0 Aliquots of a suitable dilution were spread on to M9/0 05% xylitol plates which after incubation were examined and the number of small colonies determined A sample of these small colonies was picked and assayed for RDH level Cultures were grown on 3% casamino acids and the cells were ruptured by treatment with lysozyme/EDTA and Triton X-100 This procedure is as effective at releasing RDH as ultrasonication Extracts were then assayed for RDH activity and total protein and from the specific activities thus determined each clone could be classified

unpublished), produce enzymes with improved specificity, but these would occur spontaneously at a very low frequency—around 10^{-18} Spontaneous steps which increase enzyme level, however, are more frequent—around 10^{-13}—and most of these steps are due to gene multiplication Thus far, therefore, these experimental results are in accord with the evolutionary hypothesis propounded above Further experiments are needed to test the evolutionary pathway of the gene-doubled strains under conditions of fluctuating selective pressure

If it is generally true that multiple mutations are required for evolutionary improvement, then it is likely that such mutations will often be incompatible with the tertiary structure of the protein Evolutionary progress and viability can be reconciled by gene duplication, which allows the second gene copy to accumulate mutations while not immediately constrained by natural selection We have demonstrated that multiple mutations are required for, and gene duplications are a frequent part of, one evolutionary pathway

Opposite conclusions can be drawn, however, from the studies[18] of Clarke and her collaborators on the experimental evolution of an amidase in *Pseudomonas aeruginosa* Whereas the wild type enzyme is specific for acetamide and propionamide, new specificities for butyramide, valeramide, phenylacetamide and acetanilide evolve readily by single mutations We suspect that this apparent contradiction is explained by the fact that we are trying to set a more difficult evolutionary problem for a more complex enzyme a change in stereospecificity about the carbon atom adjacent to the site which donates hydride ion to NAD But the contrast between the conclusions which we draw strongly indicates that the evolutionary potential of an enzyme may itself be a function of its tertiary structure

We thank Sydney Brenner for drawing this system to our attention and for valuable discussion, Chris Bruton for much helpful advice and Denis Herbert for the hospitality of his laboratory and an introduction to chemostat technology B D B is grateful for the award of a Postdoctoral Fellowship by the American Cancer Society, while during part of this work P W J R held a Scholarship from the Medical Research Council

letters to nature

Black holes of small mass

ANY star which has exhausted all of its nuclear fuel and which cannot eject sufficient matter so that its mass becomes less than roughly two solar masses, must undergo gravitational collapse to become a black hole Thus one usually associates black holes with masses of stellar proportions But it is possible that during the initial chaotic conditions of the Universe, black holes of much smaller mass[1,2], down to 10^{-5} g, may have been formed Here we suggest an experiment by which one may detect or set meaningful upper limits to the number density of black holes of small mass (hereinafter referred to as BHSM)

First we estimate the BHSM–Earth collision time, τ, under reasonable assumptions, for various values of the mass *m* of the BHSM Assume the space density of BHSM is ρ g cm^{-3} Because the mass distribution of the BHSM is unknown, we may assume that they all have the same mass *m*, and investigate the consequences of varying the mass Then[3],

$$\tau^{-1} = \pi R_E{}^2 \rho V \left[1 + (V_e/V)^2\right]/m \qquad (1)$$

where R_E is the radius of the Earth, V_e ($\approx 10^6$ cm s^{-1}) is the escape velocity from the Earth, and V the velocity of the BHSM at infinity Because of the solar motion[1] and the Earth s rotation, $V \gtrsim 10^6$ cm s^{-1} So $(V_e/V)^2 \lesssim 1$ and

$$\tau \approx m/\pi R_E{}^2 \rho V \approx 10^{-10}\, m\, (10^7/V)\, (10^{-23}/\rho)\ \text{yr} \qquad (2)$$

The parameter *m* may be varied in order to estimate the maximum possible flux of BHSM and to ascertain whether such a flux is detectable

Highly sensitive superconducting accelerometers[5,6] are now being developed for use in low temperature gravitational wave detectors One of us (D G B) is constructing an accelerometer which is also particularly applicable to the detection of BHSM This accelerometer measures the deflection of a magnetically levitated test object of mass M against a constraining magnetic field Deflections Δx as small as 10^{-17} cm may be detected To detect a BHSM we must observe a differential acceleration of the test mass relative to its support Suppose the accelerometer is supported by a rigid body so that the test mass is at a distance l from the centre of mass C Consider the passage of a BHSM of mass m with speed V_0 at a distance s from the test mass and $(s+l)$ from C Then, neglecting geometrical factors, the test mass gains an impulsive velocity[7] $2Gml/V_0s(l+s)$ relative to C Because the test mass is attached to the accelerometer by a magnetic 'spring' of 'spring constant' $M\omega^2$

$$\tfrac{1}{2} M\omega^2 (\Delta x)^2 = \tfrac{1}{2} M\,[2Glm/s(s+l)V_0]^2$$

so that

$$m = V_0\,\omega\,(\Delta x)s(s+l)/2Gl \tag{3}$$

We note that the mass on which the accelerometer is mounted need not be a gravity wave antenna, and that ω is not related to the frequency of the antenna The strength of the magnetic field may be varied to vary the spring constant $M\omega^2$ The value of ω can vary from 10^{-2} rad s^{-1} to 10^4 rad s^{-1} For greatest possible sensitivity, we take $\omega = 10^{-2}$ rad s^{-1} and $\Delta x = 10^{-17}$ m

For BHSM to be observable, we require a flux sufficient to produce one event per year Setting $\tau R_E^2/ns^2 = 1$ yr in equation (2) we require that

$$m \lesssim 2.4 \times 10^{-8}\, n\, s^2 (\rho/10^{-23})\,(V/10^7) \tag{4}$$

where n is the number of detectors

For simplicity we separate two cases, $s \leqslant l$ and $s > l$ If $s \leqslant l$, equation (3) reduces to $m = \omega(\Delta x)sV_0/2G$ to within a factor of two Now if $V > V_e$ it follows that $V_0 \sim V$ So to detect a BHSM travelling within a distance s it is necessary that

$$m \gtrsim 7.5 \times 10^{-6}\, s\,(V/10^7)\ \mathrm{g} \tag{5}$$

Inequalities (4) and (5) can both be satisfied only if

$$s \gtrsim (3.1 \times 10^2/n)\,(10^{-23}/\rho)\ \mathrm{cm}$$

If the apparatus is to be isolated, l is restricted to about 10^3 cm Taking $s \leqslant 10^3$ cm and choosing $n = 100$ it follows that

$$\begin{aligned} 2 \times 10^{-5}\,(10^{-23}/\rho)\,(V/10^7) \lesssim m \lesssim\ & \\ 2(\rho/10^{-23})\,(V/10^7)\ & \end{aligned} \tag{6}$$

So the range of masses that can be detected depends on ρ and V We note also that equation (6) can be satisfied only if $\rho \gtrsim 10^{-25}$ g cm^{-3} It is likely that during the early history of the Universe BHSM became concentrated into galaxies with a space density ρ_G An upper limit[8] for ρ_G in the solar neighbourhood is about 10^{-23} g cm^{-3} If ρ_G equals this upper limit and $V \sim 10^7$ cm s^{-1}, masses in the range 10^{-5} to 1 g may be detected

If the Earth itself is the supporting mass $l = R_E$ Taking an upper limit for s of 10^8 cm one requires that $\rho \gtrsim 10^{-30}$ g cm^{-3} If ρ_c be the cosmological space density of BHSM then[2], $\rho_c \lesssim 10^{-28}$ g cm^{-3} If this upper limit is attained and $V \sim 10^7$ cm s^{-1}, masses in the range 1 to 10^5 g may be detected In this case narrow band filtering of the seismic noise at the frequency corresponding to the interaction time of the BHSM would be necessary in order to reduce the noise level Such filtering could be difficult

For the case $s > l$, from equation (3) we have that $m \approx \omega(\Delta x)V_0s^2/2Gl$ to within a factor of two, so that masses in the range

$$\begin{aligned} 7.5 \times 10^{-6}\,(V/10^7)\,s^2/l \lesssim m & \\ 2.4 \times 10^{-8}\, ns^2\,(\rho/10^{-23})\,(V/10^7) & \end{aligned} \tag{7}$$

may be detected provided $\rho/10^{-23} \gtrsim 3.1 \times 10^2/nl$ For example if $n = 100$, $l = 10^3$, $V = 10^7$ cm 5^{-1} and $s > 10^3$ cm, BHSM can be detected if $\rho \gtrsim 10^{-26}$ g cm^{-3}

We now consider whether BHSM can be concentrated within the Solar System through gravitational interaction with a planet such as Jupiter This could give rise to an even larger flux of BHSM The collision time τ_J of a BHSM with Jupiter is obtained by multiplying equation (2) by $(R_E/R_J)^2$ where R_J ($\approx$ 0.3 AU) is the radius of the sphere of influence[9] of Jupiter So

$$\tau_J = 2 \times 10^{-18}\, m\,(10^7/V)\,(10^{-23}/\rho_G)\ \mathrm{yr} \tag{8}$$

Thus frequent collisions are possible for reasonable parameters in equation (9) Suppose that a (net) fraction α (V) of BHSM coming within the sphere of influence of Jupiter are captured by the Solar System The contribution of these BHSM to the solar system density is

$$\begin{aligned} \rho_S &= \alpha\,(5 \times 10^9/\tau_J)\ [3\,m/4\pi\,(7.5 \times 10^{13})^3] \\ &\approx \alpha\,(V/10^7)\,(\rho_G/\,10^{-23}) \times 10^{-15}\ \mathrm{g\,cm^{-3}} \end{aligned}$$

The value of $\alpha(V)$ is difficult to estimate, but, if $\alpha \gtrsim 10^{-8}$ some increase in ρ_S over ρ_G can be obtained But $\rho_s \lesssim 10^{-18}$ g cm^{-3}, since otherwise perturbations of spacecraft would have been discovered It has been suggested[10-12] that the Tunguska meteoric event was caused by a black hole of mass $\sim 10^{21}$ g We note that even if $\rho_s = 10^{-18}$ g cm^{-3}, such an event was an extremely rare occurrence (equation (2))

The trajectory of a BHSM can be roughly estimated by utilising the uniaxial directional properties of the accelerometer[5,6] Two detectors properly oriented could distinguish between particles moving up or down Since BHSM can travel through the Earth whereas meteors cannot, those particles travelling upwards must be black holes

Particle acceleration in planetary magnetospheres

MEASUREMENTS of energetic particle fluxes in space[1,2] have stimulated interest in the problem of particle acceleration inside planetary magnetospheres Suggestions that terrestrial auroral (keV) electron precipitation is associated with transient space charge effects[3], have been discarded, largely because the parallel (plasma) electrical conductivity ($\sigma_{\parallel}$) is so large that magnetospheric field lines are constrained to remain equipotentials[4]

Here I point out that planetary magnetospheric field lines are not constrained to remain equipotentials when the plasma conductivity ($\sigma_{\parallel}$) is dominated by current driven microinstabilities as opposed to electron-ion collisions For example in the 'collision-free' regime defined by $c_s \leqslant u_{\parallel}^- \leqslant v_{Te}$ and $T_e \gg T_i$, the plasma conductivity $\sigma_{\parallel}$ is determined by the spectrum of unstable ion-sound waves The measured value is [5]

$$\sigma_{\parallel} \simeq \omega_{p_e}(4\pi \times 10^8)\ \text{mho m}^{-1} \qquad (1)$$

$c_s \equiv \sqrt{(kT_e/M_i)}$=ion-sound speed, $v_{Te} \equiv \sqrt{(2kT_e/m_e)}$=electron thermal velocity, $u_{\parallel}^-$=relative drift velocity between the electron and ion populations, $\omega_{p_e} \equiv \sqrt{(n_e e^2/\varepsilon_0 m_e)}$=electron plasma frequency

If $n_e \sim 10^8$ m^{-3}, $T_e \sim 10$ eV and $u_{\parallel}^- \sim v_{Te}/20$ (where $u_{\parallel}^-$ is induced by transient space charges) then the associated electric field $E_{\parallel}^{(0)} = en_e u_{\parallel}^-/\sigma_{\parallel} \sim 4 \times 10^{-3}$ Vm^{-1} For a flux tube or magnetic field line of length $l \sim 5 \times 10^8$ m (such as a Jovian dipole field line at $L \simeq 3$) the parallel potential $\phi_{\parallel}^{(0)}$ between the equatorial and ionospheric regions is very high, $\phi_{\parallel}^{(0)} \simeq E_{\parallel}^{(0)} l \sim 10^6$ V

The low parallel electron mobility (equation (1)) is the result of resonances between the current carrying electrons and the unstable, current driven, ion-acoustic modes[6], in fact an 'effective' collision frequency (Ω), due to the turbulent electrostatic ion-sound fluctuations, can be defined where[6]

$$\Omega = (2\pi e^2/u_{\parallel}^- \varepsilon_0 n_e m_e^2)\Sigma(\mathbf{k}/k^2) W_k \int d^3\mathbf{v}\mathbf{k}\,(\partial f_i/\partial \mathbf{v})\,\delta(\omega - \mathbf{k}.\mathbf{v}) \qquad (2)$$

W_k=electrostatic energy per unit volume in the mode $\mathbf{k}$, $\delta(\omega - \mathbf{k}\,\mathbf{v})$ indicates wave-particle resonance, the rest of the notation is standard Because ion-sound turbulence is not isotropic, however, a small fraction δf_e of the electron population is not in resonance with the unstable modes and consequently it is not included in the summation (2) The number density of this component for a 'shifted' Maxwellian

$$f_e = n_e(\beta/\pi)^{3/2} \exp - \beta[v_{\perp}^2 + (v_{\parallel} - u_{\parallel}^-)^2]$$

(with $\beta \equiv m_e/2kT_e$) is

$$\delta n_e = \int d^3 v \delta f_e$$

$$= n_e(\beta/\pi)^{3/2} \int_0^{2\pi} d\theta \int_{-\infty}^{+\infty} dv_{\parallel} \int_0^{v_{\parallel}\alpha} dv_{\perp} \exp - \beta\left[v_{\perp}^2 + (v_{\parallel} - u_{\parallel}^-)^2\right]$$

$$\simeq (n_e/2)(c_s/u_{\parallel}^-)^2 \qquad (3)$$

(with $\alpha \equiv \sin^{-1}(c_s/u_{\parallel}^-)$)

Assuming that the turbulent electric field $\mathbf{E}^{(1)}$ experienced by the nonresonant electron component δf_e is stochastic, their motion can be described by a Fokker–Planck equation Further, provided that $\langle \mathbf{E}^{(1)}(r_0(t),t) \rangle = 0$, ($r_0(t)$=unperturbed particle trajectory and $\langle\ \rangle$ indicates an ensemble average) the Fokker–Planck equation can be reduced to a simple diffusion equation

$$\{\partial/\partial t + v_{\parallel}\,\partial/\partial r - (e/m_e)\,E_{\parallel}^{(0)}\,\partial/\partial v_{\parallel}\}\delta f_e = \partial/\partial v_{\parallel}\,(D\partial/\partial v_{\parallel}\,(\delta f_e)) \qquad (4)$$

(D=velocity space diffusion coefficient due to the turbulent fluctuations)

It is apparent from equation (4) that the nonresonant component δf_e retains its high parallel mobility and in spite of the turbulence these electrons essentially free fall in the large electric potentials $\phi_{\parallel}^{(0)}$

The combination of high parallel electric potentials $\phi_{\parallel}^{(0)}$ (due to 'anomalously' low conductivity effects) and a tenuous but highly mobile electron component δn_e (due to the nonisotropic nature of ion-sound turbulence) provides an important mechanism for generating sporadic and stormy outbursts of energetic electrons inside planetary magnetospheres

High power acoustic radar

THE range and sensitivity of turbulence detection by acoustic probing of the lower atmosphere initiated by McAllister *et al*[1] has in part been restricted by the use of low power acoustic pulses (generally ~ 100 W) We shall briefly describe a pulsed high power (8 1 kW input) sound

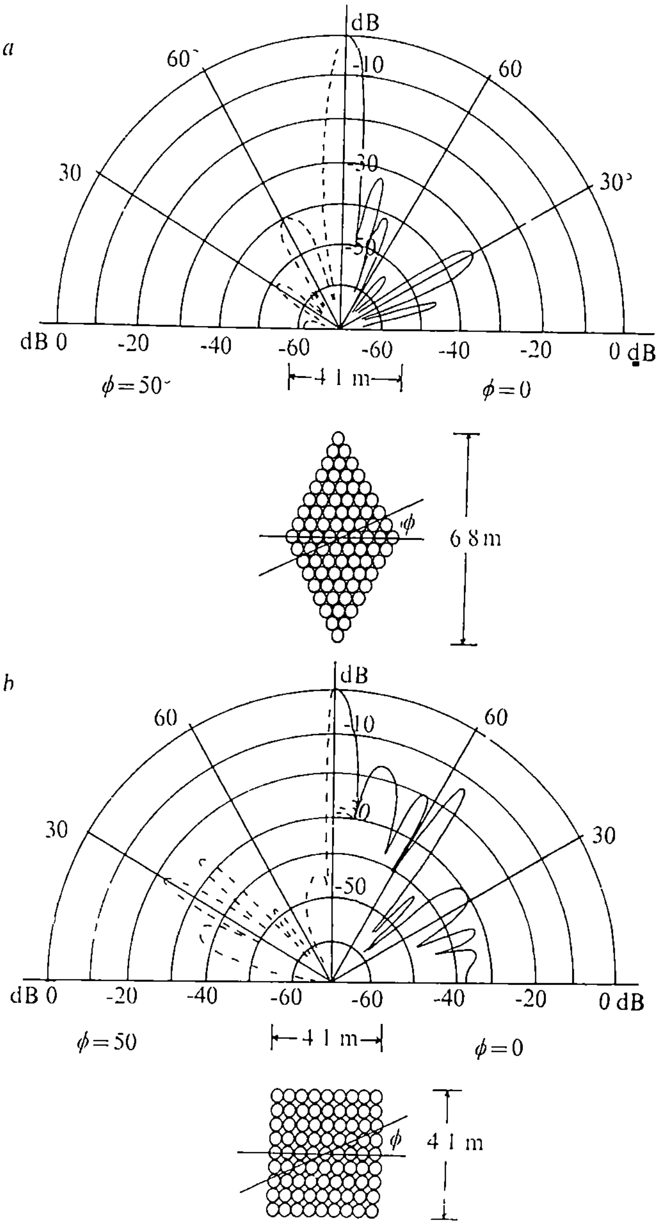

Fig 1 Radiation patterns for, *a* diamond and, *b*, rectangular arrays at 1,305 Hz The solid curve represents half the cross section at φ =0° and the dotted curve is half the cross section at φ =50°

radar system and present representative data obtained with a 2 7 kW system

An all-weather capability coupled with a high degree of system reliability and flexibility was essential The limitations[2] to an acoustic radar and cost estimates led to a suitable operation frequency of approximately 1 kHz

A high gain array was selected as the transmitter antenna An individual transmitter array element consisted of a bin, resonant at a suitable frequency fed by an inverted 100 W electrodynamic transducer exponential horn combination (approximately 50% efficient) These transducers had proven reliabilities and the unit inversion provided the necessary transducer weather protection

Various array configurations were numerically simulated to determine an optimum narrow beamwidth or gain and side-lobe level appropriate for an acceptable amount of noise pollution An 81 element diamond-shaped array was finally selected and its beam pattern, shown in Fig 1, indicates that this design has better side-lobe characteristics than a conventional rectangular array The fact that the beam pattern is not symmetrical is not of any serious consequence Note that only two cross sections are shown and that the patterns presented consist of the calculated space factor (array beam pattern) multiplied by the measured radiation pattern of an individual array element The actual radiation pattern of the array has not yet been measured and effects such as atmospheric turbulence upon the beamshape are unknown To further improve side-lobe levels, the entire transmitting array was placed in a hole 8 feet deep Each array element will finally be driven by a separate 100-W audio amplifier, giving a total power input of 8 1 kW The results presented here were obtained with a power input of 2 7 kW

The receiving system uses a fibreglass parabolic dish, 5 feet in diameter, incorporating a transducer–horn element as the primary feed This provides a broad receiving beamwidth and thus lessens signal loss due to translation of the sound pulsed by the mean wind profile The dish was placed in a separate hole 8 feet deep (located 40 feet from the centre of the transmitter array) to isolate the receiver from wind noise and general background surface interference A low noise preamplifier and narrowband tuned receiving system was used to amplify the acoustic returns and after detection a signal proportional to the logarithm of the detected signal was used to intensity modulate a chart record Provision was made to vary the sensitivity of the receiving system as a function of time after the transmitted pulse, thus reducing the range of intensities that need be recorded

The system was located in flat open country at Laverton, Victoria, which is traversed by the easterly flow of high pressure and cold front systems which pass across southern Australia The results presented provide a typical cross section of records obtained during the period from mid December 1973 to mid February 1974, when the frequency of operation was 1,350 Hz, the bandwidth 5 Hz, and the pulse length 0 4 s

The record shown in Fig 2*a* was obtained after a cold front had passed the site The development of rising echo structures is a characteristic typically associated with a cold front, in this example the highest echo is observed at a range of 9,500 feet at 0000 EST From 0330 EST, at 7,000 feet an echo associated with subsidence inversion conditions is apparent The arrowed bands represent periods during which the noise created by rainfall saturated the receiving system Conditions during the approach of the centre of the following high pressure system are presented in Fig 2*b* The existence of a high degree of turbulence between the ground and the subsidence inversion is clearly indicated even during the night From 0800 EST with the advent of surface heating, plume activity developed which was capped by the inversion at 4,300 feet

A brief assessment of the relative merit of a 100-W input acoustic sounder compared with the high power sounder is shown in Fig 2*c* The system parameters lead to the high power radar having a signal-to-noise ratio (voltage) gain of approximately 10 over the low power sounder, and for the purposes of demonstration, the whole system was switched between power inputs of 100 W and 2 7 kW Every 2 h the system operated in the low power

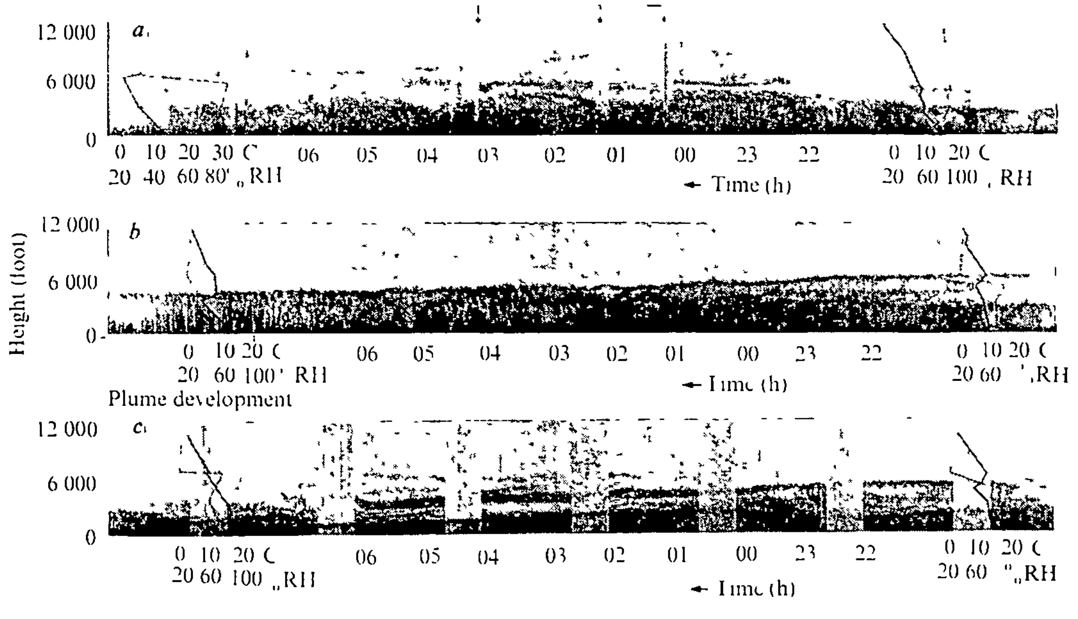

Fig 2 High power acoustic radar record, *a*, obtained after the passage of a cold front on December 16, 1973, *b*, showing night-time turbulent structure during subsidence conditions on December 18, 1973 *c*, Record demonstrating the increased sensitivity of the 2 7-kW input acoustic radar in comparison with the 100-W acoustic radar on February 9, 1974 The abscissa represents time (increasing from right to left), the ordinate represents echo range and the intensity represents the strength of the acoustic return Every half hour range marks at intervals of 500 feet are superimposed upon the record Standard 0815 FST and 2015 FST Weather Bureau radiosonde temperature (solid line) and relative humidity (RH) (dotted line) profiles have also been placed on the records for comparison

mode for a half-hour period (as from 0215 to 0245 EST) This record obtained during high pressure conditions clearly shows a substantial echo regime not indicated by the lower power unit

These preliminary results clearly demonstrate the increased potential of high power acoustic probing The extension to full power of 8 kW will allow the sounder to be used for high resolution acoustic sounding as well as for studying the effects of nonlinear sound propagation in the atmosphere By measuring the change in reflection of electromagnetic energy due to the high power sound slightly altering the dielectric constant of the air, the derivation of temperature profiles is also feasible

This work was supported in part by an ARGC grant and T D K received financial assistance from a Commonwealth Postgraduate Award We thank the Commonwealth Bureau of Meteorology for the use of their radiosonde data

Diurnal change in the location of scintillations in the F-region of the ionosphere

FIELD-aligned irregularities in the F-region of the ionosphere cause amplitude and phase scintillations of satellite radio transmission[1-5] It seems that scintillations increase in magnitude and number towards the northern and southern auroral zones The latitudinal variation is, however, masked by the enhancement of scintillations whenever the angle between the ray path and the magnetic field—the aspect angle—is small Thus, at recording stations from subauroral[4,6] to low[2] latitudes, strong scintillations are observed towards the equator

So far, studies of the amplitude and phase of the scintillations have used VHF beacon transmissions from one or two satellites, and, consequently, consecutive radio scans of the local ionosphere have been relatively infrequent It has therefore been difficult to trace changes in the location of regions of scintillation, at short time intervals Here, I discuss the advantages of using a multisatellite radio transmission system for detecting changes in the location of scintillations at night

The study was based on recordings of the amplitude of radio signals from five United States Navy Navigational Satellites (NNSS) transmitting at a frequency of 150 MHz The satellites move along polar orbits and provide frequent radio scans of the local ionosphere The recording station was situated at Brisbane (27°S, 152 9°E, and 35 8°S geom lat) The receiving antenna had a broad, isotropic beamwidth pattern which made it possible to record satellite passes at high zenith angles of up to 90° As amplitude scintillations at Brisbane are mainly a night time phenomenon[1,2] the recording period was largely limited to a time interval from 1800 to 0500 LT It was possible to record, on average, seven NNSS passes during this time interval Between November 22, 1973 and January 16, 1974, 347 satellite passes were recorded

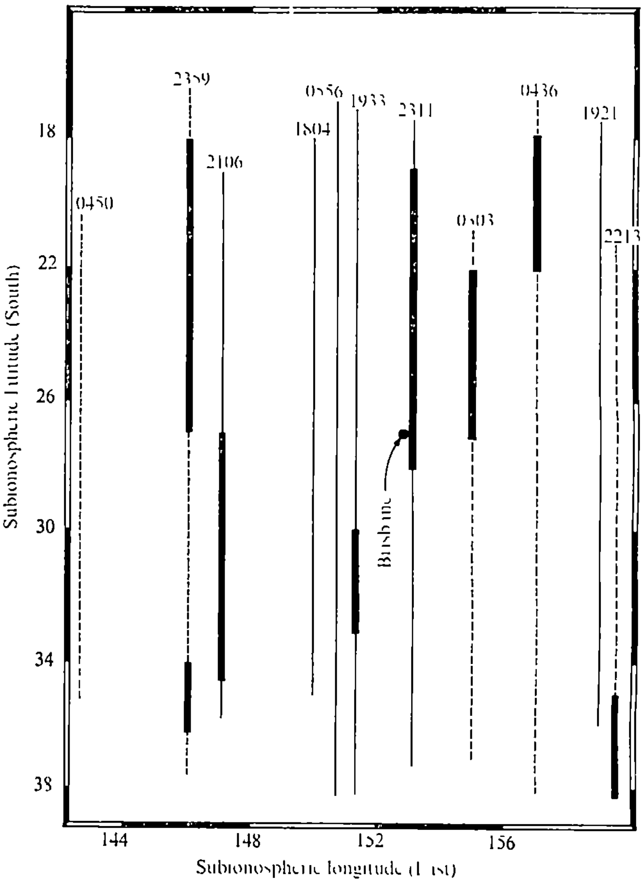

Fig 1 Subionospheric orbits of NNSS satellites Solid line, Night of December 7–8, 1973, broken lines, night of January 8–9, 1974, thick solid lines provide an indication of the horizontal extent of the scintillations The time of the nearest satellite approach (150° EST) is indicated for each pass (LT)

Consecutive radiosatellite scans of the local ionosphere at a height of 400 km were obtained on two nights December 7–8, 1973 and January 8–9, 1974 (Fig 1) It can be seen that the passes recorded at 1804 and 1921 LT on the first night did not reveal any scintillation activity A pass at 1933 LT indicated, however, the presence of a well developed scintillation region polewards of the station Subsequent scintillations at 2106 LT extended more towards the equator Finally, strong scintillations extending well towards the equator were recorded at 2311 LT No scintillations were detected during a morning pass, at 0556 LT A similar development in the location of scintillations was evident during the second night Then, the first recorded pass at 2213 LT indicated scintillations towards the pole The second pass, at 2359 LT, indicated the presence of two scintillation regions towards both the equator and the pole with respect to the station Scintillation activity was limited to regions between the station and the equator during subsequent passes at 0303 and 0436 LT No scintillations were detected during a pass at 0450 LT

The development of scintillation activity tended to follow the pattern shown in Fig 1 Thus, scintillations during the evening occurred between the station and the pole, at high zenith angles Later, but still before midnight, the scintil-

Table 1 Number of nights during which displacements in the location of scintillations were observed

	Time (150 EST) of scintillations	
	1800 – 2400	0000 – 5000
Displacement towards equator	22	4
Displacement towards pole	2	1

lation regions split one remained towards the pole, at somewhat lower zenith angles and the other region shifted towards the equator Finally, scintillation towards the equator became predominant during the morning hours

Table 1 shows the number of nights on which displacement of scintillation regions towards the equator occurred In all but four cases the displacement of scintillations towards the pole, occurred before midnight LT The number of displacements towards the pole is also shown It can be seen that scintillations were first recorded between the station and the equator and were noted subsequently polewards of the original position, the reverse trend was infrequent (Table 1)

The presence of scintillations at high zenith angles and polewards of the recording station is a common phenomenon for Australian stations[2] The spatial effect seems to be strongly dependent on azimuth, and indicates a distinct ridge in scintillation activity This work shows that the polewards ridge structure may drift towards the equator during the evening hours A similar scintillation drift was found in the northern hemisphere by Kersley *et al*[6] who reported that F-region scintillations moved towards the equator between 1500 and 0200 LT

It is likely that the scintillations near the pole are associated with field-aligned irregularities at higher latitudes These irregularities cause pronounced scintillation effects once they have drifted to the position at which the aspect angle is small

A modified predrift fit of Greenland and western Europe

THE most commonly used predrift fit of north-western Europe against Greenland is based on a least squares fit of the Continental crustal edges which are assumed to follow the 500 fathom submarine contour[1] Recent geophysical studies in the North Atlantic and the Norwegian Sea have established a number of facts bearing directly on the Palaeocene palaeogeography of these areas, and on departures of the continental crustal edge from the 500 fathom contour

The whole of the Rockall–Hatton Plateau is a submerged continental fragment[2] Subsidence of this area commenced in the late Palaeocene (56 Myr BP) and the basement dropped to 600–700 m below sealevel by early Eocene times[3] (51 Myr BP) The topographic expression of the western edge of the plateau is closely coincident with anomaly 24 (60 Myr BP) indicating that rifting between Greenland and Rockall began at this time

The Rockall Trough came into existence before late Senonian times, that is, before anomaly 32 (78 Myr BP), (ref 3) Whether the Rockall Trough owes its origin to seafloor spreading or to subsidence of a continental block remains an unresolved question but it is now certain that it was in existence for at least 18 Myr before any spreading on the Reykjanes Ridge, and probably for a great deal longer

There is a gap of approximately 100 km between the continental slope of Greenland (marked by the 1,000 m contour) and the western limit of the oceanic crust (marked by anomaly 24)[3] in the area south of latitude 55°N This may be interpreted in three ways either the intervening area is one of subsidised continental crust, or there is older oceanic crust between anomaly 24 and the continental slope and therefore an extinct spreading axis which is not in evidence elsewhere in the North Atlantic, or this area was produced by some other, unknown process The first of these hypotheses seems the most conservative

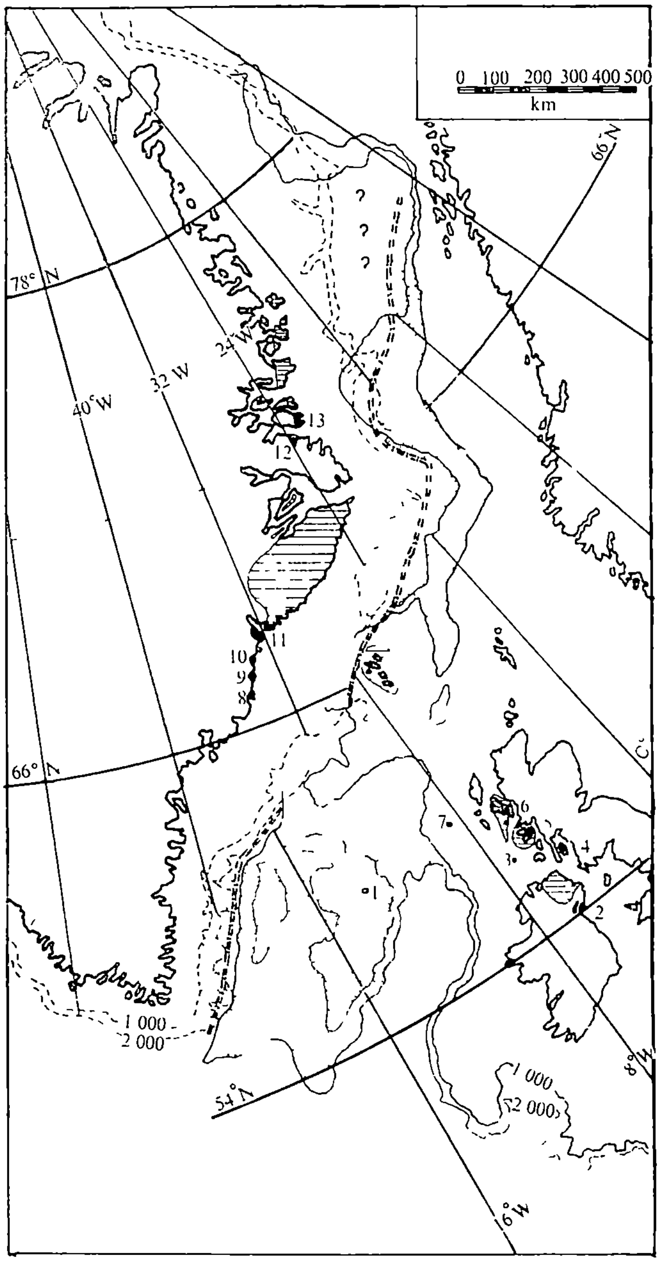

Fig 1 Predrift reconstruction of Greenland and Europe Stippled areas, subsided continental crust, ruled areas, tertiary flood basalts, – – –, 1,000 and 2,000 m bathymetric contours around Greenland, ——, 1,000 and 2,000 m bathymetric contours around Europe, = =, geophysically defined continental margin Tertiary plutonic bodies and ring complexes are numbered 1, Rockall, 2, Mourne 3, Blackstones Bank, 4, Arran, 5, Mull, 6, Skye, 7, St Kilda, 8, Cape Gustav Holm, 9, Nualik, 10, Idglutarajik, 11, Skaergaard, 12, Werner Bjerge, 13, Cape Simpson

in the light of available data from the North Atlantic, and so the continental margin of Greenland is assumed to be coincident with anomaly 24 in this region

The Faeroe Islands are underlain by continental crust[4] The junction of the continental crust and the anomalous crust of the Iceland–Faeroe Rise lies approximately 50 km north-west of the Faeroes and is marked by a large gravity anomaly[5,8]

The magnetic 'Quiet Zone' of the eastern Norwegian Sea is underlain by deeply subsided continental crust[7,8] Between 64°N and 68°N the continental edge is well defined by gravity highs immediately to the seaward side, which are coincident with the limit of magnetic strip anomalies in the area South of this region, however, the edge is less well defined and is now considered to be at the limit of definable strip anomalies

Using available information on the geophysically defined continental edge, I have attempted another fit (Fig 1) This is a subjective reconstruction based on the criterion that areas of known or suspected continental crust should not overlap The only area in which the margins of the continental masses on opposite sides of the Atlantic are well defined is in the region south of Iceland where anomaly 24 is composed of linear features[3] When these predrift isocrons are superimposed the model has only one degree of freedom—relative movement is restricted to a direction parallel to the linear features Further north, the Jan Mayen and Greenland Fracture Zones apply a restraint to this movement, because the fit must bring into juxtaposition those portions of the features closest to the continents Thus, the obtained fit has geological rather than statistical significance In this case the lack of reliable data concerning the position of the continental margin of Greenland north of the Iceland–Greenland Ridge means that objective geometric methods cannot be used to obtain a fit In this context the large gap created by this reconstruction north of latitude 68°N is not considered as a major obstacle, because it may imply that the continental margin of Greenland in this area has subsided in a manner similar to its Norwegian counterpart

The new fit differs significantly from that of Bullard *et al*[1] in that it involves a shift of Greenland some 400 km to the south-west This brings the Tertiary volcanic province of eastern Greenland into close juxtaposition with the Faeroe Islands and on to the extension of the trend of the Faeroe–Hebridean igneous province, to which it shows both temporal and petrological links This close spatial relationship supports the suggestion implicit in Holmes'[9] original definition of the Brito-Arctic Province the rocks are derived from a common source not directly related to other volcanism along the North Atlantic Ridge system If Iceland is the surface expression of a mantle plume or 'hot spot'[10-12] which has maintained a fixed position on the Mid-Atlantic Ridge throughout the last 60 Myr (ref 13) then the traces of the Iceland–Faeroe and Iceland–Greenland Aseismic Ridges should define the relative movement of the continental masses, and any predrift fit constructed on this basis would, necessarily, place the Faeroes opposite the Kangerdlugssuag region of Greenland

Mesozoic stratigraphy and tectonic patterns in eastern Greenland[14] and north-western Europe show remarkable similarities[15], and the trend of the North Sea Graben, well defined by the major petroleum finds of the area, is coincident with the trend of the Mesozoic graben structure of eastern Greenland (Fig 2) Although the thickness[18] of sediment in the North Sea (up to 8 km) is considerably greater than in Greenland, much of this is of Tertiary age and the thickness of Mesozoic sediment (approximately 4 km) is more closely comparable to that of Greenland If these structures form a truly continuous belt then they cut across the subsequent rift system of the North Atlantic, and the view that the Mesozoic and Tertiary basins of north-western Europe are, in a simple way, related to this incipient rift must be examined more closely[17-19]

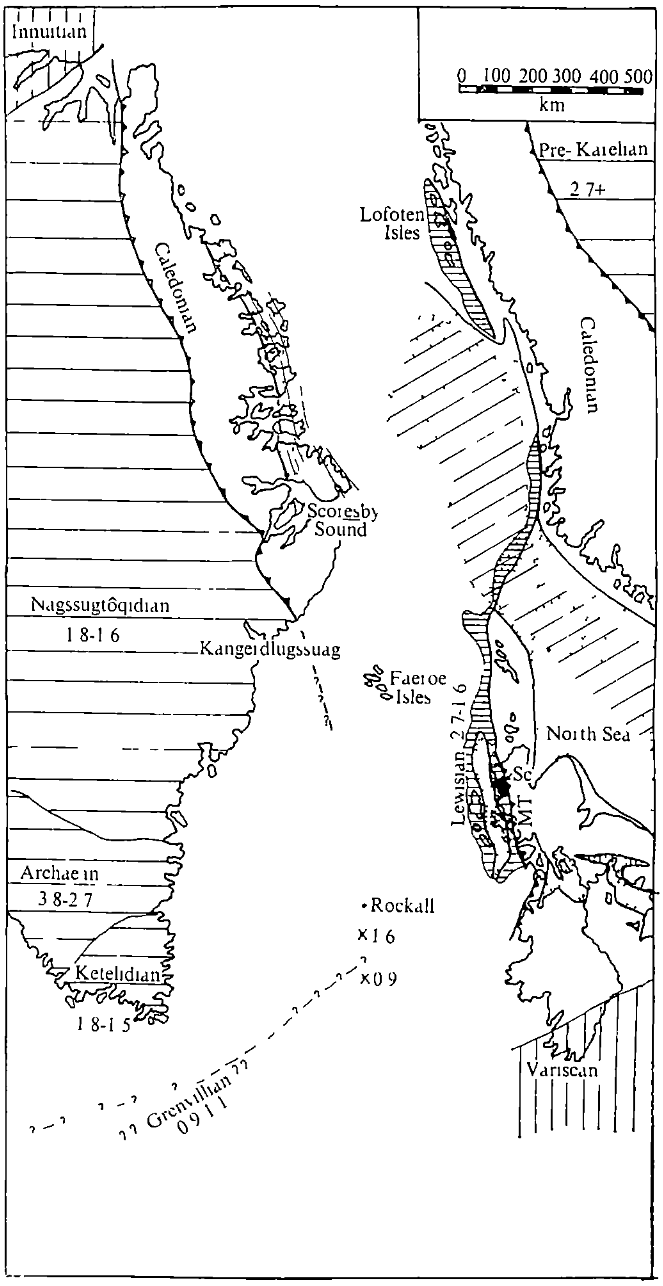

Fig 2 Major geological features of Greenland and north-western Europe Horizontal ruling, pre Caledonian orogenic belts showing radiometric ages (×10⁹ yr), vertical ruling, post-Caledonian orogenic belts, stipple, Mesozoic basins, Sc, Scourian, MT, Moine Thrust, ×, drill sites on the Rockall Plateau, with radiometric ages (×10⁹ yr)

The difficulty of aligning the Caledonian Front of Greenland[14] with the Moine Thrust Zone of north-western Scotland has been cited as criticism of the Bullard fit[20] But this was overcome to a large extent, by Bott and Watts[21], whose reconstruction produced a reasonable alignment of these features The present model, however, is not compatible with the alignment of these two structures (Fig 2) An examination of the geophysical evidence concerning the north-eastward extension of the Precambrian basement of north-western Scotland[22,23,8] strongly suggests that it takes the form of a discontinuous basement ridge trending NNE and eventually reappearing in the Lofoten Islands The basement complex of the Lofoten Islands has a radiometric history similar to that of the Laxfordian of Scotland[24,25] The published ages of rocks drilled from the Rockall Plateau[26,27] do little to clarify the position of the southerly continuation of the Caledonian Front from Greenland The date of 989 ± 5 Myr from one of the samples (Fig 2), assumed to be Grenvillian, is, however, similar to dates from immediately south-west of the Caledonian Front in Greenland[28]

The suggestion that the Precambrian histories of Scotland and Greenland are directly comparable and that the Scourian is the lateral equivalent of the Archaean of Greenland[29] requires further corroboration in view of the fact that these two regions must, on the reconstruction presented here, be assumed to be separated by the western half of the Caledonian Mountain Belt

The Burtle Beds of Somerset—glacial or marine?

KELLAWAY[1] described the Burtle Beds as "residual masses of glacial sand and gravel ('Burtle Beds'), (which) rise out of the marshes at Catcott Burtle, Weston Zoyland and Othery" Kidson and Haynes[2] supported the earlier view of Bulleid and Jackson[3] that the deposits are of marine origin and of interglacial rather than glacial age and provenance They concluded that "any suggestion that the Burtle Beds are ice transported is quite untenable A fluvioglacial origin is so unlikely as to be unacceptable "

As evidence for a marine origin Kidson and Haynes showed that the microfauna indicate a transgressive estuarine–marine phase The sands and gravels rest conformably on clays of similar age and origin which were clearly laid down in the same transgression The clays in turn rest on a hard fissile clay interpreted as Lower Lias Hawkins and Kellaway[4], in reply, found "nothing to convince us of the marine origin of the Burtle Beds or to change our opinions of the older glaciations" They suggested that the clay beneath the sand described by Kidson and Haynes was "remoulded Lower Lias clay contaminated with microfossils or ground up shell debris,

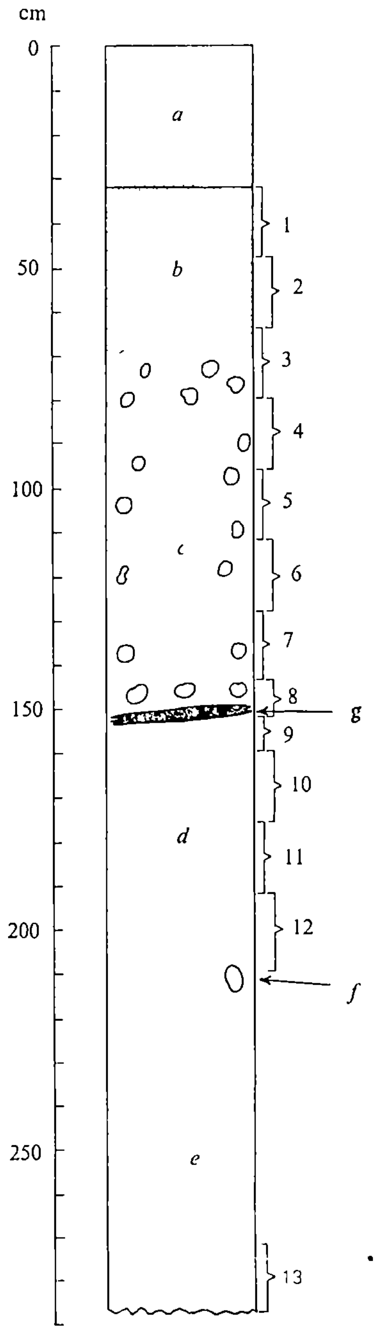

Fig 1 The section exposed in a pit at Hill Farm, Catcott Burtle *a*, Sandy soil, *b*, sand, *c*, brown clay with stones and occasional shells, *d*, hard fissile blue yellow clay, *e*, hard fissile blue clay, *f*, *Paltechioceras elicitum* (ammonite), *g*, *Corylus* (recumbent branch?) Numbers refer to samples (see Fig 2)

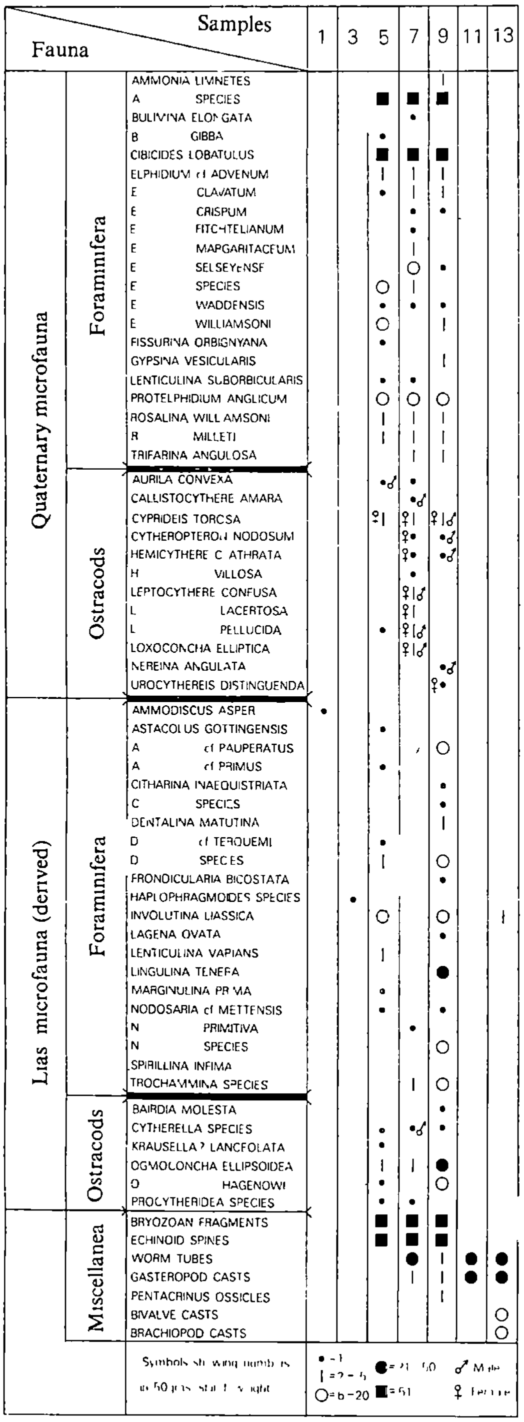

Fig 2 The distribution of fauna in the samples from Hill Farm, Catcott

some having been carried by water draining from the overlying Burtle Beds in the boreholes"

To test this argument, we dug a pit with a mechanical excavator so that samples could be obtained from a clean face where any possibility of contamination could be ruled out The pit was sited midway between boreholes 8D and 8E (Fig 2 of ref 2) at Hill Farm, Catcott Burtle (ST399430) The stratigraphy revealed is shown in Fig 1 At the passage between the two clays was a branch, root or trunk of *Corylus* (hazel), not in a growth position, which yielded a ^{14}C date of 4,280±70 b p (HAR 463) The face was sampled as indicated in Fig 1, and alternate samples were examined for microfauna (Fig 2) The results clearly confirm previous observations[2] first, that the microfauna in the Burtle clay (the upper brown clay) is a mixture of Quaternary and Liassic species with other time periods apparently unrepresented, second that there are no exclusively cold water Quaternary species, and finally that the overall aspect is consistent with estuarine accumulation The samples were also examined for pollen, but it has proved impossible to date this or other 'Burtle Bed' deposits by pollen analysis

When the distribution chart is considered in detail and compared with that for the boreholes previously examined (Fig 3 of ref 2) the close similarity of the microfaunas, particularly with 8D, is apparent, allowing for name changes in some of the ostracods, because of generic shifts[5] [6]

The deposit from which the name 'Burtle Beds' was derived is thus clearly seen at Catcott Burtle to be of estuarine–marine origin and to include Quaternary clays beneath the sands and gravels, as suggested earlier[2]

A completely new element has appeared, however, because of the discovery of *Corylus* in the pit at Hill Farm The wood occurs immediately above the passage horizon represented by sample 9 (Fig 1) If the Burtle clays were of Pleistocene age, an infinite ^{14}C age could be expected The Holocene date can only mean, however, that the overlying deposits were emplaced in the late Holocene A sand–intertidal silt relationship, similar to that at Hill Farm, is evident in an excavation for a new road bridge near Penzoy Farm (ST337349), (D D Gilbertson, personal communication) A sample of wood from Penzoy Farm is now being dated, but preliminary results suggest a similar Holocene age An examination of the altitude of the wood samples at Hill Farm and Penzoy Farm (3 5 m OD), which may be either *in situ* or driftwood, in relation to Flandrian sealevel curves for the area[7] suggests strongly that these sites were coastal towards the end of that transgression They therefore cannot now be regarded as typical Burtle bed sites It is possible that these sites are of interglacial age, and were modified in post-glacial times It is interesting to note, in retrospect, that Ussher[8] discussed and rejected the possibility of a Flandrian age for the beds

The division into a sand layer, and an underlying clay bed of similar age, arrived at on the basis of borehole evidence, has been demonstrated in an open face at Hill Farm, Catcott Burtle, eliminating the argument about contamination A comparable division was revealed in a pit at Greylake There can be no doubt about the Interglacial age of these deposits If the sands and gravels at Catcott Burtle were originally of true Burtle Bed type comparable to those at Greylake, they must have been reworked, at least on the margins, by the Flandrian sea The microfauna includes forms[2] that are known from the Flandrian and Recent of Great Britain and also occur in the last interglacial (Ipswichian) The Catcott Burtle fauna does, however, include northern forms, *Elphidium clavatum* and *Hemicythere clathrata,* and a southern form *E fitchtelianum,* which lends slight support to the idea of reworking On the other hand these deposits may be truly of Flandrian age and unrelated to what are now called Burtle Beds elsewhere in the levels

These conclusions do not call into question the age or origin of the mass of the Burtle Beds No evidence has yet been produced on which to justify a glacial or fluvioglacial origin for them All the available evidence[2], including the pre-Flandrian shell dates from Mollusca from the Burtle sands and gravels south of the Poldens[9] points to a marine interglacial, probably Ipswichian, origin The problem remains of separating the undisturbed deposits of Burtle sands and gravels from the deposits of the Flandrian sea or from earlier marine beds reworked by that sea That now seems to have washed not only islands and peninsulas of Lias and Trias, but also of Burtle sands and gravels On the basis of height alone, most of the sand batches north of the Poldens and perhaps many of those to the south must be re-examined More detailed study is called for than has yet been attempted A beginning is being made with a detailed re-examination of the deposits of Greylake

Dr R C Whatley identified the ostracods, and the results were discussed with Dr Alan Lord (University College London), Dr C G Adams (British Museum, Natural History) and Mr Ben Johnson (Arco Petroleum Co) kindly examined and commented on the Liassic foraminiferal fauna

Dating of the rock succession containing fossil hominids at East Rudolf, Kenya

THE geology of the large complex faulted depression between the Ethiopian and Kenyan rifted, upwarped domes, is virtually unknown in detail Up until 1969 there had been only a few isolated expeditions[1-4] into the region, but since then there has been an increased amount of research around Lake Rudolf, particularly by Kenyan, American and French based workers[4] It has been shown that the sparsely inhabited semi-desert area to the east of Lake Rudolf is exceptionally rich in the remains of fossil man, and there is abundant evidence of his activities[5-28] informative hominid assemblages have been found there together with possibly the oldest known archaeological traces of hominid activity

The Plio-Pleistocene rock succession within the East Rudolf sedimentary basin contains several prominent felsic volcanic tuffs The more extensive of these tuff horizons are vitally important for both stratigraphical subdivision and relationships[20], and the dating of fossil faunas within the sequence At an early stage of the exploratory work at East Rudolf we were able to obtain a date of 2 61 ±0 26 Myr for the important KBS tuff horizon[7], using argon-40/argon-39 age spectrum analysis of a collection of large fresh sanidine crystals which had been separated from KBS pumice cobbles in the field Dating of the other tuff horizons was, however, more difficult

Certain depositional and other characteristics of the East Rudolf tuffs suggest that the base of each major tuff horizon can be regarded as an isochronous surface within rather narrow limits Thus, by mapping dated tuffs and their lateral equivalents and considering information from the geomagnetic reversal stratigraphy[22] it should be possible to produce a detailed geochronological map of East Rudolf, from which the age of any faunal or archaeological site can be estimated with close precision

A complex of Miocene–Recent volcanics and sediments borders the East Rudolf Basin on its entire eastern side The complex is cut by the main Pleistocene rift which runs between the Sugata Valley and Lake Stephanie A number of detailed studies within this area will be necessary in order to identify the provenance of the sediments and tuffs in the East Rudolf Basin and to resolve questions about the location of the ancient drainage channels and the character and timing of the source eruptions

There is wide interest in the fossil hominids from East Rudolf, the cranium KNM-ER 1470 has attracted particular attention It is, therefore, appropriate to discuss summarily the main conclusion of our 1970–1973 dating programme, although full publication of the results of these and other projects must await the completion of the field mapping

Over one hundred rock and mineral samples from East Rudolf have been analysed by a combination of either conventional K–Ar, total degassing and spectrum ^{40}Ar/^{39}Ar age or fission track dating methods[29-35] Figure 1 summarises our present conclusions regarding the East Rudolf time sequence, and illustrates the relationship between the dated tuffs and the world wide geomagnetic polarity reversal time scale The relationship of hominid fossil sites to the dated tuffs has been summarised by Brock and Isaac[22]

Dating work on a sanidine concentrate from a single pumic lump taken from the Chari Tuff, at Ileret (Fig 1)

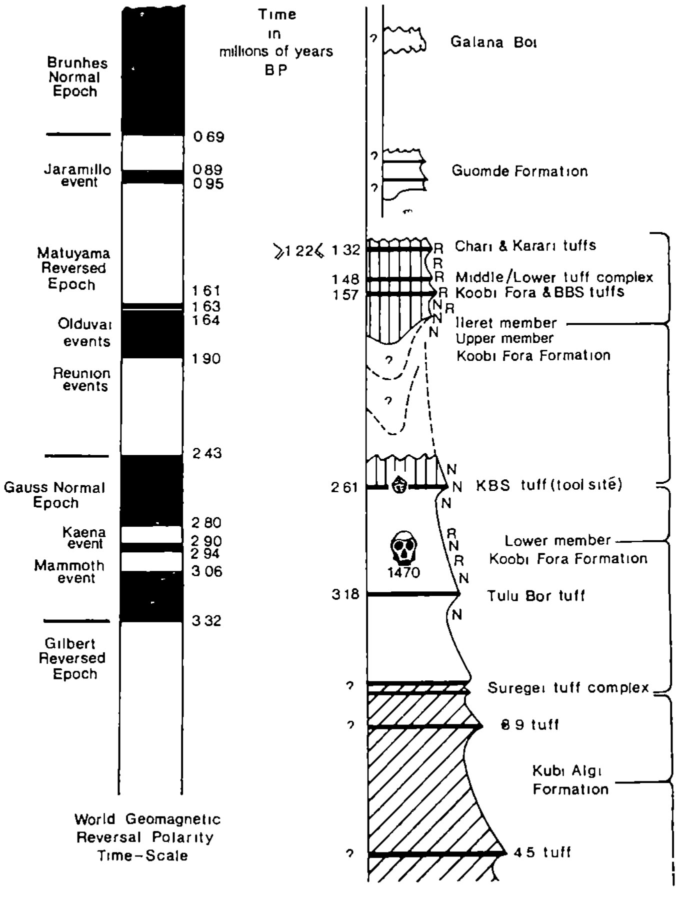

Fig 1 Dated tuffs in the East Rudolf sedimentary basin Palaeomagnetic data from Brock and Isaac[22] and stratigraphical nomenclatuure from Bowen and Vondra[20]

suggested minimum apparent ages of 1 2 Myr from total degassing analysis, and 1 28±0 23 Myr from age spectrum analysis Age spectrum analysis of another sanidine concentrate revealed minor Ar loss and excess Ar contamination effects, and indicated a minimum apparent age of 1 22±0 01 Myr for the major juvenile sanidine component

An apparent age of 1 48±0 17 Myr was obtained by total degassing analysis of sanidine concentrates from pumice taken from the Lower–Middle Tuff Complex, at Ileret (Fig 1)

Apparent ages obtained by total degassing analysis from seven independent sanidine concentrates from the Karari Tuff (Fig 1) ranged from 0 6 to 1 39 Myr Age spectrum analysis revealed that both argon loss and excess argon errors are present in these concentrates A close maximum apparent age of 1 32±0 10 Myr was obtained for the juvenile sanidine component by age spectrum analysis

During age measurements of the Koobi Fora Tuff (Fig 1) it was difficult to avoid the effects of partial and complete overprinting by later events, and the effect of contamination by xenolithic and/or detrital material Imprecise age spectrum results at first suggested an apparent age of 1 1± 1 7 Myr, whereas total degassing apparent ages, obtained from a large number of independent samples, ranged from 1 53 to 1 69 Myr Further age spectrum studies indicated Ar loss and excess Ar errors, a minimum apparent age of 1 48±0 23 Myr, and a close apparent age of 1 57±0 00 Myr for the major juvenile sanidine component Evidence of severe overprinting at around 1 0 Myr was also obtained

Apparent ages ranging from 0 87 to 1 66 Myr were obtained from the BBS Tuff Complex (Fig 1) by total degassing analysis of seven independent sanidine concentrates from pumice Age spectrum analysis revealed both Ar loss and contamination errors The two principal feldspar components in the sample analysed using this method, have apparent ages of 1 70±0 04 Myr and 1 56±0 02 Myr, respectively

A considerable amount of dating work has been done on samples from the KBS tuff (Fig 1) Although the sanidine component in this tuff has certainly been subjected to a number of partial or complete overprinting events, severe contamination or excess argon effects have not been identified Total degassing apparent ages from ten independent sanidine concentrates range between 0 52 and 2 64 Myr Seven age spectrum analyses of further, independent KBS sanidine concentrates identified two age components crystallisation at an apparent age of 2 61± 0 26 Myr with a minimum apparent age of 2 54±0 53 Myr, and overprinting by later events at about 2 42±0 02 Myr, 2 01±0 03 Myr, 1 75 Myr and 1 0 Myr (all apparent ages)

Age spectrum analysis of a sanidine concentrate from Tulu Bor pumice (Fig 1) revealed it to be a mixture of accessory sanidine with an apparent age of 4 0±0 01 Myr, and juvenile sanidine with an apparent age of 3 18±0 09 Myr

Two tuffs in the Kubi Algi Formation (Fig 1) were examined using a number of dating methods So far, however, only very imprecise indications of apparent age have been obtained These are about 3 9 and 4 5 Myr, respectively

Plio-Pleistocene plateau basalts capping the volcanic terrain north-east of the sedimentary basin have an average K–Ar minimum apparent age of 2 20±0 04 Myr The Kokoi basalts occurring within the basin have been dated using K–Ar methods, at an average apparent age of 3 62±0 36 Myr Similar basalts entering the basin from the south-east near Kubi Algi have average apparent K–Ar ages of 3 8±0 4 Myr and 3 80±0 38 Myr

Miocene peralkaline rhyolites at Kubi Algi have average K–Ar apparent ages of 7 5±0 8 Myr An obsidian from Shin has been dated using the K–Ar method, at an apparent age of 11 8±0 9 Myr A variety of basalts exposed in the area of the Suregei Cuesta have average K–Ar apparent ages between 11 6±0 5 Myr and 14 1±1 4 Myr Several extensive eutaxitic felsic ignimbrites found in the Ethiopia–Kenya border area, near Gum Dura, have average K–Ar apparent ages near to 16 15±0 12 Myr The oldest basalts which have been dated, have average K–Ar apparent ages around 17 3±1 11 Myr, and outcrop in the Buluk Gap and near Fora water hole

This dating work on rocks from the East Rudolf Basin, completed in 1973, confirms the suggested age of 2 61±0 26 Myr reported for the KBS tuff in 1970 (ref 7), and places it securely within a chronologically satisfactory sequence of dated tuffs Our conclusions are compatible with palaeomagnetic polarity reversal results from sediments and tuffs in the basin[22] The compatibility of independent evidence is a very strong argument for accepting the chronology now proposed for East Rudolf A discrepancy between this chronology and the middle part of that proposed by Brown and Lajoie[36] for the Shungara Formation of the Omo Valley of southern Ethiopia is suggested by detailed faunal correlation between the two areas[37] This is under joint investigation Important episodes of hydrothermal overprinting affected the rocks of the East Rudolf Basin between 2 05 Myr and 1 75 Myr age and again at about 1 1 Myr and 0 5 Myr age We believe that these overprints have been caused by thermal activity related to magmatic doming, major rift movements and concomitant volcanism It is significant that the three major rift faulting events in Kenya and Tanzania have been dated at 2 1 Myr, 1 2 Myr and near to 0 4 Myr, respectively[38]

This work has received support and encouragement from R E F Leakey, G Ll Isaac, K Kimeu, members and field assistants of the East Rudolf Research Project, the National Museums of Kenya, the Royal Society, the Natural Environment Research Council, and the Universities of London and Cambridge

Probing broad lines in molecular spectra by optical site selection spectroscopy

WE report evidence that suggests that narrow-line spectra can be obtained for many organic compounds without the difficulties commonly found with traditional mixed-crystal line-narrowing techniques Furthermore, our findings suggest a new method by which low temperature line-broadening mechanisms may be studied

Even at very low temperatures the optical absorption and fluorescence bandwidths of many organic compounds in solution remain very broad, typically several hundred cm^{-1}, with unresolved or poorly resolved structure The techniques of mixed crystal spectroscopy[1,2] and its more recent variant due to Shpol'skii[3] have been developed to probe whatever structure may be hidden in these broad lines or bands (The spectra of neat crystals often yield sharp lines at helium temperatures but these spectra are often more representative of collective excitations or excitons and not the 'unperturbed' molecular spectrum) Unfortunately, narrow-line mixed-crystal and Shpol'skii spectra can be obtained only in those special instances in which a suitable host crystal or quasi-crystal can be made to fit the subject molecule The purpose of the host is to hold every subject molecule in the sample in one or another of a small number of available environments (crystal fields) For most organic compounds suitable hosts are not known

The method for obtaining narrow-line spectra which we describe here was first demonstrated by Szabo[4], in a study of ruby We conclude from studies of a variety of organic compounds that the method is indeed useful in obtaining high resolution spectra of organic molecules in low temperature solutions It seems to be much more flexible than the mixed-crystal and Shpol'skii methods because is discards the very special host matrices on which those techniques are based and can be used with a variety of hosts including glasses and polymers

It seems probable that the vibronic lines of two identical molecules in a frozen amorphous host solution are shifted with respect to each other if and when their local environments differ, and that in many host media the shift may far exceed the widths of the individual vibronic lines Furthermore, it is a natural assumption that a molecule interacts optically only with light that is resonant with one of its vibronic lines

If these assertions are approximately true, then it should be possible to do 'mixed-crystal' spectroscopy in arbitrary vitreous hosts simply by using optical probes that are spectrally very narrow, because the light itself will pick out only those subject molecules that happen to be in identical local environments or sites in the host For convenience we will term this technique 'optical site selection spectroscopy'

We have observed, from a variety of organic compounds, narrow-line fluorescence similar to that reported by Personov *et al*, for perylene[5] In every case we used spectrally narrow ($\Delta\nu/c$<0 2 cm^{-1}) laser excitation An example of our results is shown in Fig 1 When naphthacene in a frozen vitreous solvent is excited by a conventional $\Delta\nu/c$ ~ 1,000 cm^{-1}) source, the result is the normal emission spectrum (Fig 1*a*) The vibrational bands, although well resolved, are broad, about 230 cm^{-1} for the 0 0 band Excited in its 0 0 band at 4,765 Å by an argon ion laser, however, naphthacene exhibits the strikingly different spectrum (Fig 1*b*) The emission line that occurs at about 4,830 Å is 3 cm^{-1} wide The various sharp lines in Fig 1*b* are allowed transitions from the lowest level of the excited state to the vibrational levels of the ground state The broad band accompanying each line can be interpreted as the analogue of the phonon sidebands often observed in mixed-crystal spectra[6] As a check, a vibrational analysis of the spectrum in Fig 1*b* was carried out The ground state vibrational frequencies thus obtained are in excellent agreement with those obtained for naphthacene by different methods[7]

According to these results it seems natural to conclude that, at low temperatures under broadband excitation, naphthacene exhibits an inhomogeneously broadened

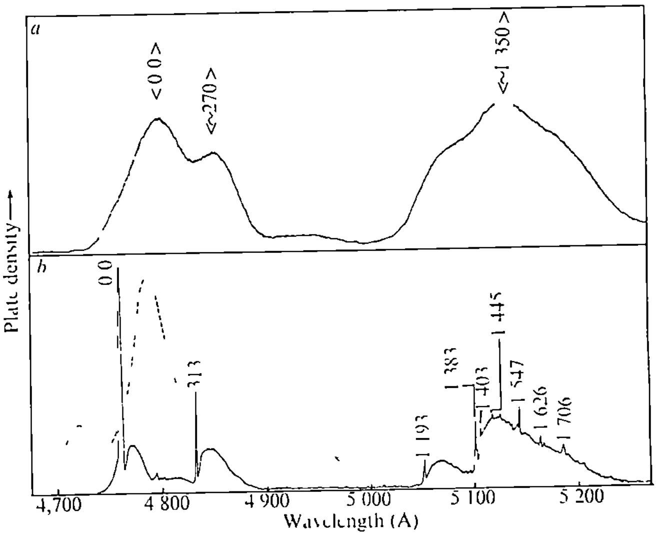

Fig 1 The fluorescence spectrum of a 10^{-4} M solution of naphthacene in a 2-methyltetrahydrofuran glass at 4 2 K *a*, Excited with broadband (~ 100 Å) Hg line at 4,358 Å, *b*, excited with 4,765 Å argon ion laser line (bandwidth < 0 2 cm^{-1}) Dotted curve is a portion of the absorption spectrum of naphthacene at 4 2 K The 0 0 bands are taken as the origins The distances to succeeding peaks are given in cm^{-1}

spectrum, one that is simply the superposition of many sharp spectra such as the spectrum in Fig 1*b* There is thus no intrinsic importance in either the width or the absolute location of the peaks in Fig 1*a*, since they merely reflect the wide variety of environments provided for naphthacene by the particular vitreous host used For this reason we have used brackets ⟨ ⟩ to signify an average value in labelling the principal peak in Fig 1*a*

If our interpretation of the origin of low temperature spectra is valid, excitation by very narrow band light in higher frequency absorption bands instead of the 0 0 band could lead to a much greater number of fluorescence lines (which may be resolvable under the appropriate conditions)

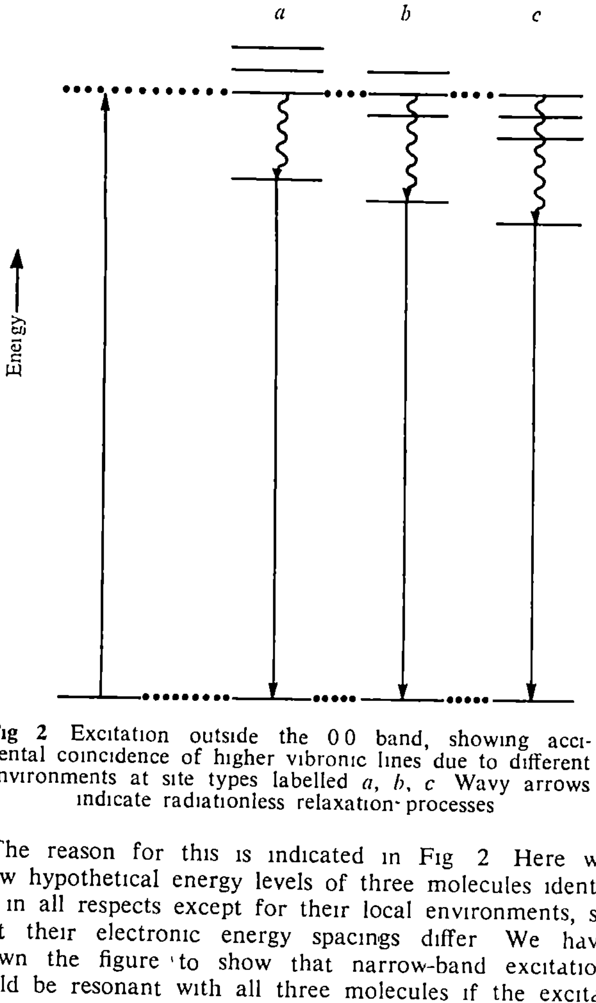

Fig 2 Excitation outside the 0 0 band, showing accidental coincidence of higher vibronic lines due to different environments at site types labelled *a*, *b*, *c* Wavy arrows indicate radiationless relaxation processes

The reason for this is indicated in Fig 2 Here we show hypothetical energy levels of three molecules identical in all respects except for their local environments, so that their electronic energy spacings differ We have drawn the figure to show that narrow-band excitation could be resonant with all three molecules if the excitation were at the frequency shown That is, excitation higher than the 0 0 band may lead to accidental coincidences and cause the fluorescence spectrum to be characteristic of several or many (in this example, three) environments at once

Phenanthrene in methylcyclohexane typifies the multiple-line phenomenon In Fig 3 we show the result of very narrow-band excitation of phenanthrene at 3,250 Å, about 0 24 eV (220 Å) above the centre of the ⟨0 0⟩ absorption band The spectrum does contain narrow lines, and they are more numerous than previously observed in mixed-crystal fluorescence spectra of phenanthrene[3] The increased background is probably due to a superposition of the 'phonon' bands associated with all of the extra lines

Studies of substituent effects on narrow-line spectra were also carried out for derivatives of two organic compounds, naphthacene and anthracene In two parent aromatic hydrocarbons and four derivatives the spectra ranged from very broad and unresolved to very narrow lines In particular, the broadening effect of phenyl groups, often observed at room temperature, remains substantial at 4 K even with laser excitation Methyl groups were also found to broaden the spectra, whereas halogen substitution had no apparent effect

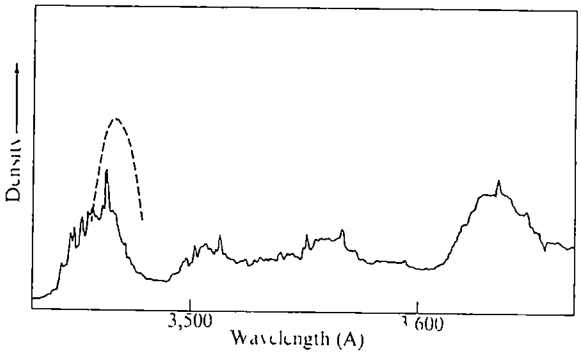

Fig 3 The fluorescence spectrum of a 10^{-4} M solution of phenanthrene in methylcyclohexane glass at 4 2 K Excitation is at 3,250 Å with a He–Cd ion laser The excitation is 0 24 eV (220 Å) above the ⟨0 0⟩ band The dotted curve is a portion of the ⟨0 0⟩ absorption band of phenanthrene in methylcyclohexane glass at 4 2 K

We also examined a number of organic dyes Although only broadband emission was obtained from ionic dyes, a few narrow lines were observed in a merocyanine

We have also studied solvent effects in the production of narrow line spectra, including the effects of solvent polarity Such compounds as naphthacene are only slightly sensitive to the polarity of the host solvent The linewidth of the 313 cm^{-1} naphthacene fluorescence line is about 3 cm^{-1} in nonpolar methylcyclohexane, and about 5 cm^{-1} in the polar mixture of ethanol and methanol (1 1) Personov indicated a similar weak effect for perylene[5] In azulene, which changes its dipole moment by 1 1 debye on excitation[9], polar solvent broadening is, however, severe

In summary, optical site selection in low temperature glasses provides a straightforward technique for observing vibronic structure normally obscured by inhomogeneous broadening Typical inhomogeneous linewidths in these experiments are on the order of several hundred cm^{-1} The homogeneously broadened 'zero-phonon' lines observed are about 3–10 cm^{-1} wide Their measurement may prove to be a sensitive probe of the local solvent environment To the extent that a low temperature glass represents a liquid solution at a fixed instant in time, studies of this nature may also provide insights into broadening mechanisms in liquid solutions

We have begun a detailed examination of some of these effects using tunable laser excitation

We thank K H Drexhage for helpful discussions The work of two of us, J H E and W C M, was partially supported by a grant from the United States Air Force Office of Scientific Research

The origin of the far-infrared polarisation of liquid water

LIQUID water has a strong far-infrared polarisation The origin of this has rarely been discussed in detail, although it causes the difference between the optical permittivity of about 1 8, and the limiting high frequency microwave (ε_∞) permittivity of about 4 2 The phenomenon has been attributed by Zafar *et al*[1] to a high frequency relaxation of amplitude 2 4 in the permittivity, and a relaxation time of ~50 ns resulting from the orientation of water molecules that are free of hydrogen bonds Unfortunately, the authors did not apply Sherlock Holmes'[2] adage that when you have eliminated the impossible, whatever remains, however improbable, must be the truth Not all possible explanations of this polarisation have been considered and eliminated, although the correct one has been mentioned There can be little doubt that there is, at present, no evidence for a new orientational relaxation

Another possible cause of the polarisation is, of course, resonance absorption, discussed briefly by Zafar *et al*[1] in terms of a single damped resonance absorption centred at 170 cm^{-1} It may not be possible to describe, however, a resonance absorption band using a single damped resonator, there may be a continuous distribution of resonators, and any arbitrary distribution of intensity may occur, even one that mimics a relaxation absorption Relaxation and broad resonance absorptions cannot be distinguished by direct measurement, and so, to decide which is occurring in liquid water, the spectrum of water can be compared with that of ice, which has no relaxation absorption in this frequency region

Ice I has an infrared polarisation responsible for the difference between the optical and microwave dielectric constants 1 8 and 3 1, respectively[3] The difference, Δn, between the corresponding refractive indices is proportional to the negative second moment of the absorption spectrum

$$\Delta n = \tfrac{1}{2}\pi^{-2} \int_{\text{band}} K(\nu)\, \nu^{-2} d\nu$$

where $K(\nu)$ is the absorptivity at wave number ν In ice, the main contributory bands are the H_2O internal motions in the range 3,600–1,000 cm^{-1}, the H_2O rotational vibrations centred in the infrared at 850 cm^{-1}, and the H_2O translational vibrations centred at 229 cm^{-1} They contribute, respectively 0 0506, 0 0728 and 0 347 to the infrared component of the low frequency refractive index[3]

Internal motions contribute little in ice, they contribute even less in water, because the O–H stretching frequencies are higher They might contribute, say 0 05 to the refractive index The rotational vibrations in ice extend from 525 to 1,040 cm^{-1}, the infrared intensity being centred at ~850 cm^{-1} The effective dipole moment is 1 45 *D* (ref 4), compared with the value for the vapour of 1 84 *D* In the liquid there is a broad band because of these vibrations Its peak is shifted from 850 cm^{-1}, the frequency in ice, to about 650 cm^{-1}, and it is greatly broadened, the lower limit decreasing from 525 cm^{-1} to 300 cm^{-1} or less The negative second moment is, therefore, about twice as great for the liquid as for ice, and so its contribution to the low frequency refractive index is about 0 15 A more accurate value may be obtainable from the measured spectrum, but it would be difficult to separate the overlapping rotational and translational bands with any reasonable certainty

Absorption in ice, which results from the translational vibrations, extends from 318 cm^{-1} to zero frequency[5] and its maximum is at about 229 cm^{-1} The integrated intensity[6] shows that the effective charge for the stretching of the hydrogen bond is about 0 4*e*, where *e* is the electronic charge

The band is broadened and the peak shifted to about 220 cm^{-1} in vitreous ice[7], and undoubtedly persists in the liquid, because the diffusion coefficient, the viscosity, and the relaxation of molecular and nuclear orientational polarisation[8] indicate that a water molecule requires about 10 ps to change its position or orientation at 25° C, whereas a frequency as low as even 30 cm^{-1} corresponds to about 1 vibration ps^{-1} It is no doubt broadened greatly by the increased disorder of the liquid as compared with ice and by the short lifetime of a state In addition, the stretching force constant of the hydrogen bonds undoubtedly takes on a range of values because of the range of hydrogen bonds All of these processes broaden the band and increase its negative second moment Because of the increased length of the hydrogen bond, the force constants are undoubtedly less in water than in ice, and that will cause the whole band to shift to low frequency, and will further increase the second moment The band has not been analysed in detail, but the peak intensity is at about 170 cm^{-1} (see ref 9 and refs quoted there) If the whole ice band were shifted by the ratio 170 229, the negative second moment would be doubled, and the contributions to the low frequency refractive index would be doubled to about 0 7 The discussed broadening would further increase the contribution The increased length of the hydrogen bond might then decrease the effective charge, thus reducing the contribution to the refractive index

It seems likely that the internal rotational and translational resonance absorption contribute somewhat less than about 0 9 to the low frequency refractive index, which corresponds to a value for ε_∞ of somewhat less than about 5, compared with the experimental value of 4 2

It seems, therefore, that there is little or no room for a relaxation absorption, and that if it does occur, it is at least an order of magnitude less than that assumed by Zafar *et al*[1], and is strongly overlapped by resonance absorption

This conclusion is confirmed by the H_2O–D_2O isotope effect in the spectrum If there were a relaxation absorption because of the rotation of molecules, the relaxation times for D_2O and H_2O would have an approximate ratio of 1 4 The relaxation times deduced by Zafar *et al* are in the ratio 0 85 Absorption because of damped translational vibrations, for which corresponding features would be at frequencies and absorptivities in the ratio 1 05, is more consistent with the measurements summarised by Zafar *et al*[1] when allowance is made for the effects of the well established orientational relaxation Both the infrared and Raman spectra of H_2O and D_2O have bands centred at about 170 cm^{-1}, and there is a Raman band at about 60 cm^{-1} (ref 10) These no doubt result from damped translational vibrations, not from rotational motions

DRS HASTED, ZAFAR AND CHAMBERLAIN REPLY Although he has cast us[1] in the role of Inspector Lestrade[2], Dr Whalley[3] performs a useful service by questioning our neglect of resonance absorptions in the discussion of the enhanced permittivity increment, $\varepsilon_\infty - n^2$, of water Complete analysis of the origins of this increment must await the collection and analysis of refractive index data of improved accuracy over a much wider frequency range than has so far been investigated, but in the meantime we point out that the application of the Kramers–Kronig relationship to absorption data alone, can be confusing The integrated negative second moment of the power absorption coefficient contributes proportionally not to ν^{-2} but to ν^{-1}, so that a shift of the absorption band by a factor of 229 170 alters its contribution to n^2, not by 235% but by 83% Further, the maximum of the liquid water band taken to be at 170 cm^{-1} is now placed as high as 200 cm^{-1} (ref 4)

In liquid water, both the 683 cm^{-1} and the 200 cm^{-1} band contribute to the $\Delta\varepsilon'$ increment just as they do in ice They arise from intermolecular librational resonance processes Normal coordinate analysis[4,5] has been used to assign the 683 cm^{-1} band to libration of the symmetry species B_2 of the $(H_2O)_5$ pentamer, and the 200 cm^{-1} band to the translational modes of species A_1, B_1 and B_2 Both processes are resonant rather than relaxational, and exhibit an S-shaped 'anomalous dispersion'[6] in ε' Libration processes also contribute an increment $\varepsilon' \propto \mu^2/I\nu^2$, according to Poley[7] Note that it is to ε' and not to n that there is a contribution proportional to ν^{-2} This type of absorption has been called 'Poley absorption', and is found in many unassociated organic liquids in the submillimetre region (for example ref 8) Apparently, no band corresponding to free molecules is found in water or in alcohols[9], with the exception of t-butyl alcohol, in which there seems to be less association (J C , G J Davies, J B H and M S Z , unpublished data)

We believe that there are only a small proportion of free molecules in liquid water, and that their reorientation is a relaxation rather than a resonance process The extraordinarily large bandwidth does not seem to be strongly temperature dependent, as would be the case for a resonance process, nor is the centre of the band dependent upon I, the molecular moment of inertia

There is, as yet, no evidence to rule out the presence of an underlying continuum such as may be contributed by a relaxation process, although its extent and magnitude may not be as large as would at first seem Certainly, the absence of a second relaxation in ice should not lead us to anticipate its absence in liquid water Resonance processes in the submillimetre band are often accompanied by an actual minimum in the refractive index[10], or in the permittivity function, and Poley absorption may be of this type This phenomenon may also contribute in liquid water in the 1–100 cm^{-1} range Our double Debye analysis neglects such a contribution and leads to a discrepancy in ε_∞ (ref 1, Fig 6) which could perhaps be resolved if it were taken into account

No relaxation isotope effect, $\tau(D_2O)/\tau(H_2O) = 1\ 4$, is to be expected, because the molecular moment of inertia, although involved in resonance rotation, is not involved directly in relaxation theory For example, it does not appear in the water principal relaxation as interpreted on the Debye–Stokes theory[11] The probable error on both proposed second relaxation times is very large, and the ratio could lie anywhere between 0 5 and 1 5

We do not wish to imply that the resonance processes can be neglected in comparison with the relaxation of free molecules, as could have been concluded from our ambitious attempt to construct a Cole–Cole diagram between ε_∞ and n_D^2 Rather, the increment must be a summation

$$\varepsilon_\infty - n_D^2 = \Delta\varepsilon'(\text{libration}) + \Delta\varepsilon'(\text{translation}) + \Delta\varepsilon'(\text{relaxation})$$

Black polar bears

WHITE coloration of many animals in cold environments decreases the possibility of visual detection because of the lack of contrast between the animal and its white background White hair thus provides concealing coloration for prey species such as arctic hare (*Lepus arcticus*), and for predators such as the polar bear (*Ursus maritimus*) and arctic fox (*Alopex lagopus*)

Such animals often live in areas where aerial detection is feasible because of the lack of overhead cover, yet present remote sensing techniques do not usually distinguish these white animals against a white background Thermal infrared imagery will detect some white animals, including the polar bear[1] and white-coated pups of the grey seal (*Halichoerus grypus*) (N A Ø , and D M L , unpublished) but only in certain weather conditions

When cold and windy, sufficient temperature differences may not exist between a well insulated animal and its environment to enable detection by a thermal scanner

Our preliminary attempts to improve detection of white animals on snow suggested that photography in the near ultraviolet band (300–400 nm) of the electromagnetic spectrum markedly increased contrast between some white animals and their backgrounds[2]

We recently obtained oblique photographs of polar bears on the tundra south of Churchill, Manitoba, Canada The low visual contrast of a polar bear on snow is shown by black and white photography in the visible region of the electromagnetic spectrum (Fig 1*a*) Ultraviolet photography, however, resulted in a black image of the polar bear against white snow (Fig 1*b*)

This difference in the ultraviolet absorbance and reflectance characteristics of the polar bear pelt and snow has direct applications for remote sensing of polar bears in the field Although the distance between polar bears on the tundra makes photographic surveys impractical over wide areas of the arctic, ultraviolet photography may be useful for aerial detection and censusing bears in specific areas, where they congregate at certain times of the year, or along known migration routes The ultraviolet band may also be used in long range detection and observation of bears on ice At present, such observations, often made by telescope, are also hindered by the lack of contrast between the bear and its environment Contrast may be enhanced by coupling an ultraviolet transmitting lens covered by a visibly opaque, ultraviolet transmitting filter, with an image intensifier whose spectral sensitivity extends into the near ultraviolet region of the electromagnetic spectrum

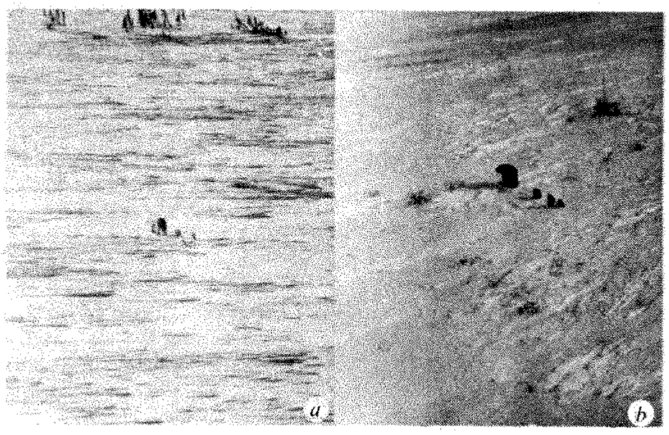

Fig. 1 Photography of a polar bear (*Ursus maritimus*) and three cubs on tundra. *a*, Normal black and white photograph in the visible portion of the electromagnetic spectrum (Kodak Double-X Aerographic 2405 film, Hasselblad 150 mm Sonnar lens, f/16, 1/500 s). *b*, Ultraviolet photograph (Kodak Aerographic Double-X 2405 film, Hasselblad 105 mm UV-Sonnar lens, Kodak 18A filter, f/5.6, 1/500 s).

This observation of 'black' polar bears seems to have further implications. At present, the biological significance of white coat coloration in animals is not clear. Whiteness in arctic climates obviously provides camouflage for many birds and mammals. Theoretical analysis and quantitative measurements suggest that some white pelts transfer solar energy more efficiently to the skin than dark pelts[3,4]. Thus white coloration may also play an important role in thermoregulation for a number of species including the white-coated pups of the harp seal (*Pagophilus groenlandicus*)[5]. The older view that dark pelts absorb solar radiation while white pelts reflect it and thus reduce radiation absorption[6] is probably incorrect. Regardless, the fact that some white pelts absorb ultraviolet radiation while others, such as the arctic hare reflect it[2], suggests that any discussion of "life's color code"[6] is incomplete without further consideration of the near ultraviolet component in solar radiation.

Metabolic hydroxylation of a chlorobiphenyl containing only isolated unsubstituted positions—2,2′,4,4′,5,5′-hexachlorobiphenyl

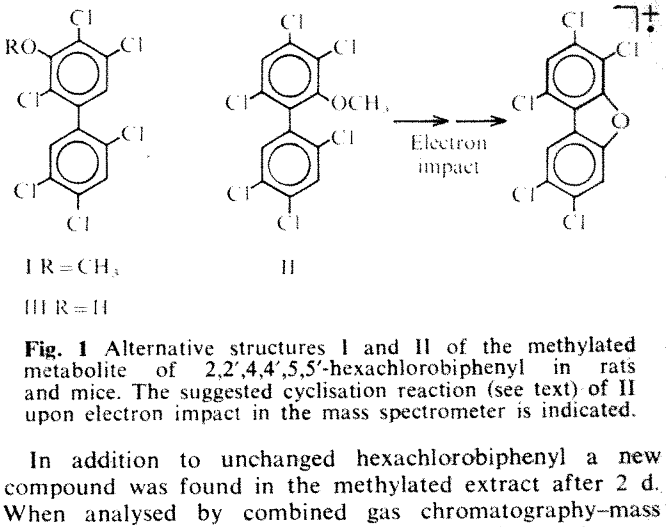
RECENT investigations on the metabolism of chlorobiphenyls of known structure have shown that compounds containing four chlorine atoms or less are hydroxylated by rats, rabbits and pigeons[1–5]. All the compounds investigated have two unsubstituted carbon atoms in ortho positions to each other. It has been suggested that this substitution pattern is required for the metabolic breakdown of chlorobiphenyls[6]. A thorough investigation of the chlorobiphenyl residues found in man and in higher animals partly confirms this suggestion[7].

Hutzinger *et al.*[2] have investigated the fate of a chlorobiphenyl containing only isolated, unsubstituted carbon atoms—2,2′,4,4′,5,5′-hexachlorobiphenyl—in rats, pigeons and trout. No hydroxy-containing metabolites were detected in the excreta by the methods used. This chlorobiphenyl is one of the major components in technical PCB with chlorine contents above 50%. Furthermore, it is found in relatively high amounts in all species investigated including man[7].

It has been shown, however, that rabbits given 1,2,3-, 1,2,4- or 1,3,5-trichlorobenzene always excreted chlorinated monophenols. The yields over 5 d were 78, 42 and 5%, respectively[8].

The fact that even 1,3,5-trichlorobenzene (containing only isolated unsubstituted carbon atoms) is hydroxylated, led us to reinvestigate the behaviour of 2,2′,4,4′,5,5′-hexachlorobiphenyl in some animal species.

Rats were given the chlorobiphenyl[9] in peanut oil (20 mg ml^{-1}) and an amount corresponding to about 15 mg was consumed during the night by each animal. Faeces were collected daily, dried and extracted with ether (Soxhlet extraction), The extracts were divided into two parts, one of which was treated with diazomethane. After evaporation of solvent the residue was dissolved in hexane and shaken with sulphuric acid before analysis by gas chromatography using an electron capture detector[7]. The acid treatment removes most unwanted extractives but does not affect chlorobiphenyls and methoxy-chlorobiphenyls.



I R=CH$_3$ II

III R=H

Fig. 1 Alternative structures I and II of the methylated metabolite of 2,2′,4,4′,5,5′-hexachlorobiphenyl in rats and mice. The suggested cyclisation reaction (see text) of II upon electron impact in the mass spectrometer is indicated.

In addition to unchanged hexachlorobiphenyl a new compound was found in the methylated extract after 2 d. When analysed by combined gas chromatography–mass spectrometry (quadropole instrument) this substance showed a molecular ion at 388 mass units (m.u.) (6 Cl) corresponding to a methoxyhexachlorobiphenyl. The structure of this compound (Fig. 1), obviously derived from a phenolic metabolite of 2,2′,4,4′,5,5′-hexachlorobiphenyl, must be I or II provided no migrations of chlorine atoms have taken place.

Mass spectral studies performed in this laboratory using about 35 synthetic methoxychlorobiphenyls (S. J. and G. S., unpublished) have shown that compounds containing a methoxy group in the two position, II, for example, readily lose CH$_3$Cl (50 m.u.) upon electron impact. This results in very abundant peaks in the range 83–234% of the molecular ion at M$^+$-50 m.u. which can be explained by the formation of cyclic structures (Fig. 1).

Similar fragmentation patterns have previously been

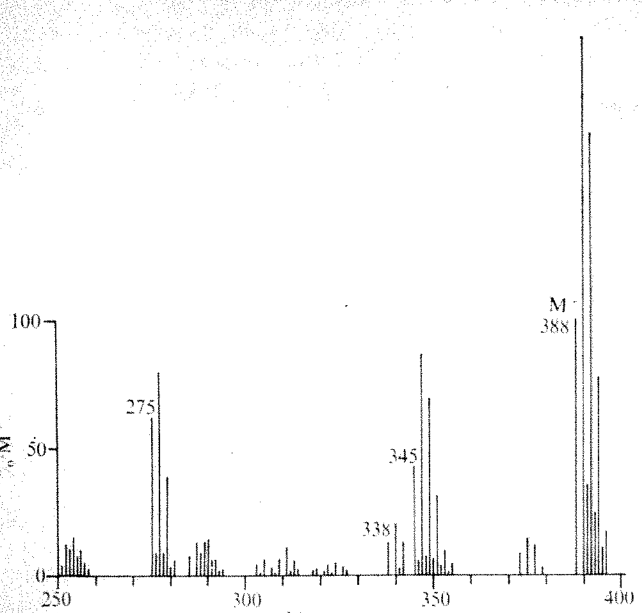


Fig. 2 Part of the mass spectrum of the methylated metabolite.

observed in the mass spectra of 2-methoxychlorodiphenyl ethers[10,11].

The loss of CH_3Cl in the mass spectra of all 3- or 4-methoxychlorobiphenyls investigated so far have on the other hand, never exceeded 30% of the molecular ion. The mass spectrum of the methyl ether of the present metabolite (Fig. 2) shows a peak at M^+-50 m.u. which is only 13% of the molecular ion. This fragmentation strongly favours structure III of the original phenol. Final proof for the structure, however, must await comparison with synthetic material of known structure.

The elimination rate of unchanged hexachlorobiphenyl and the metabolite (assuming equal detector response on GLC) is shown in Fig. 3. The total amount of metabolite excreted during 7 d was calculated to be about 1.3% of the dose. The corresponding figure for unchanged biphenyl was about 7%. No trace of III or conjugates thereof were found in the urine.

Our experiments do not discriminate between microsomal or microbial hydroxylation of the chlorobiphenyl as no bile cannulation experiments have been performed. But the presence of the metabolite in the faeces—and not in the urine—is in accordance with the results of other investigations concerning the metabolism of PCB in rats[3,4].

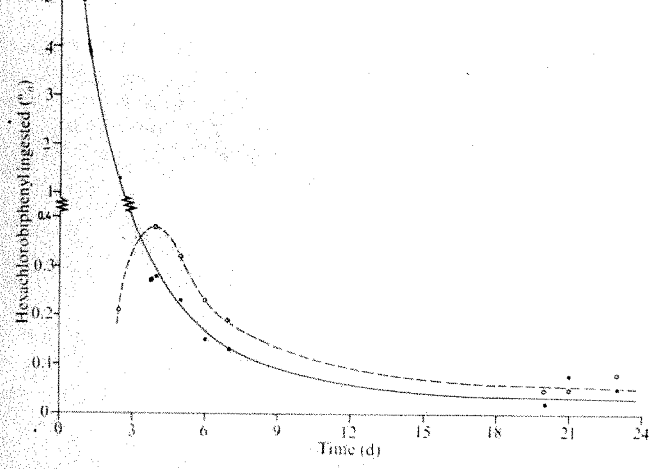

Fig. 3 Excretion rate (faeces) of 2,2′,4,4′,5,5′-hexachlorobiphenyl (———) and its metabolite (– – – –) from a rat as % hexachlorobiphenyl ingested.

Control experiments showed that bacterial action during the drying of the faeces was not responsible for the hydroxylation.

Mice given the hexachlorobiphenyl also excreted III (GLC) in the faeces. When the substance was given to quails (about 11 mg per animal) no metabolite could be detected in the excreta. It was, however, found that large amounts of unchanged chlorobiphenyl were excreted in both faeces and eggs—about 9 and 33%, respectively, during 10 d.

The results presented here show that a chlorobiphenyl containing only isolated unsubstituted positions can be metabolised by mammals albeit at a lower rate than chlorobiphenyls containing vicinal hydrogen atoms. It seems, therefore, that most of the high chlorinated compounds in PCB can be excreted not only unchanged but also as metabolites. The latter route implies that the chlorobiphenyls are not further circulated in the environment but that new compounds are released the persistence and toxicity of which are not sufficiently known.

This work was supported by the National Swedish Environment Protection Board. We thank Drs J. Kihlström and J. Öhrborg supplying the excreta from the mice and Dr C. A. Wachtmeister for discussions. Mass spectra were run by Dr B. Jansson.

Sexual maturation of Japanese eel and production of eel larvae in the aquarium

THE life history of the eel is complex and despite many investigations little is known about its embryonic development. Some investigators such as Grassi and Calandriccio (1896: cited in ref. 1) and Fish[1], described the supposed early development of eels, using developing eggs collected by a trawl for young fish in suspected spawning grounds of eels. The time of fertilisation of these eggs, however, was unknown, and the species involved was uncertain. Artificial maturation of eels by hormonal treatment is another approach which has been attempted by many workers[2–6]. They all, however, failed to obtain mature eggs and sperm and thus to clarify the embryonic development of eels. Here we describe the first success with this approach.

Table 1 Early development of Japanese eel at 23° C

Time after fertilisation	Stage	Remarks
20—50 min	Single cell	Pelagic, with appearance of perivitelline space; egg diameter was 1.3 mm.
80 min—3⅓ h	Cleavage	Typical discoidal cleavage.
3¼—5½ h	Morula	Three to five layers of blastomeres.
5¼— 9 h	Blastula	Blastocoel discernible from outside.
9½—12 h	Gastrula	Blastoderm covering ¼ of yolk.
13—18 h	Embryonic body formation	Blastoderm covering ⅓ to ⅔ of yolk.
19—24 h	Blastopore closure	Differentiation of head and 3 to 12 somites.
25—27 h	Eye vesicle and ear vesicle formation	Tail bud formation.
28—33 h	Heart formation	About 32 somites.
35—37 h	Start of heart pulsation	Embryo covering entire yolk.
38—45 h	Hatching	Membranous fin well developed; no pectoral fins visible.

Silver eels of *Anguilla japonica* were caught in the Mabuchi and Hiranuma rivers in Aomori prefecture (Japan) during September 1973. They were transferred to Hakodate and raised in circulating purified seawater tanks with a capacity of 5.5 gallons. Male eels were injected with Synahorin, a mixture of pituitary gonadotrophin and chorionic gonadotrophin (Teikoku Zoki), and the females were injected with saline suspension of chum salmon pituitary as previously reported[7,8]. More than 20 males and five females became fully sexually mature following these treatments. Eggs and milt were stripped from the fish into glass dishes; fertilisation occurred, and the development of the eggs in normal seawater at 23° C was observed. The spherical ripe eggs (Fig. 1) were white and transparent; they measured about 1.0 mm in diameter. The development of the eel egg is summarised in Table 1.

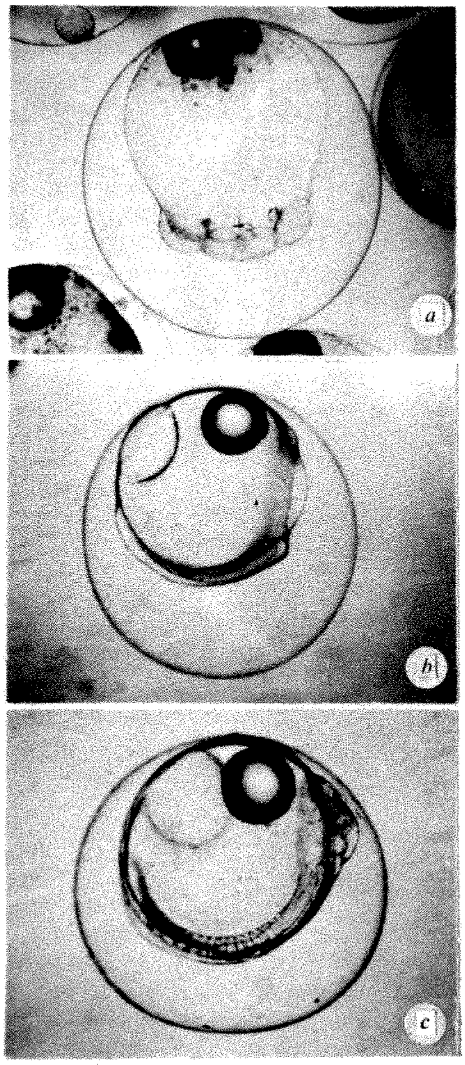

Fig. 1 Living eggs at, *a*, eight-cellstage, × 30; *b*, closing-blastopore stage, × 30; *c*, stage of eye vesicle formation, × 30.

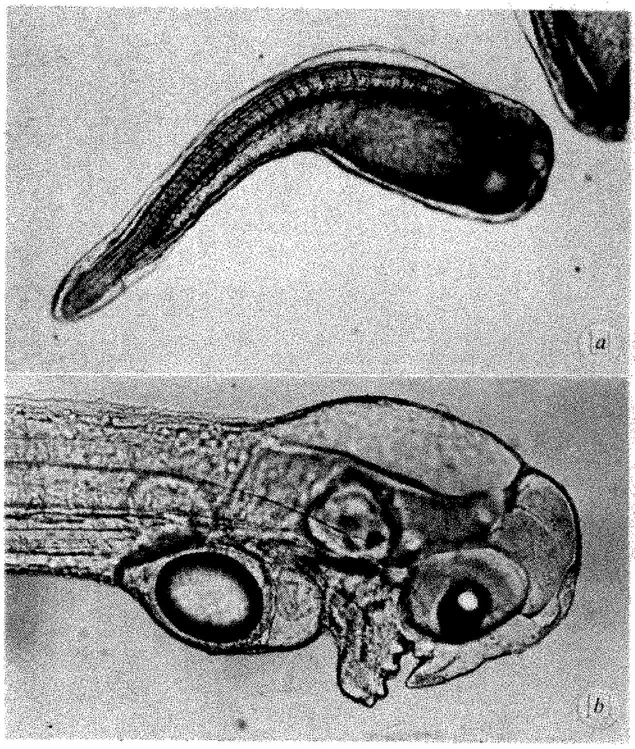

Fig. 2 Living larvae: *a*, 30 min after hatching, × 28; *b*, head of larvae, fifth day after hatching, × 70.

Hatched larvae (Fig. 2) survived for about 5 d. They measured about 4.8 mm, 5.3 mm, 5.9 mm and 6.2 mm in body length on the second, third, fourth and fifth days after hatching, respectively. By the sixth day, when the yolk sac of larvae was almost absorbed, most larvae showed curvature of the tail and then died. Some surviving larvae measured about 5.8 mm in average length. By the third day after hatching, the mouth and anus of the larvae were open, and the pectoral fins also appeared. The brain differentiated into fore, mid and afterbrain, showing a large fourth ventricle. From the fifth to sixth day, the jaw of the larvae developed conspicuously and tooth anlagen characteristic of muraenoid larvae appeared. Fifty-three pre-anal and about 48 postanal myomeres were counted in the sixth day larvae.

These observations allow us to correct and complete earlier claims.

A long continuous pollen sequence from north-eastern Australia

FEW pollen diagrams from Australian Quaternary deposits have been published and none of these extends beyond 10,000 BP. In north-eastern Australia, Lake Euramoo[1] provides a pollen record from 9,700 BP to 1,500 BP and Quincan Crater[2] gives evidence of vegetation changes from 7,250 BP to the present day. Here I outline results from a third site on the Atherton Tableland, Lynch's Crater, which provides a much longer vegetation record.

Lynch's Crater is of volcanic origin, about 600 m in diameter and filled with organic lake and swamp deposits to 45 m below the crater rim. The crater wall has been breached and further swamp development is thereby prevented. In comparison with previously described sites (Fig. 1), Lynch's Crater receives a much higher mean annual rainfall (approximately 2,500 mm), though the crater is at a similar altitude (760 m) and is also located within the basalt-covered Tableland. Under undisturbed conditions, Lynch's Crater was surrounded by Complex Mesophyll Vine forest (terminology from ref. 3), whereas within the area as a whole, rain forest occurs on all well-drained soils with a mean annual rainfall greater than 1,400–1,500 mm. Under lower rainfalls and on soils with impeded drainage, sclerophyll vegetation, normally dominated by species of *Eucalyptus*, or *Melaleuca*, replaces rain forest.

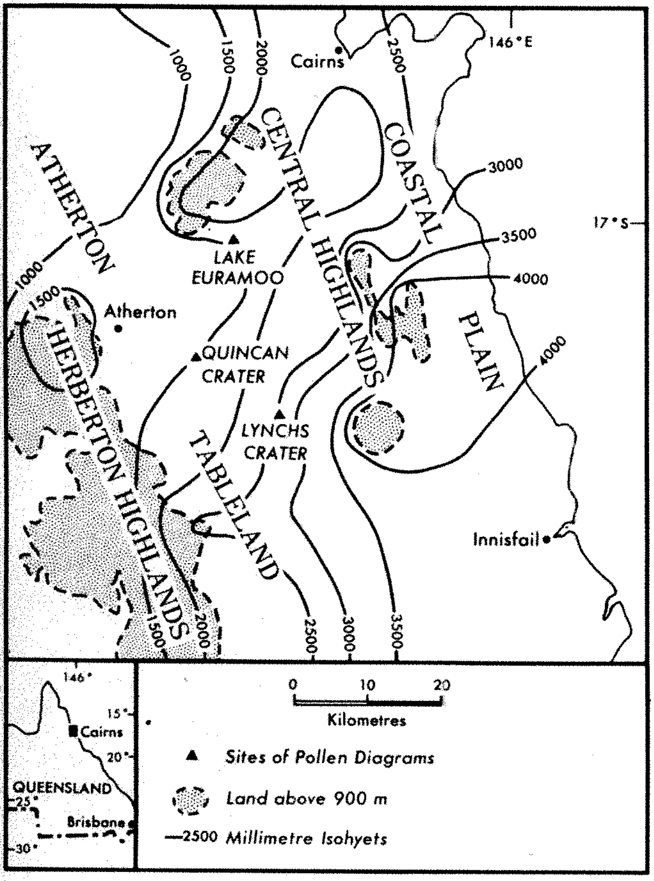

Fig. 1 Location of Lynch's Crater.

A core taken near the centre of the swamp provided 20 m of organic sediments for pollen analysis and radiocarbon dating. Selected results of pollen analyses at intervals along the core are shown in diagrammatic form on Fig. 2. Three distinct periods can be recognised. Zones F, E and D contain high percentages of the rain forest gymnosperms, *Podocarpus* and *Araucaria* and, except for zone E, low values of rain forest angiosperms; zone B is dominated by the sclerophyll taxa *Casuarina* and *Eucalyptus* comp.; zone A is mainly composed of rain forest angiosperm pollen. Zone C is transitional between earlier rain forest and later sclerophyll assemblages. The total number of dry land taxa recorded in each sample is highest in zones E and A and lowest in zone B.

Much of the pollen sequence is beyond radiocarbon dating range. It is difficult to extrapolate the age of the sediment to the base of the core because of variations in sediment type and probably in sedimentation rates, but it may lie between 60,000 and 70,000 years BP. It is suspected that the youngest date (6,850 ± 90 b.p. ANU-958), which corresponds with the zone A/B boundary, may not be accurate, since it could be contaminated by roots younger than the pollen analysed matrix.

Interpretation of the pollen diagram relies heavily on comparisons of the fossil spectra with spectra from surface samples collected within a variety of rain forest and sclerophyll vegetation types in north-east and south-east Queensland[4].

Pollen spectra of zone F correspond with moist araucarian forests (Low Microphyll Vine forests with *Araucaria*) which are extensive in southern Queensland but hardly present in the north-east of the state today. *Araucaria* is a common emergent above subtropical rain forest canopies on basaltic soils where the mean annual rainfall lies between 900 and 1,400 mm (L. J. Webb, communicated at Symposium on Ecological Research in Humid Tropics Vegetation, Kuching, 1965). It is therefore likely that rainfall was less than half the 2,500 mm received today during the period represented by zone F, though mean annual temperatures may have been little different from present day values. In zone E, higher percentages of Urticaceae/Moraceae and *Elaeocarpus* pollen at the expense of pollen from rain forest gymnosperm and sclerophyll taxa, as well as an increase in the total number of dry land taxa represented, indicate an increase in complexity of the surrounding vegetation. Complex Notophyll Vine forest with *Araucaria* probably replaced Low Microphyll Vine forest with *Araucaria* under increased precipitation (approximately 1,400 mm yr^{-1}). Zone D is very similar floristically to zone F and this suggests a return to Low Microphyll Vine forest under reduced rainfall.

The transition from Low Microphyll Vine forest to Sclerophyll vegetation occurred between about 38,000 and 27,000 years BP. The reason for this change could be a further decrease in precipitation but man, with his use of fire, may also have had an important effect, for it is now known that he has been in Australia for at least the past 32,000 yr (ref. 5). During the period of maximum sclerophyll expansion, rain forest patches which are not extensive today along the east coastal areas of Australia must have been very much restricted in area, and many rain forest types probably survived in stream gullies and other favourable retreats.

At some time before 7,000 BP, rain forest again invaded

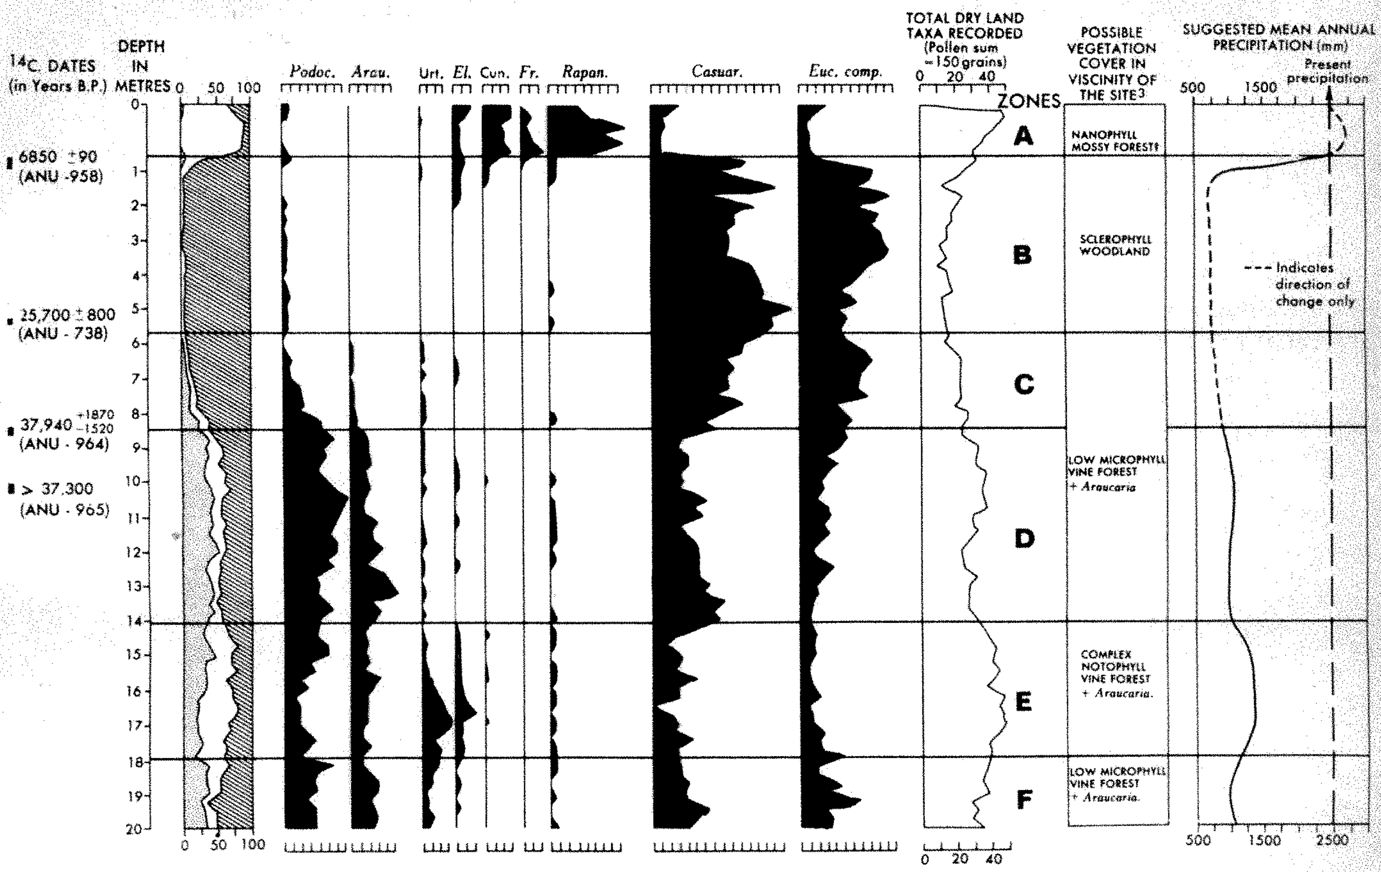

Fig. 2 Pollen diagram from Lynch's Crater. The column on the left shows the percentage of rain forest gymnosperms (stippled); rain forest angiosperms (white); sclerophyll taxa (hatched). The frequencies of pollen of all taxa are shown as percentages of the dry land plant pollen total; each division represents 5% of the pollen sum. Abbreviations for taxa: *Podoc.* = *Podocarpus; Arau.* = *Araucaria;* Urt. = Urticaceae/Moraceae: *El.* = *Elaeocarpus;* Cun. = Cunoniaceae; *Fr.* = *Freycinnettia; Rapan.* = *Rapanea; Casuar.* = *Casuariana; Euc. comp.* = *Eucalyptus comp.*

the area, certainly as a result of increased precipitation. High values of *Rapanea*, Cunoniaceae and *Freycinnettia* strongly suggest cooler and effectively wetter conditions than those pertaining today. The vegetation was probably a form of cool temperate rain forest (Nanophyll Mossy forest) and the absence of *Nothofagus* from this suggests that it had already become extinct in the region. The slight increase in sclerophyll pollen in the most recent spectrum possibly represents a decrease in effective precipitation towards the present day level. A more detailed interpretation of this zone is impossible at the moment as it is not known whether the pollen sequence is very condensed or whether the mud failed to accumulate through much of the period.

From the results presented, it is evident that climatic changes have occurred in north-east Australia of a magnitude similar to those of glaciated higher latitudes. The main variable, however, has been shown to be rainfall, with the latter part of the Pleistocene effectively drier than the Holocene. The effects of these climatic changes on the vegetation have been dramatic, three major vegetation types having been represented on the Atherton Tableland within the last 60,000 yr.

Work on Lynch's Crater is continuing; recent drilling has extended the recovery of core material beyond 40 m from the surface and still the deepest organic sediments have not been reached. When pollen from the total depth of material has eventually been analysed, the information recovered will provide a record of vegetation and climatic changes occurring through one or several complete glacial cycles and permit an informed assessment of the status of present-day vegetation patterns within the region.

I thank the Australian National University for supporting this work, Messrs A. and K. Anderson for permission to carry out field work on their property, Professor D. Walker and Dr J. M. Powell for advice and the staff of this department for assistance.

Experimental allergic neuritis induced by sensory nerve myelin may provide a model for nonlepromatous leprosy

Experimental allergic neuritis (EAN) is induced by the injection of peripheral nerve myelin and Freund's complete adjuvant into experimental animals[1]. It is characterised clinically by an acute motor paralysis accompanied by ataxia, both of which vary in severity from a mild to an extremely severe form. Histology shows focal areas of demyelination and mononuclear cell infiltration confined to the peripheral nervous system (PNS). It is one of a group of autoimmune delayed hypersensitivity conditions which are specific for target tissue but not for species. Experimental allergic encephalitis (EAE) is also an experimentally induced paralysing disease, but in this case the pathology is confined to the central nervous system (CNS). It is induced by injection of myelin of central nervous system origin in Freund's adjuvant. The observation that myelin from the CNS produced lesions confined to the CNS, whereas that from peripheral nerves produced lesions in the PNS has now been explained on the basis of biochemical differences between myelin from the two sites of origin[2,3].

Patients with nonlepromatous (tuberculoid or borderline) leprosy can develop acute sensory loss with selective involvement of superficial sensory modalities[4]. In such patients *Mycobacteria leprae* are few in number. In lepromatous leprosy, although bacteria are abundant, sensory loss occurs late in the disease, at a time when the bacteria have become scarce. This raises the possibility that the sensory loss may be an autoimmune reaction to target sensory nerve supplying the skin. If this is so it should be possible to demonstrate differences in antigenic properties between myelin from peripheral sensory (sural) nerve and that from mixed (sciatic) nerve, which we have previously used to produce EAN[5]. This might prove an experimental model for studying nonlepromatous leprosy. We report here some initial findings after observing for up to nine months, rabbits and rats which were injected with sural nerve in Freund's adjuvant. In all 9 rabbits and in 8 out of 16 rats, skin lesions suggestive of nonlepromatous leprosy were produced.

Human sural nerve obtained *post mortem* was used as antigen. Details of preparation are described elsewhere[5]. In nine Dutch Bantam rabbits 0.2 ml of the suspension was injected into the footpad of one hind limb and 0.05—0.1 ml injected similarly into 16 Sprague Dawley rats. Biopsies of skin lesions were taken from eight rabbits and four rats.

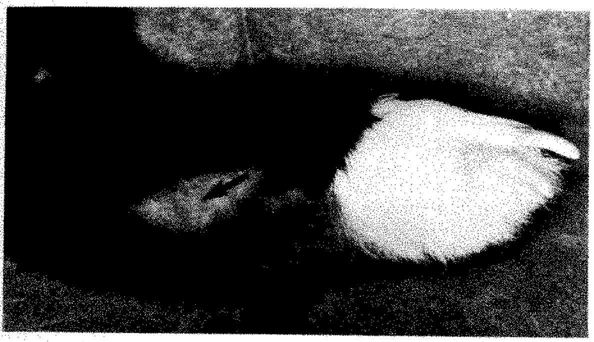

Fig. 1 Skin lesion of 3 week duration on dorsum of rabbit's foot 2 months after injection into same foot pad.

After 4 to 5 weeks the rabbits began to develop discrete skin lesions (Fig. 1) marked by loss of hair without skin ulceration. In some animals with coloured hair, there was a loss of pigment, which was sometimes incomplete, so that patches of hair were light orange, brown, or light grey. The initial lesions were mainly on the injected limbs but later they appeared on the face, other limbs, and dorsum of trunk. Most of the patches were transient, healing after several weeks, but a few have persisted for as long as 3 months. In some the hair began to grow again from the centre. The patches occurred in all nine rabbits, the total number of patches being 30. Some appeared as late as 6 months after injection. Similar denuded patches were observed in the rats. They occurred rather later and were seen in five out of six animals observed for 8 months, and in 10 rats under observations for the past 5 months three have developed patches. The total number was 12. Again some appeared as late as 7 months after injection. None appeared at the injection site. All the limb lesions occurred on the extensor surface, except two which overlapped slightly on to the flexor surface of the hind limb. Only one trunk patch was on the ventral surface. In six rabbits there was also analgesia to pinprick which was predominantly in the hind limbs and distal in distribution. In rats no convincing analgesia could be demonstrated.

Six of the nine rabbits also developed ataxia, with some motor loss, similar to that seen in EAN, when sciatic nerve was used as antigen source. Two of these animals died. The other four recovered from motor symptoms within 3 weeks. None of the 16 rats, including the eight with skin lesions, showed any ataxia or motor loss. Biopsy of the skin lesions showed erosion and disappearance of hair follicles in the early lesions. In a few there was also granuloma formation with mononuclear cells surrounded by lymphocytes. Dermal nerves showed a mononuclear cell infiltrate.

The clinical picture in the rabbits and rats using myelin from the purely sensory sural nerve as a source of antigen showed distinct differences from that seen when mixed (sciatic) nerve is used. The characteristic skin lesions which we have described have not been reported with sciatic nerve as antigen. Also the ataxia and motor loss which is such a prominent feature of the sciatic group did not occur in any of the rats although it did occur in six of the nine rabbits. In the sensory group the skin lesions appeared later than the classical EAN motor and ataxic signs and often ran a more prolonged course.

On this evidence different types of peripheral nerves may be assumed to differ from one another in antigenic potentiality. Biochemical analysis of the myelin from sural nerve has not been reported, but differences have been reported between sciatic nerve, dorsal roots and brachial plexus in the same species[6]; also the ultrastructural appearance varies slightly between fibres of different sizes in the CNS (ref. 7) and there are variations in the electrophoretic protein pattern of myelin from different parts of the CNS (ref. 8). EAN arising from injection of sciatic nerve has been suggested as a model for Guillain-Barré polyneuritis, a predominantly motor syndrome. The 'sensory' EAN which we have described resembles more closely the clinical and pathological features seen in nonlepromatous leprosy. The outstanding features of both are the discrete skin lesions characterised by lack of pigmentation, depilation, and healing from the centre, with a predeliction for the extensor surfaces[9]. Histologically our experimental skin lesions resemble those of early human leprosy[10], with erosion of hair follicles and mononuclear cell infiltration of dermal nerves. In a few of the experimental lesions there was also granuloma formation with mononuclear cells surrounded by lymphocytes.

Skin lesions similar to those in nonlepromatous leprosy have not previously been produced experimentally. The presence of lymphocytes in such skin lesions has been taken as evidence of a cell-mediated immune response directly to *M. leprae*[11]. But the injection of viable *M. leprae* into mice has failed to reproduce these skin lesions[12]. Our experiments suggest instead that *M. leprae* attack the Schwann cell or myelin of sensory peripheral nerves with release of antigen, the immune response of the patient being directed specifically against this antigen. The skin lesions of nonlepromatous leprosy are therefore essentially an autoimmune response to sensory cutaneous peripheral nerve.

Functional and anatomical correlation of afferent responses from the isolated semicircular canal

THE semicircular canal is considered classically to be a sensor of angular head motion during animal navigation; however, the functional significance of the canal's morphology and innervation for transduction and encoding of specific head trajectories is unclear. Neural responses from single afferent fibres innervating the crista of isolated elasmobranch labyrinths were used by Groen *et al.* to determine linear system coefficients of an overdamped pendulum equation, considered to reflect directly the dynamics of the motion of the cupula–endolymphatic fluid in the ampulla[1]. Similar studies on other preparations revealed certain neural response characteristics that were at variance with simple pendulum models, and these differences were ascribed variously to differences in hair cell physiology and afferent or efferent innervation properties, whose effects were superimposed on the fundamental fluid pendulum dynamics[2–4]. But in addition to these hypotheses based on cellular influences, the topological organisation of the receptor could result in specific afferent response characteristics deriving from different anatomical regions within the crista. As evidence for the latter, we report diverse classes of afferent responses, describable by distinctly different linear system equations, that are correlated with the position of separate bundles innervating specific areas of the crista of the guitarfish, *Rhinobatos productus* (Fig. 1).

The horizontal ampullary nerve (HAN) separates from the utricular nerve as six to eight individual bundles which curve and proceed dorsally toward the ampulla (Fig. 1*a*). We counted myelinated fibres in the entire HAN of four preparations and found a mean of 1,359 (range 1,297–1,459) fibres. The individual nerve bundles varied in size, but the rostral-most and caudal-most generally contained fewer fibres (mean: 176, range: 87–367) relative to the central bundles (mean: 288, range: 201–577).

The individual nerve bundles, which appeared to retain their relative spatial distribution, converged near the ampulla, forming a nerve trunk which coursed along the major axis of the saddle-shaped crista (Fig. 6 in ref. 5) from its ventral to its dorsal extremities (Fig. 1*a*). In histological section planes through this major axis (receptor cells and nerves sectioned longitudinally), fibres nearest the crista separated and arched toward the hair cells lining the surface of the ventral planum semilunatum. The remaining fibres cascaded upward progressively along the ridge of the crista and finally projected into the dorsal planum semilunatum (Fig. 1*b*). Hence, fibres from the nerve trunk projected systematically to the crista along its ventral–dorsal axis.

A systematic projection of nerve fibres appeared also across the crista along a minor axis in the plane showing cross sections of both the nerve trunk and the crista (a rostral–caudal plane, Fig. 1*c*). Nerve fibres from the caudal portion of the nerve trunk were traced in serial sections to hair cells on the canal (caudal) slope, fibres from the central region to the crest of the ridge, and those from the rostral portion to the utricular (rostral) slope. This distribution of fibres was also apparent with a dissecting microscope. On the basis of microdissections and histological preparations, we conclude that a systematic pattern of innervation exists along both the major and minor axes of the horizontal crista.

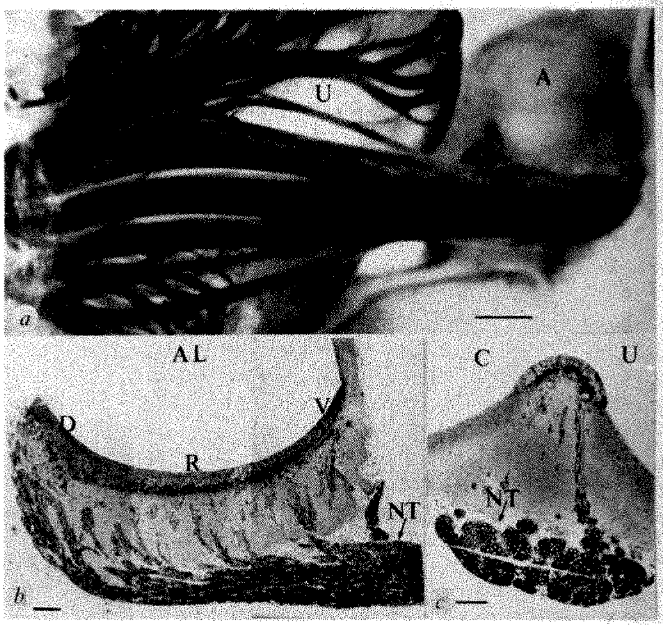

Fig. 1 *a*, Photomicrograph of the right horizontal ampullary nerve innervating the horizontal ampulla (A) of the guitarfish semicircular canal. Intact labyrinth specimens were stained with Sudan black B to facilitate microdissections. The ampullary nerves separate from those of the utricle (U) as individual bundles (numbered in a rostral–caudal sequence) which project dorsally to converge into a nerve trunk (NT) as they approach the ampulla. The nerve trunk courses along the long axis of the crista. The saddle-shaped horizontal crista projects into the ampulla in a medial-lateral plane at nearly right angles to the plane of this figure. The marker equals 0.2 mm. *b*, A longitudinal section through the centre of the left ampullary lumen (AL) and the sensory region, the crista (V,R,D). Labyrinths for histological preparation were fixed *in situ* with glutaraldehyde-paraformaldehyde in 0.1 M phosphate buffer containing 10% sucrose after cervical dislocation and rapid removal of the surrounding cartilage. After embedding in Araldite 502, the tissue was sectioned at 0.5 μm and stained with aqueous toluidine blue. The plane of this figure is rotated 90° about the long axis of the crista relative to (*a*). Fibres from the nerve trunk (NT) closest to the crista separate and cascade systematically toward the receptor cells, first to the ventral planum semilunatum (V), then along the ridge (R), and finally to the dorsal planum semilunatum (D). The marker equals 0.1 mm. *c*, A cross section of the nerve trunk (NT) and the crista. The plane of this section is perpendicular to the minor axis of the crista and oriented 90° relative to the plane of (*b*). The nerve fibres project from the anterior portion of the nerve trunk toward receptor cells on the slope facing the utricular opening of the semicircular canal (that is, rostrally). The marker equals 0.1 mm.

We recorded single-unit spike trains by suspending severed nerve sub-bundles in air with a forceps electrode[1]. Spike trains were amplified, transmitted by means of frequency modulation telemetry, recorded and displayed conventionally. The preparation was aligned on the rotational axis of a Goerz/Inland rotating table (model 800) with the horizontal semicircular canal plane oriented parallel to that of the table.

We developed a new technique to characterise sensory systems on-line by cross-correlating their afferent response to a white noise pseudorandom binary acceleration stimulus (PRBS)[6-8]. Cross-correlations of the spike train responses with six to sixteen periods of the PRBS stimulus were computed on-line and scaled appropriately to obtain estimates of the linear system unit impulse response (UIR) for each afferent[9]. The PRBS input afforded significant advantages over the use of conventional deterministic inputs (for example, sinusoidal and constant acceleration): accurate small-signal linear characteristics were determined over wide bandwidths in a fraction of the time required for conventional techniques, and other noise sources that were uncorrelated with the input did not corrupt the cross-correlated results[7,10]. The accuracy of the UIR as an estimator of the afferent input–output characteristics was tested by observing whether responses to other inputs could be predicted correctly by linear convolution[9,10]. Conventional inputs were applied experimentally in addition to the PRBS input, and the percentage mean-square-error (% MSE) of the predicted and experimental outputs was computed. Most units showed a sufficiently small % MSE (<15%) to justify using linear estimation for this system.

Our analysis is based on results from 120 cells. We found a pattern of organisation in the UIR characteristics that was correlated with relative position of the parent bundles (Fig. 2). Responses from central bundles, for example, 3 and 4 in Fig. 1*a*, had the form shown in Fig. 2a–c; an initial deflection followed by a decay toward the baseline with a slight overshoot indicative of adaption[2]. In contrast, the responses from the rostral and caudal bundles, for example, 1 and 6 in Fig. 1*a*, had the contours shown in Fig. 2d–f: a resolvable rising component followed by a slower decay toward the baseline analogous to an overdamped second-order linear system impulse response[11]. Responses from bundles 2 and 5 were mixed and included all contours shown in Fig. 2. Variability was found in both the relative magnitudes of the initial points and the time constants of the rise and decay components as determined by a nonlinear regression program. The peak amplitudes of all responses from bundles 1 and 6 were similar to those in Fig. 2d–f, indicating lower sensitivities in these afferents relative to those from central bundles. We conclude that the type of response was indeed correlated with relative location of the parent bundles which project to specific anatomical regions of the crista.

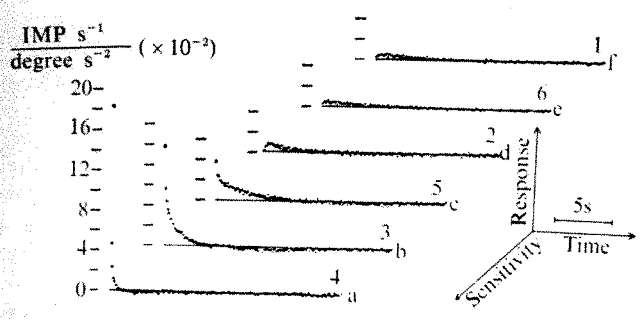

Fig. 2 Linear system impulse response estimates obtained by cross-correlating pseudorandom binary white noise inputs with spike train outputs from six afferents innervating the left horizontal semicircular canal of the guitarfish. Isolated labyrinths were prepared for afferent response recording by pithing the brain, removing the cranium and cartilage at the rear of the orbit to expose the horizontal ampullary nerve, and mounting the labyrinth on a rotating table. A pseudorandom binary sequence (PRBS) with white noise properties, generated by a PDP-11 computer program, was converted to a sequence of rotational accelerations of magnitude ± 100 degree s^{-2} and direction that varied randomly within each PRBS period. The stimulus pattern was repeated periodically with a period $N\Delta t$ as determined by the duration Δt of individual PRBS states and the total number N of states in each period. The PRBS stimulus has a spectral density that is theoretically constant (within 3 dB), and is by definition a white noise source over the band from $1/N\Delta t$ to $1/3\Delta t$ Hz, approximately. We used values of $\Delta t = 92$ ms and $N = 255$ to result in a period of 23.5 s and a noise bandwidth from 0.04 to 4 Hz. Correction factors were applied to compensate for input transducer error resulting from the rotating table's finite switching time and the PRBS finite bandwidth. The adjacent points are separated by 92 ms intervals. The relative location of the parent bundle of each afferent is indicated in the figure by number for each response beginning at the most rostral bundle in the nerve fan. Responses (a)–(c) are typical of those from bundles located centrally in the nerve fan (numbered 3 and 4) and exhibit an initial peak of varying magnitude (for example, 18.3 in (a) followed by an approximately exponential decay and overshoot of the baseline. Responses (d)–(f) are typical of those from bundles located at the rostral and caudal extremities of the nerve fan and exhibit a resolvable exponential rise followed by an exponential decay with negligible overshoot of the baseline analogous to an overdamped second-order linear system. Sensitivity is defined arbitrarily as the magnitude of the response predicted (by linear convolution) to a step input of magnitude 1 degree s^{-2} and duration 0.46 s, that is, the sum of the amplitudes of the first five points in each impulse response.

We excluded the possibility that the response diversity derived from time-dependent degenerative changes in the isolated preparation. Long term recordings (3–8 h) from cells showing responses typical of all types shown in Fig. 2 never showed changes in afferent response characteristics of individual cells during these periods. Furthermore, in paired cell recordings obtained simultaneously using separate electrode channels, typical rostral–caudal and central bundle responses were recorded simultaneously, both immediately and several hours after exposure of the nerve.

These results showing a functional and anatomical correlation of semicircular canal afferent responses suggest an alternative to the view that the afferents encode direct responses to mechanically simple fluid-cupula displacements. Specifically, more complex transductive mechanisms could result in local filtering of the receptor's physiological inputs for the purpose of enhanced signal detection. As an analogy, ideal receivers for known signals corrupted by noise, such as occur in radar, use bandpass filters matched to a particular signal in the sense that the latter is detected in the presence of Gaussian noise with a theoretically optimum signal-to-noise ratio[12]. The filter's impulse response is a time-reversal of the matched signal's waveform. The afferent fibres of the semicircular canal could thus be considered an ensemble of bandpass filters that are matched, in a signal detection theory sense, to specific head acceleration trajectories determined by each afferent's impulse response reversed in time. Each afferent could then be considered tuned to a particular range of head accelerations analogous to the afferent encoding of specific stimulus features described for other sensory systems[13].

Dissociation of lymphocyte activating determinants from recognition sites in mouse MLR

PREVIOUSLY, we were able to block mixed lymphocyte reactions (MLR) in man using anti-light chain antibody[1] but we have been unable to confirm this observation in subsequent studies using other anti-light chain sera We have now found that MLR in the mouse is unaffected by a variety of anti-immunoglobulin sera but using alloantisera it has become evident that the stimulator cells, but not the responder lymphocytes, can be blocked

Female mice of 5–6 weeks of age of the following inbred and F_1 hybrid strains were used BALB/c, C57BL, CBA/H, C3H, BALB/c×CBA/H F_1, BALB/c×C57BL F_1, BALB/c×DBA/2 F_1, CBA/H×AKR/J F_1 and BALB/c×C3H F_1 (breeders obtained from the Laboratory Animals Centre, Carshalton, Surrey) Rabbit antisera to mouse immunoglobulins were prepared as described elsewhere[2] BALB/c anti-C57BL and C57BL anti-BALB/c alloantisera were raised by one skin grafting followed by six weekly injections of C57BL and BALB/c spleen cells respectively into male and female recipient mice One spleen was used for six mice C57BL anti-BALB/c serum and BALB/c anti-C57BL serum showed 90% cytotoxicity to a titre of 1/100 and 1/80 respectively Normal BALB/c and C57BL sera as well as all antisera were stored at −40° C

Foetal calf serum (FCS, Difco, Detroit, Michigan), normal sera and mouse antisera were inactivated for 30 min at 56° C The normal mouse sera and alloantisera were absorbed for 2 h in a water bath at 28° C, with CBA/H (Tables 1, 2) or syngeneic (Table 3) spleen cells (1 spleen per ml of serum) to eliminate nonspecific inhibitory factor(s) The spleen cells were washed twice with Eagle's medium (MEM, Wellcome, Beckenham, England), before they were used for absorption

Lymph node suspensions were prepared as previously described[3,4] except that the cells were finally resuspended in equal ratios of RPMI 1640 (Gibco, Grand Island, New York), and Eagle's medium with 5% FCS

Parent and F_1 lymphocytes at the concentrations of $2\ 66\times 10^6$ ml^{-1} were mixed with 5% absorbed normal serum or appropriate antiserum and then mixed in equal volumes to give a final concentration of $2\ 5\times 10^6$ cells ml^{-1} These parent-F_1 MLCs (refs 1 and 5) were set up in 0 5 ml volumes in each E2R culture tube between selected combinations, incompatible for H–2 or M–locus The sera were allowed to remain in the

cultures throughout the experiment The cultures were refed with equal ratios of Eagle's and RPMI with 5% FCS on day 2 ^{14}C–Thymidine incorporation was measured on day 3 5 according to the technique previously described[4,5] Index of stimulation was calculated as counts in parent plus F$_1$ MLC divided by mean value of parent and F$_1$ cultured alone

Rabbit antisera to immunoglobulin light chains, Fab fragment or the various heavy chain subclasses in no instance inhibited MLR between H–2 incompatible cells, if anything, they were at times responsible for some stimulation (Table 4)

Table 1 shows the results of experiments in which the anti H–2 alloantisera directed against the F$_1$ stimulator cells are introduced into H–2 complex incompatible parent-F$_1$ mixed cultures C57BL lymph node cells were responding to BALB/c×C57BL F$_1$ target lymph node cells The antiserum was absorbed with third party (CBA/H) or syngeneic (C57BL) spleen cells Both methods of absorption were equally effective in removing nonspecific inhibitory activity of mouse serum The controls were of two kinds—the third party F$_1$ cell was from BALB/c×CBA/H F$_1$ lymph nodes and the third party MLC involved an unrelated H–2 compatible, M–locus incompatible combination, that is, CBA/H (H–2^k, Mls^b) and CBA/H×AKR/J F$_1$ target (H–2^k/H–2^k, Mls^b/Mls^a) The results show that only when the alloantiserum was directed towards the specificity of stimulating cells was there 'blocking' of MLR (the stimulation was reduced from 11 3 to 2 2 times the background) There was no significant reduction of stimulation with any of the controls Experiments were then done in which the antiserum was specifically directed against the responding cell in MLC Results of representative experiments are shown in Tables 2 and 3 When anti-H–2^d serum (C57BL anti-BALB/c) was directed against the BALB/c (H–2^d) responding cells in MLC, no blocking was obtained with any of the H–2 or M–locus incompatible combinations (Table 2) Similarly, when another antiserum was used (BALB/c anti-C57BL), blocking of MLC was observed only when C57BL antigens were present on the stimulating rather than the responding cells

Our studies therefore do not provide any evidence for the involvement of immunoglobulin determinants (as recognised in the rabbit antisera used) in the recognition of allogeneic cells in mouse MLR Similar negative findings were obtained in attempts to inhibit T-cell cytotoxicity in the P815 mastocytoma system using the same anti-immunoglobulin reagents (W V, I M R, and D B Thomas, unpublished) in agreement with other authors[6] We have shown, however, that H–2 alloantisera directed against the stimulating cell, but not the responding cell, can specifically block MLR We cannot be certain which determinants the serum is reacting against since it is likely to contain antibodies against both the H–2K and H–2D specificity as well as the lymphocyte activating determinants Our first experiments were with sera which had been absorbed with third party cells to remove nonspecific inhibitory factors and while this was unlikely to affect blocking of the stimulating cells, it is possible that antibodies to receptor sites, if present, might have been removed by this procedure This objection was met by showing that selective blocking of stimulating cells was still obtained after absorption of the nonspecific inhibitor with syngeneic cells

If antibodies had in fact been raised against the MLR recognition units then they were not of sufficient titre, avidity or specificity to block the reaction Another interpretation could be that the antisera did in fact react with the receptors of the responding cells but that no inhibition occurred because the blocked receptors were then rapidly shed and new ones synthesised What these results do show is that the activating determinants are distinct from the receptor sites In this sense, the results are in conflict with those of Ceppellini[7] or Thorsby and Solheim[8] in man but are consistent with other findings (J Brochier, I M R, and H F, unpublished) A reason for this discrepancy might lie in the concentration of alloantiserum used by the former authors, if the lymphocyte activating

High frequency of T lineage lymphocytes in nude mouse spleen

CONGENITALLY athymic mice (nude mice) lack the T cell compartment of the lymphoid system[1-3] and their spleen has been extensively used as a source of B cells It has been shown recently, however, that nude mice have a few T cells[4] and precursors for T cells[5] These precursors can repopulate a grafted neonatal thymus and differentiate further[5], migrate to secondary lymphoid organs[5] and restore some T-cell-dependent immunity[6]

Although the T precursors probably originate primarily in the bone marrow, the nude mouse spleen might also contain some precursors Indeed, a variety of treatments renders within a few hours a proportion of nude mouse spleen cells, presumably lymphocytes, susceptible to cytotoxic anti-T lymphocyte antisera[7] Moreover, it is claimed that cultivation of nude mouse spleen cells on thymic reticuloendothelial cell monolayers also induces an important rise in characteristic T cell reactivities[8]

When analysed by immunofluorescence, as many as 40% of nude mouse spleen lymphocytes lack detectable membrane immunoglobulin (Ig), (ref 5 and F L and G E R, unpublished) a B cell marker[9] When reacted with fluorescent mouse antibody directed against the θ antigen[9,10], a T lymphocyte marker[9], up to 20% of nude mouse spleen lymphocytes show a faint fluorescence which is specific (cells are stained with anti-θ–C3H reagents not with anti-θ–AKR) but too weak to be satisfactory In preliminary experiments the detection of θ was amplified by using in sequence anti-θ antibody and rhodamine-labelled anti-mouse Ig, a procedure which also stains the B cells through their surface Ig Calculating the difference between the number of stained cells whether the first step was anti-θ or normal mouse serum, again about 20% of nude mouse spleen lymphocytes seemed definitely to have the θ marker

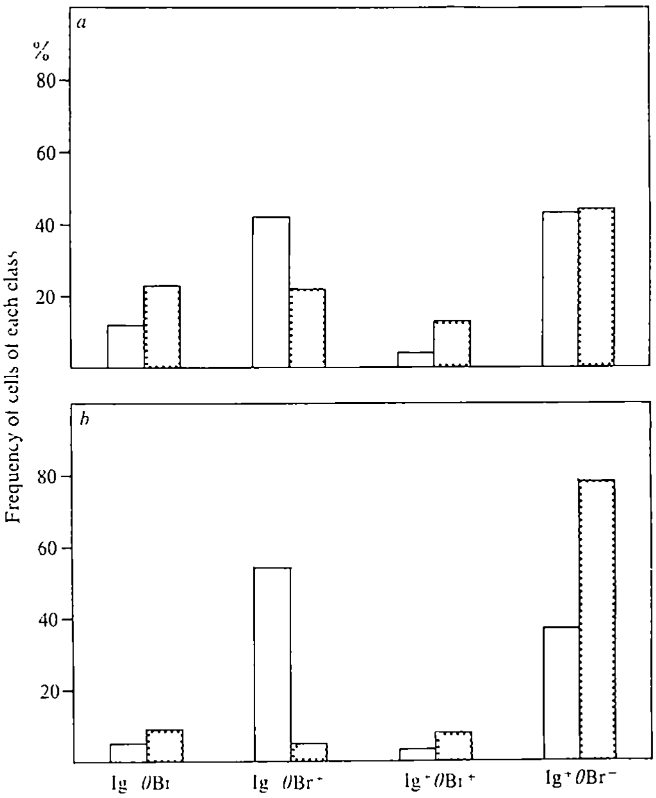

Fig 1 Frequency of cells with or without membrane Ig and/or θBr 2.5×10^6 cells in 0 1 ml medium (RPMI 1640+0 5% BSA+10 mM NaN_3 buffered with 0 03 M HEPES and NaOH to *p*H 7 2) were incubated (30 min, 0° C) with 0 1 ml (50 μg) of RIgG–α–MθBr (NRIgG as control), washed three times, and further incubated (15 min, 0° C) with 0 2 ml of a mixture of TRITC–SIgG–α–RIg (50 μg) and FITC–SIgG–α–MIg (50 μg), washed, and examined for double fluorescence The figure represents mean values of the frequencies of cells from seven normal mice (five BALB/c, two NMRI) and seven nudes (five BALB/c-nu, two NRMI-nu) (at least 500 cells were examined per individual mouse) *a*, Spleen lymphocytes, *b*, lymph node lymphocytes Open columns, normal mice, stippled columns, nude mice For the preparation of RIgG–α–MθBr, immunisation was by two intramuscular injections of 3 CBA/J mouse brain, homogenised in complete Freund's adjuvant at 1 week intervals boosted 5 months later before a wait of 2 weeks and the collection and pooling of immune serum A pool of preimmune serum from 10 rabbits was used as a control The isolation of IgG was by repeated $(NH_4)_2SO_4$ precipitation (1 6 M, 0° C) followed by DEAE-cellulose chromatography (*p*H 6 3, 0 0175 M phosphate buffer) The *in vivo* absorption of the non–α–θ antibody in nude mice BALB/c–nu, fourth backcross Gl Bomholtgard Ltd, Ry, Denmark) was by intraperitoneal injections of 10 mg IgG ml^{-1} per nude mouse, bled out 8–10 h later The isolation of the RIgG from the mouse serum was by the same procedure as above Most of the mouse Ig (90–95%) sticks to the DEAE, the RIgG passes through The IgG was concentrated on Diaflo membrane UM2 up to 10–20 mg ml^{-1} Storage was at 4° C, in PBS+0 5% BSA+10 mM NaN_3 We used RIgG–α–MθBr on cell suspensions at a final concentration of 250 μg ml^{-1} As a control we used NRIgG prepared from the preimmune serum pool and absorbed similarly

To use the amplification provided by indirect fluorescence and at the same time discriminate between B ($Ig^+\theta^-$) and T ($Ig^-\theta^+$) lymphocytes within a single cell preparation we used the anti-θ antibody present in antisera raised in rabbits against the mouse brain associated θ antigen (θBr)[11] after *in vivo* absorption in nude mice (see legend to Fig 1)

The basic technique for the detection of membrane markers on viable cells by immunofluorescent reagents in conditions which do not allow polar redistribution have been described in detail[5,10,12,13] Binding of RIgG–α–MθBr was revealed in indirect immunofluorescence using sheep anti-rabbit Ig antibody conjugated with fluoresceine or tetramethylrhodamine (FITC- and TRITC–SIgG–α–RIg)[12] Mouse membrane Ig was detected with FITC- or TRITC–SIgG–α–MIg[12]

When assayed on thymus, spleen and lymph node cells from normal BALB/c and AKR mice (either sex, 8–12 weeks old, Gl Bomholtgard Ltd, Denmark), the RIgG–α–MθBr stained the expected percentages of T lymphocytes[9] No significant binding of NRIgG was detected The specificity of binding for cells of the T lineage was assessed by performing a double labelling of θ and θBr AKR or BALB/c mouse cells were first stained by TRITC–C3H IgG–α–θAKR or TRITC–AKR IgG–α–θC3H respectively[5,10], then reacted with RIgG–α–MθBr (NRIgG as control) which was further detected by FITC–SIgG–α–RIg The expected proportion of T lymphocytes was labelled in spleen and lymph node cell preparations[9] and those cells were labelled with both reagents Moreover, preincubation of BALB/c or AKR lymph node or spleen cells with AKR–α–θC3H or C3H–α–θAKR alloantiserum (diluted 1 40, 30 min, 0° C) virtually blocked further binding of the RIgG–α–MθBr Normal AKR and C3H sera had no inhibitory activity Thus, the rabbit heteroantibody, although not detectably discriminating between θC3H and θAKR, seems to bind to the same or very close membrane determinant(s) than the mouse alloantibody whose specificity was fully assessed earlier[5,10]

The binding characteristics of RIgG–α–MθBr are similar to those of α–θ alloantibody both bind better to thymus lymphocytes than to peripheral T cells, both give a homogeneous binding appearing as a 'ring' fluorescence when detected by fluorescent monovalent Fab–α–Ig Spots or caps are induced only if a second layer of divalent α–Ig antibody is added

Double staining for Ig and θBr was performed Lymphocytes could be classified into four categories typical B cells having only membrane Ig (Ig$^+$θBr$^-$), typical T cells having only the θ antigen (Ig$^-$θBr$^+$), cells lacking detectable amounts of both markers (Ig$^-$θBr$^-$) and cells expressing both markers (Ig$^+$θBr$^+$) Normal and nude mice (BALB/c, NMRI, BALB/c–nu and NMRI–nu, Gl Bomholtgard, Ry, Denmark) were compared (Fig 1)

In nude mouse spleen the proportion of typical B cells (Ig$^+$θBr$^-$ lymphocytes) is not higher than in normal mouse spleen Interestingly, about one fifth of the lymphocytes are definitely of T lineage (Ig$^-$θBr$^+$) In lymph nodes typical B cells are more frequent in nudes than in normal mice and many fewer lymphocytes are of T lineage In both spleen and lymph nodes the frequency of Ig$^-$θBr$^-$ and Ig$^+$θBr$^+$ is higher in nudes than in normal mice

When spleen cells from a pool of BALB/c–nu were preincubated with AKR–α–θC3H alloantiserum (diluted 1 40 for 30 min at 0° C) there was an 84% reduction in the number of cells binding detectable amounts of RIgG–α–MθBr (compared with preincubation with normal AKR serum) This shows that, as in normal mice, in nude mice RIgG–α–MθBr also binds apparently to the θ antigen itself and not to an undefined 'stem cell antigen'[14,15]

NRIgG did not detectably bind to the cells, except in the case of one NMRI and one NMRI–nu where rare cells picked up NRIgG unspecifically, most of them having also Ig on their surface These false double positive cells accounted for a quarter of those found when the RIgG–α–MθBr was used on the cells from the same animal

Ig$^+$θBr$^-$ cells in both normal and nude mice seem to be typical B lymphocytes and do not require further comment but it is interesting that nude mice have a high frequency of lymphocytes of T lineage The 20% of Ig$^-$θBr$^+$ lymphocytes in nude spleen are not equivalent to those of normal mice, indeed the latter can also be easily detected as θ$^+$ by the mouse α–θ alloantibody used in direct immunofluorescence, while the definite detection of the former depends on the large amplification produced by the indirect immunofluorescence method used These cells have less θ antigen and it is not known if they are still potential precursors or cells of T lineage having followed an aberrant differentiation pathway because of the lack of thymus

Ig$^-$θBr$^-$ cells which might be 'early precursors' have already been described[16,17], but their possible T nature was rejected[17] on the assumption that the only cells of T lineage homing in the spleen have to come from the thymus

The significance of Ig$^+$θBr$^+$ cells is difficult to evaluate as it is not known if both markers are the actual synthetic products of the cells

Cells binding the heavily iodinated synthetic polypeptide (Tyr,Glu)–Ala– –Lys (ref 18) were found among all four cell types indicating that commitment to antigen and receptor expression on cells of T lineage do not require the thymic presence

The various cell types described here, and the possibility of a prethymic differentiation pathway of T cells, clearly need further characterisation It is quite clear, however, that nude mice are not a source of pure B cells, especially when the spleen is used Conclusions on lymphocyte activation based on this assumption might have to be reconsidered

We thank Miss L-B Hagg, Mrs K S Mayor and Miss A Ryden for technical assistance One of us (F L) is Chercheur Qualifie from the Belgian National Funds for Scientific Research The sheep antisera were the gift of Dr A S Kelus

Restriction by H-2 gene complex of transfer of cell-mediated immunity to *Listeria monocytogenes*

RESULTS from three distinct experimental systems indicate that, except for lymphocytes reacting to alloantigens, interaction between sensitised thymus-derived lymphocytes (T cells) and other somatic cells occurs only in syngeneic or semiallogeneic systems First, histoincompatible T cells do not function as helpers for antibody-forming cell precursors (B cells)[1,2] Second, maximal proliferation of lymphocytes (presumably T cells) resulting from exposure *in vitro* of sensitised guinea pig lymphocytes to antigen-pulse macrophages is observed only when the two cell types share major histocompatibility antigens[3] Third, cell-mediated lysis of fibroblasts or macrophages infected with lymphocytic choriomeningitis (LCM) virus, a function of specifically sensitised T cells, occurs only when lymphocyte and target cells share at least one set of H-2 antigenic specificities[4,5] The phenomenon is unaffected by differences either in minor histocompatibility antigens, or at the M locus

Can this restriction be applied more generally as an index of T cell involvement in immunological phenomena? This possibility can be further investigated in another model where T cells are known to play a central part, adoptive transfer of immunity to *Listeria monocytogenes* infection in mice[6-8] Experiments reported here indicate that T cell activity in this experimental system is also restricted by the H-2 gene complex

The strain of *Listeria monocytogenes*, and methods used for immunisation, cell preparation, cell transfer and enumeration of viable bacteria in individual organs have been described elsewhere[7,9,10] In most experiments $5 0\times10^7$ CBA/H×C57BL F_1 6 d *Listeria* immune or normal cells were injected intravenously (i v) into CBA/H or BALB/c recipients, infected i v 2 h previously with 5×10^3 viable *Listeria* Protective effects were measured quantitatively by determining viable bacterial counts in individual recipient spleens and livers at intervals after cell transfer

Growth kinetics of *Listeria* in CBA/H and BALB/c mice were comparable (controls, Fig 1) Immune CBA×C57BL F_1 cells protected semiallogeneic parental CBA/H much more effectively than allogeneic BALB/c cells (Fig 1) Viable bacterial counts in spleen were a more sensitive indicator of protection than liver counts Therefore although liver counts were also determined, only viable counts in spleen will be presented, the results for liver being essentially similar Transfer of normal cells into infected semiallogeneic or allogeneic recipients had no significant influence on bacterial counts in spleen or liver during the first 2 d In the following experiments recipient mice were killed 42 to 48 h after cell transfer[7,8,10]

The degree of protection of CBA/H or BALB/c mice by adoptively transferred immune CBA/H×C57BL F_1

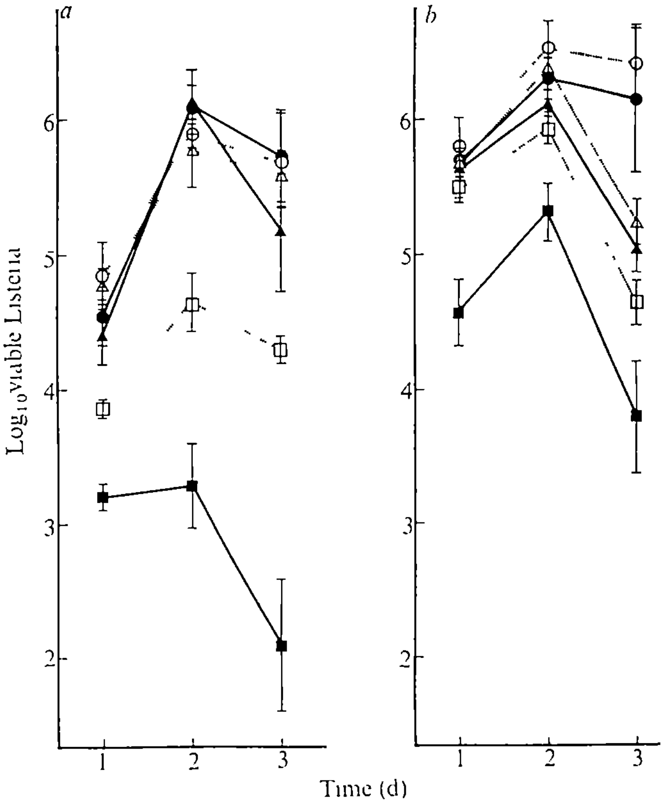

Fig 1 Effect of the transfer of 5×10^7 immune (■, □) or normal (▲, △) spleen cells (CBA/H × C57BL F_1) as compared with controls (●, ○) on the viable counts of *Listeria monocytogenes* in *a*, spleens and *b*, livers of parental strain CBA/H (■, ▲, ●) or allogeneic BALB/c (□, △, ○) recipients infected with 5×10^3 viable bacteria 2 h before cell transfer Each point represents the mean of groups of four to five mice The vertical bars enclose two standard errors of the mean Control mice and normal cell recipient did not differ significantly, except liver counts on day 3 CBA/H $P < 0 05$, BALB/c $P < 0 01$ Protection by immune cells was significant when compared with no cells or normal cells in CBA/H spleens day 1 $P < 0 01$, day 2 $P < 0 001$, day 3 $P < 0 01$, livers day 1 $P < 0 02$, day 2 $P < 0 02$, day 3 $P < 0 05$ For BALB/c spleens day 1 $P < 0 01$ day 2 $P < 0 02$, day 3 $P < 0 02$, livers day 1 $P < 0 05$, day 2 $P < 0 05$, day 3 $P < 0 05$ Difference of protection in CBA/H and BALB/c spleen day 1 $P < 0 01$, day 2 $P < 0 01$ day 3 $P < 0 001$, liver, day 1 $P < 0 05$, day 2 $P < 0 05$, day 3 $P < 0 05$

¶ Significance of protection in syngeneic or semi-allogeneic against allogeneic recipients $P < 0 01$

5×10^7 viable normal or immune spleen cells were transferred to recipients Immune cells were from donors injected with 2–3 $\times10^3$ viable bacteria 6 d previously Recipients were infected with 5×10^3 viable bacteria 2 h before cell transfer Log_{10} viable bacteria were counted in spleens of recipients 42 h after cell transfer spleen cells and the restriction of their efficiency to the semiallogeneic donor–recipient combination are clearly dose dependent (Fig 2) Parental CBA/H mice were protected by 1 7×10^7 or more immune F₁ cells (P<0 001), but not by 6×10^6 cells BALB/c recipients were only protected by 5×10^7 (P<0 01) or more allogeneic immune cells, but to a lesser extent than CBA/H A very high cell dose, 1 5×10^8 immune cells, was obviously not much more efficient than 5×10^7 cells in the semiallogeneic host whereas BALB/c were better protected The two dose-response relationships, plotted on a log/log basis, were linear and parallel over certain dose ranges (Fig 2) The efficiency with which the protection is transferred into semiallogeneic CBA/H and allogeneic BALB/c could therefore be compared and differs by a factor of about 4

Under the chosen conditions 5×10^7 transferred immune cells caused comparable protection in syngeneic or semiallogeneic (F₁ into parent or parent into F₁) hosts and revealed marked restriction of the protective effects in allogeneic recipients (Table 1) As the viable counts in the spleens of control (no cells) mice and of normal cell recipients did not differ significantly in the various strains (except for C57BL), the protective effect of the immune cells could be readily compared

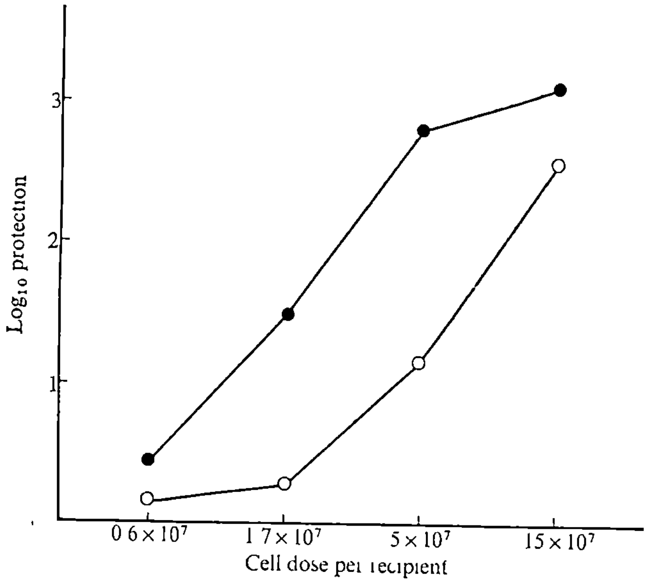

Fig 2 Protection against *Listeria monocytogenes* by the transfer of various doses of immune spleen cells (CBA/H × C57BL F_1) as compared, with normal cells, into parental strain CBA/H (●) or allogeneic BALB/c (○) receipients, determined as the difference of the mean of $\log_{10}$ viable counts in the spleens of groups of four to five mice Significance of difference 0 6 × 10^7 cells n s , 1 7 × 10^7 cells P < 0 02, 5 × 10^7 cells P < 0 01, 1 5 × 10^8 cells n s

The possibility that a difference at the M locus is responsible for this restriction was investigated by transferring DBA/2 *Listeria*-immune spleen cells into DBA/2 and BALB/c recipients Both strains share H-2^d antigenic specificities[11], but differ at the M locus (Table 1, experiment 3) Incompatibility at the M locus had no obvious effect

How can the restriction be explained? As only 40 to 48 h elapse between cell transfer and determination of viable bacterial counts, graft *versus* host (GvH) reactions are unlikely to influence adoptively transferred cells Also the donor recipient combination CBA/H×C57BL F₁ into CBA/H or BALB/c should give comparable conditions for GvH reaction and homing of transferred cells in both recipient strains Furthermore, cytotoxic T cells from mice infected with LCM virus home in comparable numbers to the spleens of LCM infected syngeneic or allogeneic recipients on day 1 after cell transfer (unpublished data)

Events leading to protection against *L monocytogenes* in the recipients of transferred immune cells can be summarised as follows *Listeria* organisms injected i v are taken up by fixed recipient macrophages[9] *Listeria* antigens would thus be present in lesions either as free bacterial antigens or associated with living or dead macrophages Sensitised donor lymphocytes injected later are presumably triggered on contact with the antigen and then probably produce soluble factor(s)[12,13], which activate macrophages to the increased bactericidal activity responsible for protection[9] Donor macrophages play no significant role in protection[6–8]

There are potentially two points in this sequence of events at which restriction by the H-2 gene complex could operate

First, it is possible that the activation of macrophages by a soluble factor only occurs efficiently when macrophages and factor are from the same mouse strain There is no strict precedent for such a phenomenon, but the species specificity of interferon[14,15] and mouse migration inhibition factor (MIF)[16] could be a similar phenomenon This possibility could be readily tested in systems where macrophage activation is achieved *in vitro*[12,13]

Second, as antigens presented on the surface of macrophages trigger T cells more efficiently than soluble antigen[3,4], the alternative possibility is that antigen presented by histoincompatible macrophages fails to trigger T cells efficiently[3] Both possibilities are compatible with the observation that immune allogeneic cells can protect a host if sufficiently large doses of cells are transferred

Similar mechanisms have been proposed in other systems For antigen-induced dose-dependent proliferation of primed lymphocytes by antigen-pulsed macrophages to occur, both cell populations must share histocompatibility antigens[3] When soluble antigen is added in excess, the restriction by histocompatibility antigens is overcome[3] In contrast a secondary *in vitro* anti-DNP response of mouse spleen cells could be triggered equally well by syngeneic and allogeneic macrophages pulsed with DNP-conjugate[17] This could be explained by excess T helper activity being present in the system, thus covering up differences in the efficiency of antigen presentation by histocompatible or incompatible macrophages[3,18]

In conclusion, these results further favour the idea that mouse T cell functions in general may be restricted by the H-2 gene complex

Reactivity of steroid-resistant neonatal thymocytes

THE reactivity of thymus-derived (T) lymphocytes when stimulated with the phytomitogens phytohaemagglutinin (PHA), concanavalin A (con A) and pokeweed mitogen (PWM), correlates well with immunological reactivity Consequently, the mitogens have been useful in studies of the functional maturity of thymocytes in foetal and neonatal mice Reactivity to con A and PWM increases greatly during the perinatal period, but PHA responsiveness reaches a peak shortly before birth and then declines[3] This decline could be due to either (1) reversible suppression of PHA-responsive thymocytes by PHA-unresponsive cells, or (2) the emigration or death of PHA-reactive cells or the immigration or expansion of a population of PHA-unresponsive cells If PHA-responsive thymocytes in the newborn mouse are all steroid resistant, as seems to be the case in the adult[4-6], then steroid treatment of newborns might aid the choice between possibilities (1) and (2) If (1) is correct, steroid treatment should cause a greater increment in thymocyte PHA responsiveness than could be explained by the increased relative number of highly reactive steroid-resistant cells If (2) is correct, steroid treatment should increase PHA-responsiveness in proportion to the increase in relative number of PHA-responsive cells If, however, all PHA-responsive cells are eliminated, steroid treatment should not increase PHA responsiveness This possibility is given some support by a report[5] involving techniques different from ours We have therefore attempted to characterise the fraction of thymocytes surviving steroid treatment in the newborn mouse with regard to mitogen reactivity, reactivity in the mixed lymphocyte reaction (MLR), and surface representation of the θ alloantigen We found that steroid treatment increased the PHA responsiveness of newborn thymocytes, supporting explanation (2)

BALB/c mice about 24 h old were given 100 mg kg^{-1} hydrocortisone acetate intraperitoneally 48 h before death, together with colloidal carbon to mark parathymic lymph nodes, which were discarded Controls were given only colloidal carbon Thymocytes were cultured at 2 × 10^{6} ml^{-1} in microtitre trays for 72 h in RPMI 1640 supplemented with 5% foetal calf serum, 2 mM glutamine, 15 mM HEPES buffer, and 50 μg ml^{-1} gentamicin PHA-P was used at a final concentration of 1 μg ml^{-1}, con A was used at 2 μg ml^{-1}, and PWM at 3 μg ml^{-1} Allogeneic target cells were prepared by incubating C57BL/6 spleen cells for 30 min at 37° C in 40 μg ml^{-1} mitomycin C, followed by three washes in Hanks balanced salt solution (BSS) One microcurie of ^{3}H-thymidine (specific activity 6 7 Ci mmol^{-1}) was added to each culture well 16 h before termination Cultures were collected and ^{3}H-thymidine incorporation into trichloroacetic acid-precipitable material was measured in a scintillation counter

Steroid-treated newborn and adult mice yielded about 16% of the number of thymocytes obtained from untreated controls Table 1 shows a comparison of the mitogen responses of newborn and adult normal and steroid-resistant thymocytes Steroid-resistant newborn thymocytes had substantially more PHA reactivity than normal newborn thymocytes This was true if data were expressed as c p m or as the ratio of experimental to control The increment in reactivity, however, was no more than would be anticipated if steroid-resistant thymocytes were the only PHA-reactive cells in the newborn thymus, that is, the steroid-resistant fraction, constituting about one-sixth of all thymus cells, responded six times as well as unfractionated thymocytes This suggests that diminished PHA reactivity in the neonate is not due to strong reversible suppression by steroid-sensitive thymocytes of the PHA-reactive subpopulation, nor to the absence of PHA-reactive cells due to emigration or cell death

Reactivity of newborn steroid-resistant thymocytes to con A and PWM was substantially greater than that of normal newborn thymocytes As in the case of PHA, the steroid-resistant subpopulation could account for all the con A and PWM-reactive newborn thymocytes

In the adult, steroid-resistant thymocytes had much greater PHA, con A and PWM-reactivity than normal thymocytes As in the newborn, con A and PWM-reactivity in the adult thymus could be accounted for by the steroid-resistant fraction, the steroid-resistant thymocytes were even more reactive to PHA than would be expected These experiments show that there are comparable numbers of mitogen-reactive cells in the newborn and adult thymus after steroid treatment If mitogen responsiveness is used as a marker of T cell maturation, then the newborn thymus, like the adult, contains a small pool of functionally mature T cells

In both newborns and adults, steroid treatment resulted in only a small increment in reactivity to allogenic (C67BL/6) spleen cells, confirming earlier reports[6] This may reflect a paucity of MLR-reactive cells in the thymus, or it may be due to a requirement for more than one effector cell type in the MLR

The ability of thymocytes surviving steroid treatment to absorb the cytotoxic activity of AKR anti-θ C3H serum was used as an index of the relative amount of θ alloantigen expressed on the surface of the cell population A constant number of normal or steroid-resistant thymocytes was incubated with a 1 4 dilution of high titre anti-θ serum for 30 min at 4° C Cells were pelleted by centrifugation, and the residual titre of the supernatant (compared with a control tube containing no cells) assayed against ^{51}Cr-labelled adult BALB/c thymocytes as before[7] Absorption with adult normal thymocytes markedly reduced the cytotoxic titre (Fig 1) of the anti-θ serum, whereas adult steroid-resistant cells caused only a small reduction This confirms reports[8]

Table 1 Mitogen responses of newborn and adult steroid-resistant thymocytes

	No mitogen	PHA	Con A	PWM
Newborn thymocytes	1,099 ± 239	2,203 ± 181	5,509 ± 671	5,885 ± 593
Newborn steroid-resistant thymocytes*	963 ± 157	17,406 ±1,763	35,256 ±6,535	28,265 ±3,336
Adult thymocytes	263 ± 38	1,336 ± 92	18,837 ±1,353	4,201 ±1,067
Adult steroid-resistant thymocytes*	581 ± 285	27,200 ±2,296	28,389 ±3,994	21,792 ±2,204

Numbers represent the means of c p m ± s e of replicates of four per group in one representative experiment Cells were cultured for 72 h with 3H-thymidine added for the final 16 h of culture

* Newborn or adult BALB/c mice received 100 mg kg^{-1} hydrocortisone intraperitoneally 48 h before removal of thymuses for culture

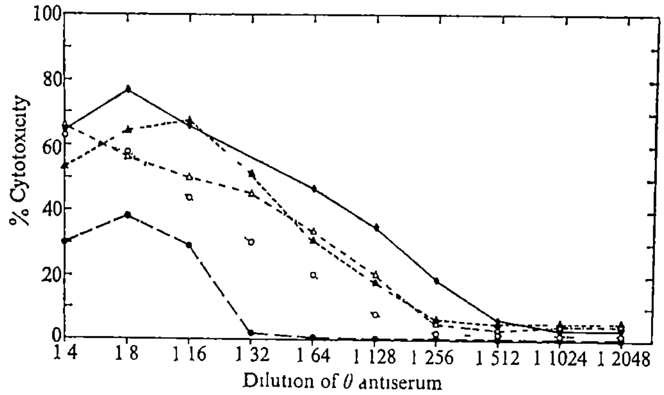

Fig 1 Cytotoxicity curve for anti-θ C3H serum absorbed with different thymocyte populations and then titred against ^{51}Cr-labelled adult thymocytes ⊙, Newborn thymocytes, △, newborn steroid-resistant thymocytes, ●, adult thymocytes, ▲, adult steroid-resistant thymocytes, ◆, unabsorbed anti-θ (C3H)

that normal thymocytes express many θ determinants per cell, while the steroid-resistant subpopulation expresses on the average many fewer θ determinants per cell

In contrast, however, newborn BALB/c thymocytes (mice <24 h old) from normal mice reduced the antiserum titre much less than comparable numbers of adult thymocytes Moreover, steroid treatment caused only a marginal reduction in the ability to absorb anti-θ activity We conclude that newborn thymocytes express somewhat fewer θ determinants per cell than do adult thymocytes, and that, consequently, steroid treatment leads to a smaller shift in the relative θ expression of the surviving subpopulation

Steroid treatment had similar effects on the morphology of newborn and adult thymus, almost obliterating the thymic cortex In newborns, however, we noted a few collections of small lymphocytes in the subcapsular region

We conclude that the potential decline in PHA responsiveness is not due to the selective disappearance from the thymus of PHA-responsive steroid-resistant lymphocytes On the contrary, all the PHA reactivity of the neonatal thymus can be accounted for by the steroid-resistant cells It thus seems unlikely that there are many PHA-reactive cells in the steroid-sensitive fraction comprising 80%–90% of thymocytes Our studies also suggest that the perinatal decline is not due to suppression of PHA-reactive cells by steroid-sensitive thymocytes, for the abolition of such suppression by steroid treatment should have led to a greater increase in PHA reactivity than we observed The decline in PHA responsiveness, then, could be due to dilution of PHA-reactive cells by PHA-unresponsive cells, or to the emigration of PHA-reactive cells from the thymus We cannot distinguish between these possibilities although significant numbers of PHA-reactive cells do not appear in the neonatal spleen until 6 or 7 d after the sudden decline in thymic PHA-responsiveness, arguing against emigration to the spleen Emigration to lymph nodes is a possibility that has not been investigated

The finding that poorly-reactive normal neonatal thymocytes and highly-reactive steroid-resistant neonatal thymocytes appeared to express relatively similar amounts of surface θ alloantigen suggests that in this instance θ does not serve as a marker for cell differentiation, as proposed for the adult thymus[9]

Finally, these data emphasise the relative maturity, at least in terms of mitogen reactivity, of cells in the thymus of newborn mice

We thank Dr William Paul for helpful discussions

Dissociation of EEG and behavioural effects of ethanol provide evidence for a noncholinergic basis of intoxication

IN 1957 it was reported that physotigmine, a drug that potentiates brain acetylcholine by inhibiting the enzyme which normally destroys it, could partially antagonise a tranquilliser, such as chlorpomazine[1] Many years elapsed before anyone tested physostigmine for possible antagonistic effects against other sedative type drugs, such as ethanol Physostigmine given before but not after massive doses of ethanol (4 5 g kg^{-1}) did seem to shorten sleeping time and to reduce death of mice, an observation that led to the conclusion that ethanol might inhibit acetylcholine release or function[2,3]

I thought that this question ought to be examined using more specific measures of ethanol action, in particular the electroencephalogram (EEG) and a battery of behavioural tests for intoxication Such studies revealed that physostigmine blocked ethanol-induced EEG deactivation (changes to high voltage, slower frequencies) but did not prevent behavioural signs of intoxication This to my knowledge is a rare demonstration of dissociation of the EEG and behavioural effects of ethanol, although similar dissociations have been reported for reserpine[4], immobility reflex ("animal hypnosis")[5,6], human hypnosis[7,8], paradoxical or dream stage of sleep[9], and certain comatose disease states of dogs[10–12] and humans[13] The most significant aspect of the ethanol dissociation is that it suggests that intoxication does not primarily involve impairment of cholinergic systems

EEG recording was performed on eight rats, with chronically implanted epidural electrodes bilaterally placed over frontal, parietal, and occipital cortex During recording, rats were free to move within a 25 cm^2 box

Four standard 'catalepsy' tests were used in a separate study of behaviour In one test, a 'cork test', the rat was placed on four corks of diameter 3½ cm, one foot on each, with corks spread 8 cm apart laterally and 10 cm apart longitudinally, catalepsy was scored if feet were not moved for 10 s Two 'platform' tests were used in which both front paws were placed on an elevated platform, either 3 cm high or 9 cm high, catalepsy was defined as holding that position for 10 s Finally, a 'net' test was used in which the rat was placed on a vertically positioned hardware cloth (5 mm square), 25 cm above the floor, catalepsy was defined as staying on the net for 15 s

All drugs were administered intraperitoneally in the following doses physostigmine salicylate (eserine), 0 2 mg kg^{-1} (a 'teeth chattering' dose), neostigmine methylsulphate (0 2 and 0 3 mg kg^{-1}) (the latter caused collapse and was near the fatal limit), and ethanol, 20% v/v aqueous solution, 1 5 and 2 g kg^{-1} (both were intoxicating, with the latter causing the most pronounced EEG signs)

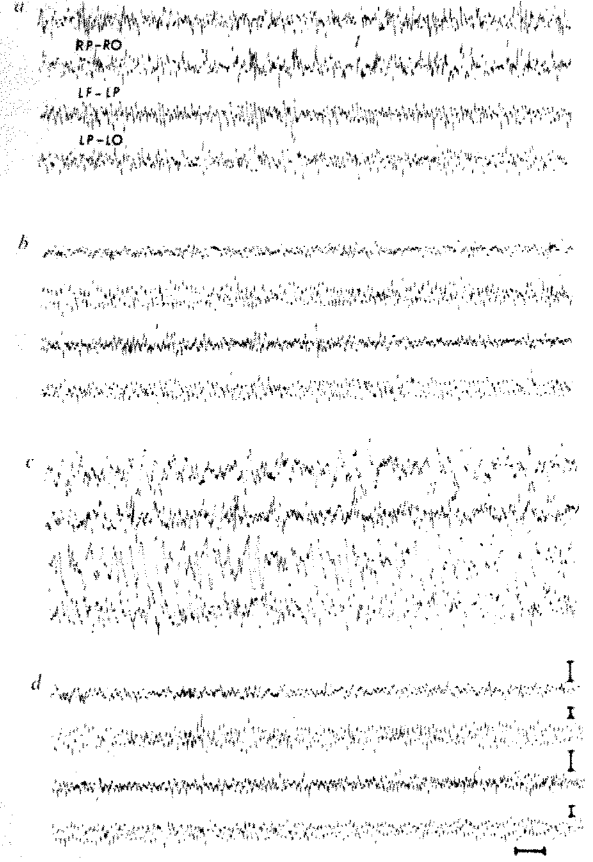

Fig. 1 Representative illustrations of the EEG phenomena exhibited by all rats. All records are from the same freely behaving rat, with 3–4 d between successive trials. *a*, Control records indicate a mildly activated EEG. *b*, Eserine (2 mg kg^{-1}) caused a marked activation (note 6–7 s^{-1} activity) which began 4 min after injection and lasted the full 15 min recording session. *c*, Alcohol (2 mg kg^{-1}) caused pronounced deactivation, beginning 3 min after injection and persisting throughout the recording period. *d*, Administration of eserine 5 min before alcohol injection blocked alcohol-induced deactivation, with EEG activation quite evident for the full 15 min. Behavioural tests of this rat and the others during this eserine + alcohol activation clearly revealed that the rats were behaviourally intoxicated (see Fig. 2). RF, LF = right and left frontal leads: RP, LP = right and left parietal; RO, LO = right and left occipital. Calibrations: 100 μV, 1 s.

Signs of EEG-behavioural dissociation were observed transiently when ethanol alone was given. In all but one rat, both 1.5 g kg^{-1} and 2 g kg^{-1} induced behavioural intoxication during EEG activation that began within 2 to 6 min after injection and lasted at least 1.5 to 10 min for 1.5 g kg^{-1} and 1.5 to 5 min for 2 g kg^{-1}. There are a few reports of ethanol-induced excitatory effects in terms of EEG[14–17] and in terms of enhanced evoked responses[18–21]. Behavioural intoxication during such periods has not been reported, but my rats showed typical subjective signs of intoxication (mild ataxia, hypokinesis, bumping into objects, falling off the edge of a table, flaccid muscle tone and toppling over). During the EEG activation two rats were disconnected from the EEG machine and immediately given the catalepsy tests, which verified their behavioural intoxication.

The EEG-behavioural dissociation was still more conspicuous and readily demonstrated in rats given both physostigmine and ethanol. Physostigmine alone produced persistent EEG activation, beginning within 3 to 8 min and lasting at least 15 min (Fig. 1). When given 5 min before 2 g kg^{-1} ethanol, the EEG activation persisted in every rat for the full 15 min recording period, whereas this dose of ethanol always produced sustained EEG deactivation within 3 to 7 min (Fig. 1). Nonetheless, physostigmine-pretreated rats were clearly intoxicated. Physostigmine not only prevented the EEG deactivating property of ethanol, but to a lesser extent reversed it. Giving physostigmine 5 min after 2 g kg^{-1} of ethanol, at which time the EEG was usually deactivated, caused within several minutes EEG activations which alternated with deactivated periods in some rats. Again, rats displayed subjective signs of intoxication while their EEG was activated.

While it is likely that lower doses of physostigmine would have been less effective in blocking the EEG effect of ethanol the fact that a large dose did block shows there was an antagonism which was restricted to the EEG. A higher dose of physostigmine might in theory have also antagonised the intoxicated behaviour, but such a dose is toxic; in fact, signs of toxicity (shivering, teeth chattering) were universally present at the 0.2 mg kg^{-1} dose. The important point is that there is a dose of physostigmine at which EEG and behavioural effects of ethanol are clearly dissociable.

Physostigmine effects on the EEG were shown to be central, because neostigmine (0.2 and 0.3 mg kg^{-1}), which has the same action but does not cross the blood–brain barrier, failed to produce persistent EEG activation when given alone and of course also failed to prevent ethanol-induced deactivation.

In the battery of catalepsy tests, untreated rats did not show signs of catalepsy, but rats given 2 mg kg^{-1} ethanol failed to move from either the low or high platform (Fig. 2). The unexpected negative results on the cork test seemed due to compulsive slithering movements; rats moved immediately off of the corks and then resumed their hypokinesis. The results of the net test, though quantitatively the same as with saline, were qualitatively quite different. Sixty per cent of saline-injected rats stayed on the net more than 5 s before climbing down; ethanol-injected rats had so little muscle tone that they could not hold on at all.

Eserine, at the dosage used, caused mild teeth chattering, shivering, and hypokinesis (accounting for positive platform tests). The positive results of the net test reflected the skeletal muscle spasms which promoted clutching of the wire by all feet, making removal of the feet difficult.

When eserine and ethanol were given in combination, irrespective of which was given first, the rats displayed all the superficial signs of intoxication, such as ataxia, hypokinesis, and diminished postural tone. These signs were coexistent with the overt signs of eserine effects of shivering and teeth chattering. The failure of eserine to antag-

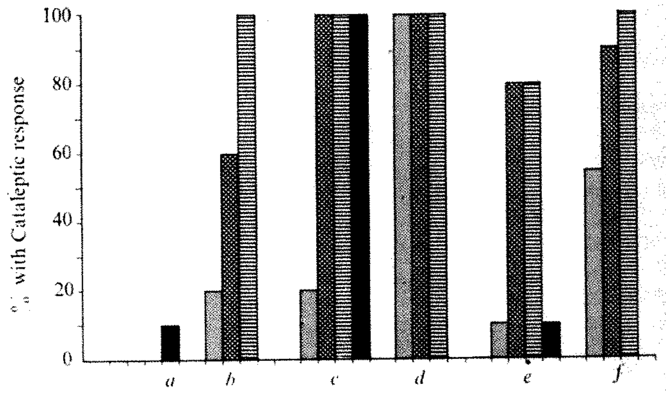

Fig. 2 Behavioural effects of *a*, saline; *b*, alcohol; *c*, eserine; *d*, alcohol and eserine; *e*, neostigmine; *f*, alcohol and neostigmine. Data from the 10 rats per group are expressed as the percentage which shows a cataleptic response, compared to the pretreatment performance of each rat. Vertical bars show the response after each treatment to (from left to right) cork test; 3 cm platform test; 9 cm platform test; net test.

onise the behavioural intoxication was clearly documented in the net test, where all rats fell off the net, because of hypotonia. A surprising and unexplained positive cork test was noted in all rats given the combined treatment.

Neostigmine alone caused rats to fail the net test; rats fell off from apparent weakness, suggesting that much of the body tension caused by eserine was not arising at the neuromuscular junction. As expected, neostigmine when combined with ethanol also caused failure on the net test. There may have been a significant failure ($P<0.05$) on the cork test as well; neostigmine–ethanol treated rats seemed to have a compulsive squirming tendency but were too weak to move, whereas rats treated with eserine and ethanol made no attempts to move.

This work reveals that ethanol caused motor deficits more or less independently of cortical influences. Investigators may have been tempted to ignore subcortical and cerebellar sites as targets of ethanol action because ethanol has been reported to deactivate the EEG in animals with rostral brain stem transections[22]. A noncortical locus is also suggested from studies showing a similar dissociation of EEG and behavioural effects caused by stimulants such as amphetamine[23,24]; such drugs prevented ethanol-induced deactivation of the EEG, but did not prevent behavioural signs of inebriation.

The present work also points to a noncholinergic basis of intoxication. A similar conclusion can be drawn from the recent report that pharmacological manipulation of the cholinergic system did not alter ethanol effects on a discriminated lever-press avoidance task[25].

Such demonstrations of a noncholinergic basis for behavioural intoxication are not really in conflict with a recent report that acetylcholine release is suppressed by ethanol[26]. Such inhibition would account for ethanol-induced EEG deactivation, because acetylcholine mediates neocortical activation (reviewed in ref. 27). But the cortical action of ethanol could be secondary to general decreased neuronal activity, and in any case, it would not necessarily cause behavioural intoxication. Likewise, the motor deficits would not have to be mediated cholinergically. Some recent support for a noncholinergic basis for behavioural intoxication comes from the recent report that physostigmine and atropine did not affect ethanol withdrawal reactions in addicted mice, whereas such reactions were altered by pharmacological manipulation of brain catecholamines and γ-aminobutyric acid[28].

Ultrastructural evidence for foetal liver injury induced by *in utero* exposure to small doses of methylmercury

THE ability of organomercury compounds, particularly methylmercury, to concentrate in tissues of fish and other animals at levels which are toxic for human consumption, is of increasing environmental concern[1–3]. The propensity for mercury compounds to induce morphological, biochemical and enzymatic alterations in the kidneys and the central nervous system is well known[4–8]. Because the liver has been shown to accumulate a large fraction of mercury after administration of methylmercury, it should also be considered a target organ of methylmercury toxicity[9]. Hepatic injury and changes in several hepatic enzyme systems have been reported[10].

Several investigators have shown that methylmercury compounds, when administered to pregnant mice, rats and monkeys rapidly pass through the placenta in the developing foetal tissues[11,12]. Recently, ultrastructural evidence was reported for foetal nephropathy after *in utero* exposure to methylmercury (our unpublished results). We report here, however, the first ultrastructural demonstration of foetal liver injury induced by maternal exposure early in gestation to small doses of methylmercury.

Twenty-four pregnant female Sprague-Dawley rats (average body weight 250 g) were divided into four groups of six animals each, individually housed and permitted free access to water and Purina lab chow. Methylmercuric chloride (CH_3HgCl) was injected subcutaneously into groups 1, 2 and 3 in respective doses of 0.5, 0.75 and 1.0 mg on the ninth day of their gestational cycle. Group 4 control animals similarly received an equal volume of sterile physiological saline.

Neurological symptoms were not observed in pregnant female rats treated with methylmercury and no gross teratological malformations were noted in any of their offspring. Newborn pups were anaesthetised immediately with ether and their livers were excised surgically. Slices of liver were diced into small cubes and immersion fixed in mixture of 2% glutaraldehyde and 0.5% paraformaldehyde in 0.1 M phosphate buffer, *p*H 7.3, for 4 h. They were then rinsed in phosphate buffer, post-fixed in buffered 2% osmium tetroxide, dehydrated in graded ethanol and propylene oxide and embedded in Epon. Thin sections were

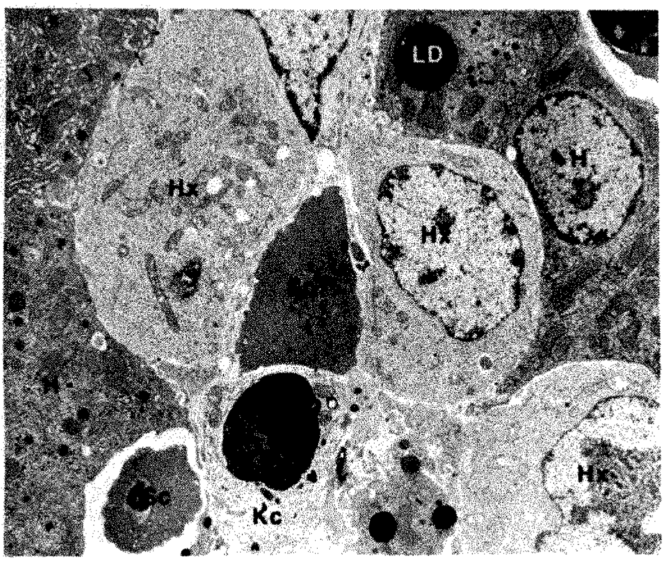

Fig. 1 Foetal hepatic parenchyma after maternal exposure to 1.0 mg CH_3HgCl (3.0 p.p.m. mercury) on the ninth day of gestation. Several hepatocytes (Hx), which are being extruded into the sinusoidal spaces, show an absence of general cellular organelles except for degenerating mitochondria and free ribosomes. Prominent dilation of endoplasmic reticulum (arrows) as well as sinusoidal casts (Sc) of cellular material were also observed. Küpffer cells (Kc) contain giant lysosomes (L). (× 1,860).

counter-stained with uranyl acetate and lead citrate for electron microscopy. Thin coronal sections of the liver were fixed in buffered 10% formalin, dehydrated in ethanol and embedded in paraffin. Sections (5 μm) were stained with haematoxylin and eosin, and by the periodic acid-Schiff technique for light microscopic examination.

Light and electron microscopic evaluation of the foetal liver of animals treated *in utero* with sterile physiological saline revealed no significant morphological alterations. In contrast, foetuses from mothers exposed to methylmercury during gestation presented a consistent pattern of liver injury, the severity and extent of which were dose dependent. The most severe pathological alterations were observed in foetal livers exposed *in utero* to 1.0 mg of CH_3HgCl. At the light microscopic level these changes were confined primarily to hepatocytes and consisted of vacuolation, an increase in lysosomal profiles and in many cases, cellular necrosis.

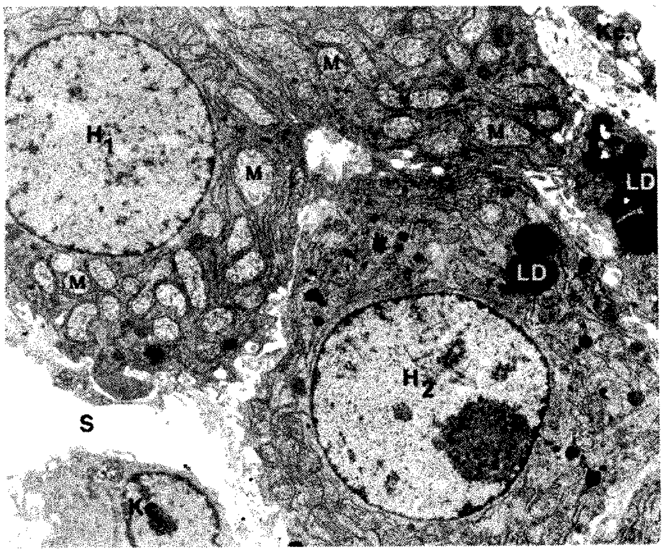

Fig. 2 Foetal hepatocytes after *in utero* exposure to 1.0 mg CH_3HgCl. An increase in lysosomes (L) and lipid droplets (LD) was observed in many hepatocytes. Extrusion of cytoplasmic material from hepatocytes into the sinusoidal spaces was also observed (arrows). Swelling and floccular changes in mitochondria (M) in many hepatocytes (H_1) were observed while mitochondria in some hepatocytes (H_2) appeared normal. (× 4,650).

Electron microscopic examination of foetal hepatocytes revealed, in addition to those changes observed by light microscope, mitochondrial degeneration, occasional accumulations of lipid droplets and dilatation of endoplasmic reticulum. Extrusion of hepatocyte cytoplasmic material into the sinusoidal spaces was also common (Fig. 1). Mitochondrial changes in hepatocytes consisted of an increasing electronlucid floccular matrix, diminution of cristae and occasional swelling (Fig. 2). Similar degeneration of hepatocytes, particularly hepatocyte mitochondria, has been observed in adult rats after methylmercury intoxication[13,14].

Several studies have shown that epithelial cells of renal proximal convoluted tubules accumulate administered mercury in lysosomes and mitochondria[15,16]. Similar accumulation of mercury may be responsible for the hepatic lesions observed under our experimental conditions.

Our results demonstrate a significant causal relationship between maternal exposure to non-teratogenic doses of methyl mercury (1.5 to 3.0 p.p.m. mercury) during gestation and the resulting foetal liver injury. It certainly seems that early gestational exposure of pregnant female rats to minute amounts of methylmercury, which in themselves do not produce maternal neurological symptoms or gross teratology, may constitute considerable risk to the foetus.

Glutathione-oxytocin transhydrogenase of human placental origin with specificity towards neurohypophysial hormones

THE rapid disappearance of endogenous neurohypophysial hormones from the peripheral circulatory system has led many workers to study the mode of inactivation and site of degradation of these polypeptide hormones. Extracts of kidney[1], liver[2,3], pancreas[4], uterus[5], myometrium[6], ovaries[7] and brain and hypothalamic tissue[8] have all been investigated for their ability to destroy the biological activity of oxytocin and vasopressin.

Of the enzyme systems capable of destroying oxytocin, those associated with pregnancy have been the most extensively studied[9]. Fekete[10] first demonstrated that pregnancy serum inactivated the oxytocic activity found in the posterior pituitary lobe and it was later shown[11] that the inactivation of oxytocin and vasopressin extended to fresh extracts of human placentas. Although the placenta is rich in nonspecific aminopeptidases, the enzyme generally known by the name of oxytocinase is considered to be primarily responsible for the inactivation of oxytocin. This enzyme is a cystine aminopeptidase and causes hydrolytic cleavage of the cystine-tyrosine bond in positions 1 and 2, respectively, of the peptide hormone[12].

Branda and Ferrier[13] have described the biological inactivation of oxytocin and deamino-oxytocin by placental extracts. These workers attributed the inactivation of deamino-oxytocin, which is not attacked by cystine aminopeptidase, to the presence of a thiol-protein-disulphide oxidoreductase followed by the action of tissue peptidases. We have examined placental extracts for a transhydrogenase enzyme system and determined its specificity towards the neurohypophysial hormones.

Placentas obtained from normal vaginal deliveries were cut into small pieces and after washing three times in 0.9% (w/v) saline at 4° C, were homogenised in an equal volume of distilled water using an Ultra Turrax T45 homogeniser (Janke and Kunkel Co., Germany). The particulate matter was removed by centrifugation at 1,400*g* for 10 min and further centrifugation of the supernatant at 105,000*g* for 10 min gave a clear placental extract which was used for enzyme assay using various compounds as substrates. Glutathione-protein-disulphide oxidoreductase activity was measured using the substrate at a concentration of 0.13 mM in Tris-HCl (0.1 M, *p*H 8.0) containing EDTA (1 mM). The assay method was based upon that described by Katzen and Stetten[2] in which NADPH (0.5 mg) is oxidised in the presence of reduced gluthathione (16 mM) and glutathione reductase (5 IU). Enzyme activity is calculated from the change in absorbance min^{-1} at 340 nm over a period of 5–6 min.

The glutathione-protein transhydrogenase activity against different disulphide-containing hormones and compounds is shown in Table 1. Of those proteins used as substrates, oxytocin and [8-arginine]-vasopressin were the most readily attacked whereas insulin was reduced to an extent of only 14% that of oxytocin. Cystine, homocystine and penicillamine disulphide were also readily reduced. As a result of the cleavage of the disulphide bond of oxytocin, we have named this enzyme system placental glutathione-oxytocin transhydrogenase.

Fig. 1 Diagrammatic representation of the possible pathways involved in the enzymatic degradation of oxytocin by human placental tissue. *a*, Attack by cystine aminopeptidase; *b*, attack by placental glutathione-oxytocin transhydrogenase.

Table 1 Activity of placental glutathione-protein transhydrogenase with various protein hormones and compounds containing disulphide bonds

Substrate	Relative activity
Oxytocin	100
(8-arginine)-vasopressin	80
Bovine albumin	56
Human chorionic gonadotrophin	53
Human placental lactogen	48
Insulin	14
Cystine	190
Homocystine	140
N-benzyoxycarbonyl cystine	40
Cystamine 2,2′-dithioethylamine	9
Cystine dimethyl ester	152
Cystine dibenzyl ester	30
Cystine di-*p*-nitroanilide	66
Cystine di-β-naphthylamide	49
Penicillamine disulphide	167
Dithiodioacetic acid	38
Dithiodiproprionic acid	27
Dithiodibutyric acid	32
Dithiodibenzoic acid	38
Dithiodiacetic dibutyl ester	66

The activity is expressed as a percentage of the activity with respect to oxytocin.

Inactivation of vasopressin by the kidney[14] and oxytocin by liver homogenates and tissue extracts[4] is now considered to proceed through a transhydrogenase enzyme system[3]. The enzyme system present in the mammalian liver has been shown to possess a reactivity towards insulin[2] which is 14 times greater than the activity using oxytocin and vasopressin as substrates. In this context it is interesting to note that the liver also elaborates a protease which reacts specifically with insulin[15].

Our findings show that the human placenta is similar to that of the liver in having both a proteolytic and transhydrogenase enzyme system specific towards the same substrate, that is cystine aminopeptidase and placental glutathione-oxytocin transhydrogenase. With the evidence of a transhydrogenase enzyme system being present in the placenta, the role of cystine aminopeptidase as being of prime importance in the degradation of oxytocin is now questionable. Oxytocin may be cleaved by two pathways as illustrated diagrammatically in Fig. 1. Cleavage of the disulphide bond by the transhydrogenase system can occur before peptidase action at the cystine–tyrosine residues or proteolytic action may be the initial step. It has not yet been established which of these sequence of events predominates.

Structural and crystallographic observations on hagfish insulin

INSULIN is a well defined globular protein made up of two small peptide chains linked together through disulphide bonds[1,2] It contains an unusually high proportion of hydrophobic residues and thus tends to readily self-associate[3 4] In many species the hormone forms dimers in solution and, in the presence of Zn^{2+}[4] ions, hexamers[4 5] Recently, Hodgkin and coworkers[6,7] have determined the crystal structure of the rhombohedral form of porcine Zn-insulin at 1 9 Å resolution[6,7] Two molecules of insulin occur in the asymmetric unit, related through an approximate twofold axis to form a nearly symmetrical dimer Three such dimers in turn associate through coordination of histidine residues B10 with two zinc ions to form a nearly spherical hexamer In spite of the availability of the amino acid sequences of a wide variety of vertebrate insulins[2,8], however, comparative studies on the detailed structure and modes of association of vertebrate insulins have been lacking

We have recently studied the biosynthesis and structure of insulin in a cyclostome, the Atlantic hagfish (*Myxine glutinosa*)[9,10] The cyclostomes represent highly specialised survivors of the earliest vertebrates, the ostracaderms, and thus probably diverged from the gnathostomian vertebrates about 500 Myr ago The islet organ in this species has been studied both structurally and functionally[11 12] Our interest in the associative behaviour of hagfish insulin arose particularly from the early finding, in primary structure analyses, that aspartic acid replaces histidine at position B10 (ref 10) The crystallographic and sequence data presented here suggest that hagfish insulin forms dimers similar in structure to those of other insulins but does not form hexamers

Islet organs were obtained from 4,200 hagfish at the Kristineberg Marine Biological Station (Fiskebackskil, Sweden) Frozen islets were extracted twice with acid-ethanol, and the extract was fractionally precipitated by a modification of the method of Davoren[13] The insulin-containing precipitate was gel filtered over a 115 × 5 cm BioGel P-30 column (BioRad Corporation) in 3 M acetic acid The insulin and proinsulin[14] fractions were identified by means of a double-antibody radioimmunoassay, using a guinea pig anti-hagfish insulin antibody and iodinated hagfish insulin as a tracer The purity of the BioGel fractions was assessed by polyacrylamide gel electrophoresis and by paper and cellulose thin-layer electrophoresis, the insulin (yield about 10 mg) appeared to be at least 90% pure, the major contaminant probably being a desamido component

Unlike most other insulins, hagfish insulin crystallised readily from a dilute acetone-containing citrate buffer near *p*H 6 0 in the absence of zinc Insulin has previously been observed to crystallise in the absence of zinc only in acidic conditions (*p*H 2–4) (ref 15) The crystallisation procedure was a modification of a micromethod used in the Novo Research (Bagsraerd, Denmark) Two solutions were employed (I) 30 ml 1 M HCl, 160 ml acetone and water to 1 l, (II) 0 1 M sodium citrate containing 160 ml acetone l^{-1} When solutions I and II were mixed in the proportions of 5 4, the final *p*H was about 6 0 100 µg of hagfish insulin was placed in a small, conical Pyrex tube, was dissolved in 20 µl of solution I, and was heated briefly in a water bath (50°–55° C) 16 µl of solution II was then added, and the solution was mixed and warmed to 50°–55° C and then was allowed to cool to 25° C over a period of 12 h In these conditions large tetragonal crystals formed at 25° C or at 4° C within 2 d, even in the presence of 0 01 M EDTA Compositional and electrophoretic analysis of washed crystals revealed only hagfish insulin and the putative desamido form

The crystals were clear bipyramids up to 0 5 mm in length X-ray diffraction data on wet mounted crystals showed that these were tetragonal, space group $P4_12_12$ (or the enantiomorph) (ref 16), with cell dimensions of a = 38 51 Å, c = 85 37 Å If the molecular weight of the monomeric protein is taken to be 5,967, then eight molecules of protein in the cell would give as a specific volume V = 2 65 Å^3 per dalton This value is within the range for proteins reported by Matthews[17], but is considerably larger than the 1 9 Å^3 per dalton calculated for rhombohedral Zn-insulin, suggesting looser packing With eight insulin molecules per tetragonal unit cell in $P4_12_12$ or $P4_32_12$, there is one insulin molecule in the asymmetric unit which may form a perfect dimer across the crystallographic twofold axis, but which could not form a hexamer of the type found by Hodgkin *et al* in porcine zinc-insulin crystals We have collected diffraction data to 2 5 Å on these crystals, and are collaborating with Professor Hodgkin's group in Oxford on a complete crystal structure analysis

The methods used in our laboratory for amino acid sequence analysis have been reported elsewhere[18] Compositional data for hagfish insulin have been reported previously[19]

Fig 1 The amino acid sequence of hagfish and porcine insulins, with substitutions at each position from other known insulins shown for comparison The additional residue of the hagfish B chain might be the result of either an insertion or deletion event at position 29 or 30 or a single base change within the codon corresponding to the first residue (Arg) of the interchain connecting segment of the porcine proinsulin

Amino acid sequence studies were carried out on the S-carboxymethylated or oxidised chains of hagfish insulin separated by electrophoresis or gel filtration These will be reported in detail elsewhere (J D P, S O E, and D F S, unpublished) The results of these studies provide clues to some aspects of the three-dimensional structure of hagfish insulin A comparison of the sequence of hagfish insulin with that of porcine insulin and the cumulative data on individual amino acid substitutions in all known vertebrate insulins[8] is shown in Fig 1

The most striking feature of the hagfish insulin sequence is that, except at position B18, every residue which is invariant among the other known insulins is also conserved in the hagfish sequence These invariant residues include all of the cysteines and most of the hydrophobic residues present at the dimer interface in porcine insulin crystals (that is, B11, B12, B16, B24-27) The substitution of aspartic acid for histidine at position B10 is an important difference that may account for the absence of hexamers in the hagfish insulin crystals (Substitutions at this position are also known to occur in the insulins of the guinea pig and coypu[8], but crystallisation studies have not been reported Islet tissues from these do not contain much zinc[20]) The substitution of phenylalanine and threonine for the hydrophobic residues usually present at positions B1 and B2 may also interfere with hexamer formation Residues A8 to A10 make up a very basic centre similar to that found in some fish insulins[2] Sequence homologies (Fig 1) suggest that the helical regions of the A chain (A2 to A8 and A13 to A20) are similar in the two species and that the α-helical segment of the B chain (B9 to B19) may also be present in the hagfish

From this analysis there emerges a predicted three-dimensional structure of hagfish insulin which is similar to that of known mammalian insulins Major sequence changes are localised in the extended chain regions, positions A8-A12 and the amino end of the B chain (B1-B10) The stretches of α-helix, the cross bridges, and the residues involved in dimerisation, all of which are important structural determinants in porcine insulin, appear to be conserved in hagfish insulin On the other hand, the zinc binding site and other features that may play a role in stabilising a hexamer structure are not well conserved in hagfish insulin, which is in keeping with the tetragonal symmetry of these crystals These predictions appear to be borne out also by a recent study at 6 Å resolution, comparing the structures of hagfish and porcine insulins[21] The functional significance of these differences in terms of either efficient insulin formation or tissue binding are still not clear The conservation of features related to dimerisation, however, may mean that the dimer is a significant functional entity (Although guinea pig insulin has been reported not to form dimers in solution[22], the necessary regions for dimerisation are present and self-association may occur, for example, at an appropriate tissue-receptor site) Further crystallographic analysis of hagfish insulin combined with studies of its biological activity[19] should help to more clearly define those regions and structural features of the insulin molecule that are necessary for its effective receptor interaction and biological activity[21]

Changes in histone methylase activity of rat brain and liver with ageing

No function has been found for the methylation of the ε-N-amino group of lysine in certain histones that have been demonstrated in thymus gland, liver and erythrocytes as well as several other organs[1] It has been suggested, however, that this modification of the histone polypeptide effects the DNA-histone interaction and may be involved in regulating gene expression[1] Methylation appears to be very specific, occurring after histone synthesis is complete[2] Methylation of certain histones can be correlated with development Gershey *et al* reported that 3-methylhistidine was formed more rapidly in immature erythroid cells than in mature erythrocytes[3], and Borun *et al* found that in developing HeLa cells the lysyl residues of F_{2b}, F_3 and F_{2a} histones were methylated mainly in the G_2 phase and during mitosis[4] Methylation of rat brain histones also seems to depend on age After the intraperitoneal injection of L-$^{14}CH_3$-methionine into different age classes of rats we found that only trace amounts of ^{14}C-methyl were incorporated into brain histones after maturity[5] If L-^3H-lysine and L-$^{14}CH_3$-methionine are administered to newborn rats biphasic type decay curves (^3H and ^{14}C) are obtained for all

Table 1 Age dependence of histone methylation in rat brain and liver nuclei

	Specific activity of total histones			
	Brain		Liver	
	d p m mg^{-1}	pmol mg^{-1}	d p m mg^{-1}	pmol mg^{-1}
Newborn	142,000	65	65,000	29
11	260,000	118	51,000	23
21	179,000	81	72,000	32
83	90,000	40	—	—
365	81,000	36	45,000	20
900	26,100	12	28,000	13

Nuclei from 15 g of brain or liver from different age groups were isolated and suspended in 0 32 M sucrose containing 0 1 M potassium phosphate buffer, *p*H 7 5 and 1 0 mM $MgCl_2$ The nuclei were incubated with 100 µCi C^3H_3-S-adenosylmethionine (1 0 Ci mol^{-1}) for 30 min at 37° C The reaction was terminated by chilling to 0° C and the histones purified as previously described[6] The histones were precipitated with acetone and the protein concentration and radioactivity were determined

histone subfractions During brain development (up to 50 d) the arginine-rich histones have a halflife of 32 d while no turnover is observed after maturity as measured by either ^{3}H or ^{14}C decay We now find that the level of the histone methylases and the ability of brain histones to accept methyl groups decreases during ageing Freshly prepared brain and liver nuclei from rats of various ages were incubated with C^3H_3-S-adenosylmethionine The reaction mixtures were chilled to 0° C, the nuclei centrifuged down and extracted three times with 0 14 M NaCl The residue was washed with methanol–chloroform, acetone, acetic acid (*p*H 3 0) and the histones extracted with 0 4 M HCl[6] When L-^{14}C-lysine was added to the reaction mixture no ^{14}C was incorporated into the resultant histones excluding *in vitro* synthesis of histone in our system

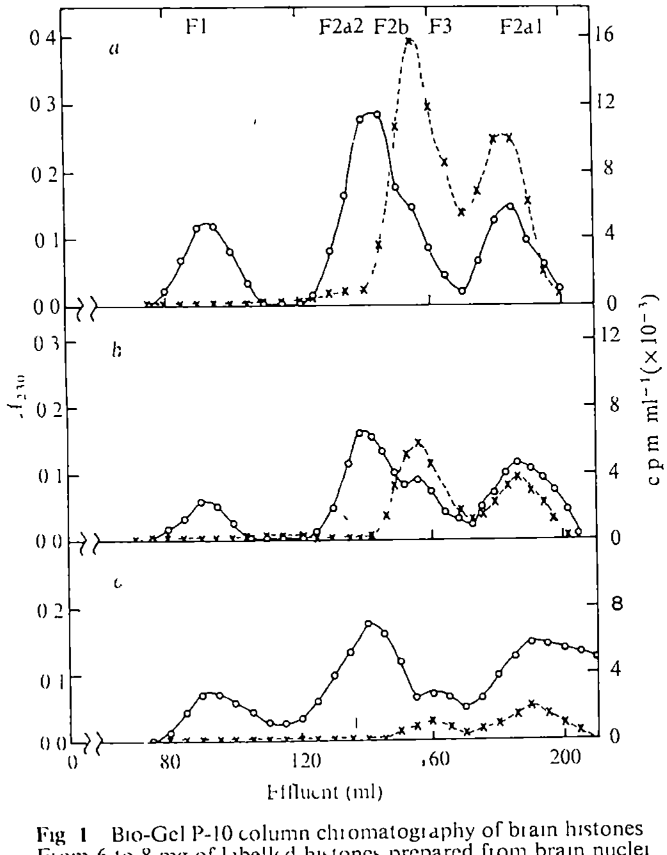

Fig 1 Bio-Gel P-10 column chromatography of brain histones From 6 to 8 mg of labelled histones prepared from brain nuclei as outlined under Table 1 were dissolved in 10 mM HCl containing 6 M urea This solution was applied to a Bio-Gel P-10 column (1 6 350 cm) and the histones eluted with 10 mM HCl Fractions of 3 5 ml were collected Samples of 0 2 to 1 0 ml were taken from each tube for the determination of radioactivity Histones were from newborn rats (*a*), 83-d-old rats (*b*) and 900-d-old rats (*c*)

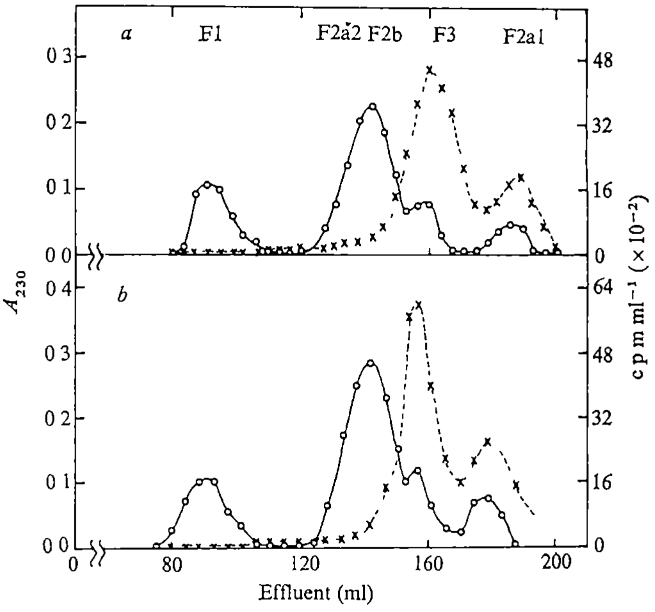

Fig 2 Bio-Gel P-10 column chromatography of liver histones from newborn rats (*a*) and 900-d-old rats (*b*) The labelled histones prepared from liver nuclei (Table 1) were fractionated on Bio-Gel P-10 as outlined under Fig 1

There was an increase in methylation of the histones in brain nuclei during the first few days after birth (Table 1) After approximately 11 d the activity decreased progressively throughout the life of the animal The extent of methylation of histones in intact brain nuclei was three to four times greater during the various developmental stages than in the liver nuclei, while the decrease in activity with ageing was more pronounced in brain nuclei

After fractionation on Bio-Gel P-10 the F_3 and F_{2a1} histones were the only components from brain and liver nuclei found to be highly methylated (Figs 1 and 2) The amount of labelled methyl groups incorporated into the F_3 and F_{2a1} histones decreased during ageing in both liver and brain while the degree of methylation of F_3 was always greater than that of F_{2a1}

After hydrolysis, the products of methylation in the F_{2a1} and F_3 histones were chiefly monomethyllysine and dimethyllysine (Table 2) No methylated arginine or histidine was found in any of the histones analysed In all cases, except the F_{2a1} from liver nuclei of 2 5-yr-old rats, there was more monomethyllsine than dimethyllysine By direct quantitative analysis we find that 8 1% of the lysyl residues in rat liver F_{2a1} histones are methylated, mainly as ε-N-dimethyllysine In F_3 methyl groups are present on 13 4% of the lysyl residues mainly as mono and trimethyllysine in a ratio of 1 1 Tidwell *et al* have also found that ε-N-dimethyllysine is the predominant form in F_{2a1} from rat liver[2] The disproportionately high content of monomethyllysine in F_{2a1} and F_3, as measured by pmol ^{3}H incorporated (Table 2), would be expected if the methyl groups were added sequentially

Table 2 Distribution of methylated lysyl residues in liver histones

Histones	pmol mg^{-1} histone		
	Monomethyllysine	Dimethyllysine	Trimethyllysine
F_3 (newborn)	20 64	8 30	0 70
F_3 (2 5-yr-old)	14 42	5 39	0 19
F_{2a1} (newborn)	16 23	2 48	0 05
F_{2a1} (2 5-yr-old)	5 59	11 70	0 00

The labelled liver histones fractionated on Bio-Gel P-10 (Fig 1) were hydrolysed in 6 0 M HCl for 24 h at 110° C and chromatographed on a column of Beckman PA-35 resin as described previously The level of methylated lysine was calculated from the amount of ^{3}H present under the peaks

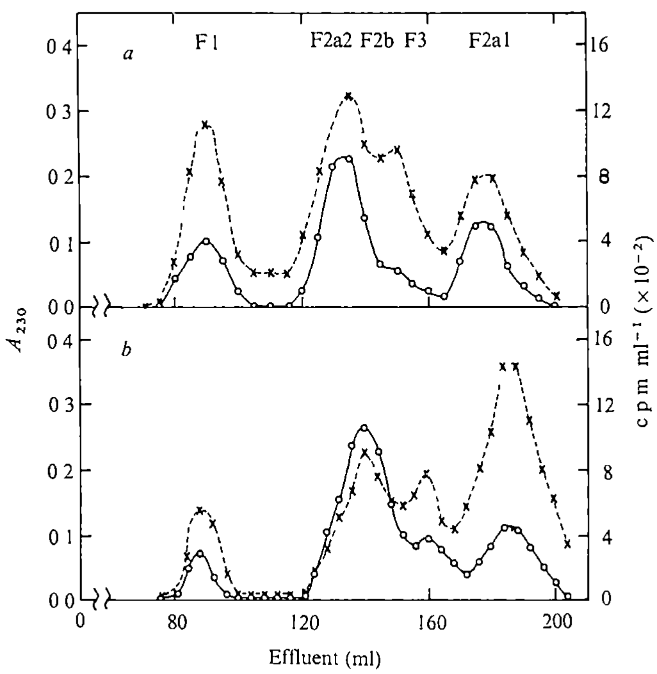

Fig 3 Bio-Gel P-10 column chromatography of brain (*a*) and liver (*b*) histones after incubation with methylases from the same organ Brain histones from 11-d-old rats and liver histones from 21-d-old rats were incubated with methylases from the same organ of 2 5-yr-old animals in the presence of C^{3}H$_3$-S-adenosylmethionine as described under Tables 3 and 4 The histones were fractionated on Bio-Gel P-10 as described under Fig 1

The apparent decrease in methylation of brain and liver histones with age could be due to a decrease in the level of histone methylases and/or the availability of sites on the histones to accept methyl groups To delineate between these two possibilities, histone methylases were assayed in young and old animals using as substrates histones prepared from the same organs

As Tables 3 and 4 show, the histone methylase was considerably more active in extracts of liver and brain nuclei of young animals There was no significant difference in the ability of histones prepared from liver nuclei of young or old animals to accept methyl groups Histones prepared from the brains of young rats were somewhat better methyl group acceptors than those from old brains Our data from both intact nuclei and soluble enzyme preparations agree with those of Paik and Kim[8], who found that histone methylase III, prepared from rat brain, increased after birth until the 10th day and decreased significantly thereafter They used calf thymus histone as substrate and would not have observed differences in the acceptor ability of histones prepared from animals of different ages

Table 3 Histone methylase activity in the brain of young and old rats

Methylase source 1 0 mg	Histone source 1 0 mg	Specific activity d p m mg^{-1}	S-adenosyl-methionine utilised pmol mg^{-1}
Old	Old	11,200	50
Old	Young	17,500	79
Young	Old	24,500	111
Young	Young	32,400	149

The enzyme fractions and histones were prepared from 11 and 900-d-old rats[7] The reaction mixtures contained 50 μCi C^{3}H$_3$-S-adenosylmethionine, 20 mM phosphate buffer *p*H 7 5, 1 0 mM dithiothreitol and 1 0 mg each of histone and enzyme protein from either old or young animals After incubation for 30 min at 37 C the reaction was stopped by adjusting the *p*H to 9 7 with NaOH and the addition of urea 8 M[6] The reaction mixtures were applied to DEAE-cellulose columns (1 0×20) previously equilibrated with 10 mM glycine NaOH buffer, *p*H 9 7, containing 8 M urea The histones were eluted with the same buffer, dialysed against 10 mM HCl and lyophilised The histones were heated at 70 C for 20 min in 1 1 M trichloroacetic acid (TCA), collected on Millipore filters and washed with 1 1 M TCA The precipitates were suspended in 10 ml Bray's counting fluid[9] and the radioactivity was determined using a Packard liquid scintillation counter

Table 4 Histone methylase in the livers of young and old rats

Methylase source 1 0 mg	Histone source 1 0 mg	Specific activity d p m mg^{-1}	S-adenosyl-methionine utilised pmol mg^{-1}
Old	Old	7,130	32
Old	Young	6,100	28
Young	Old	22,760	102
Young	Young	25,000	116

The enzyme fractions and histones were prepared from 21 and 900-d-old rat liver nuclei All other conditions were the same as outlined under Table 3

The labelled histones from our experiments were fractionated on Bio-Gel P-10 and the distribution of methylated components was determined The profiles of brain and liver histones from young animals methylated by the enzyme from old animals are given in Fig 3 All histone subfractions were highly methylated When methylases from brain and liver nuclei of young animals were used the resultant specific activities of the histones were greater but the distribution of label in the subfractions did not change

The distribution of labelled methyl groups in these histones differed significantly from what we observed in experiments with intact nuclei Apparently when the histones are associated with the DNA few, if any, of the lysyl residues on the F_1, F_{2a2} or F_{2b} histones are accessible to the methylases Apparently the specificity for the methylation of the lysyl residues in the polypeptide chain is lost when histones are dissociated from DNA These experiments suggest that some of the specificity for methylation resides within the arrangement of the histones on DNA and that methylation occurs after the histones are bound to the DNA

Immunological distinction between the possible origins of enzymatic activity in a polypeptide fragment of staphylococcal nuclease

WE have used an immunological approach to demonstrate that the residual enzymatic activity in a large polypeptide fragment of staphylococcal nuclease is an intrinsic property of the fragment and not an artefact due to contamination with intact enzyme These results are consistent with present concepts of the folding of polypeptide fragments to form structures similar to the native protein and may offer a method for the investigation of other macromolecular systems

Staphylococcal nuclease consists of a single polypeptide chain of 149 amino acids[1] and has nucleolytic activity towards DNA which is readily measurable spectrophotometrically After trifluoroacetylation to block free amino groups, nuclease can be cleaved by trypsin preferentially at arginine residue 126 (ref 2) Removal of the blocking groups and subsequent chromatographic purifications yield a polypeptide fragment consisting of amino acid residues 1 to 126 (previously designated (1–126) (ref 3, 4)) This fragment contains all amino acid residues of known importance to the active site Spectral measurements of (1–126) indicate an absence of the characteristic ordered secondary structure of nuclease, which suggests the importance of long range tertiary interactions of the distal fragment in the proper folding of the native nuclease molecule[4]

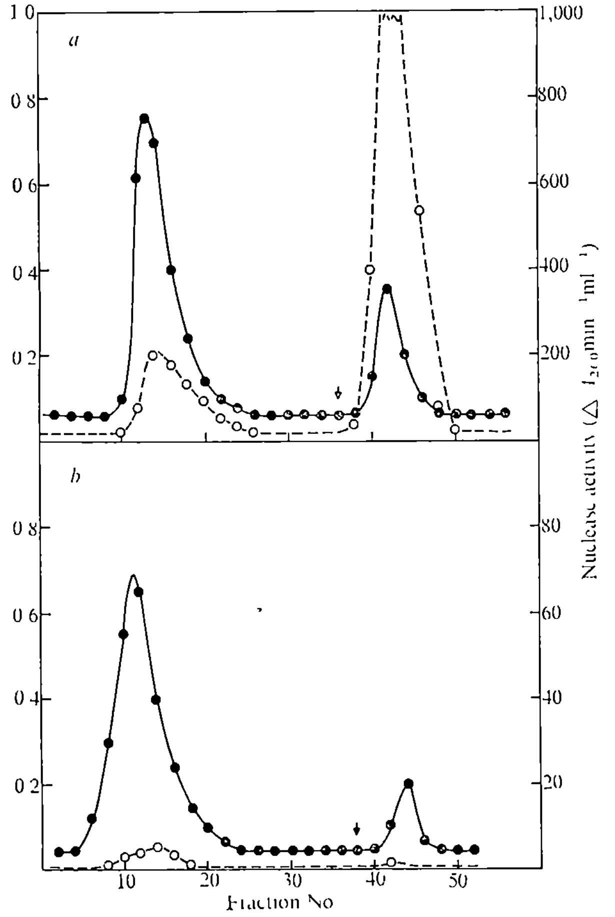

Fig 1 Affinity chromatography of nuclease (*a*) and of (1–126) (*b*) on Sepharose columns bearing the substrate analogue thymidine diphosphate[5] Point of buffer change to effect elution is indicated by arrows in both figures ●–●, Optical density, ○–○, enzymatic activity Note that the acid eluate in (*a*) has the full activity of pure nuclease (a small amount of active material is not bound in these conditions), while the 1–126 adsorbed to the column is of the same activity as that which passes through

But, (1–126) preparations are not devoid of enzymatic activity affinity chromatography on pdTp-Sepharose[5] generally yields a relatively inactive run-through peak followed by pure, active nuclease in the acid-eluted peak (Fig 1*a*) Chromatography of (1–126) preparations yielded peaks in which both the run-through and acid-eluted peaks showed a similar activity/protein ratio (Fig 1*b*) Multiple passages of the first peak through the affinity column decreased the activity of this material to a level about 0 11% that of nuclease, on a molar basis, and which could not be decreased by further passages It is important to know whether this activity is due to contaminating native nuclease or is intrinsic to (1–126) Such intrinsic activity would imply that the correct folding of this fragment to generate an enzymatically active site must occur spontaneously, albeit to a small extent, even in the absence of the tertiary stabilising influence provided by residues 127–149 Unfortunately, most analytical methods do not distinguish between these explanations for the activity of (1–126) The amount of contaminating nuclease that would suffice to produce 0 11% enzymatic activity is too small to detect by analytical gels or by the unique spectral characteristics of nuclease Conversely, the minute fraction of folded (1–126) that might be sufficient to generate this level of enzymatic activity would not be detected spectroscopically

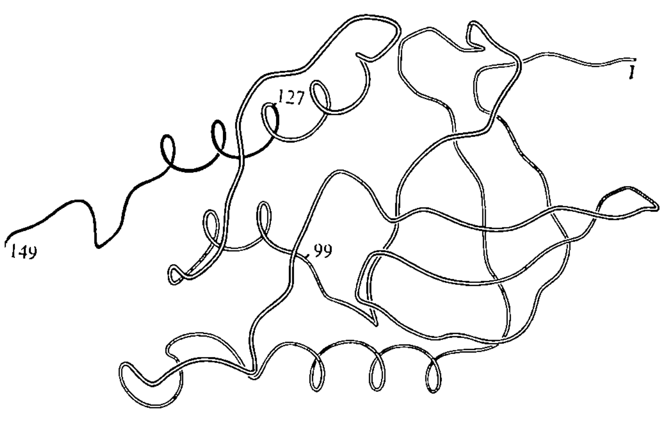

Fig 2 An artist's representation of nuclease with the sequence between amino acids 127 and 149 shaded to indicate the molecular localisation of the antigenic determinant of anti-(127–149)$_{N}$ antibodies

We have therefore used an immunological approach We prepared and fractionated antibodies to nuclease as previously described[6] Briefly, antibodies to the active enzyme were fractionated on Sepharose columns to which selected fragments of nuclease had been bound covalently The antibody fraction resulting from absorption to and elution from Sepharose-(99–149) and then Sepharose-(127–149) has been called anti-(127–149)$_{N}$, the subscript N indicating that the antibodies were prepared by immunising with intact native nuclease Such antibodies combine with nuclease to produce an enzymatically inactive antibody–antigen complex[7] But, since the reaction presumably involves an antigenic determinant in the region 127–149 of the nuclease molecule (Fig 2), such antibodies ought not to react with (1–126)

The effects of anti-(127–149)$_{N}$ antibodies on the activities of nuclease and (1–126) are illustrated in Fig 3 An amount of antibody (5 μg) sufficient to inactivate 12 5 ng of nuclease did not inhibit the activity of 5 μg of (1–126), which contained comparable enzymatic activity As a control against the possibility that the larger amount of protein in the latter case might have interfered with the antibody-antigen interaction, the effect of anti-(127–149)$_{N}$ on a mixture of nuclease and (1–126) was also studied (Fig 3) The antibodies were found to reduce the activity of such mixtures to that which would be predicted for the amount of (1–126) present

Our results indicate then, that the residual enzymatic activity associated with polypeptide fragment (1–126) is an intrinsic property of that fragment and not due to contamination with nuclease We have shown previously that many features of the interactions of purified monospecific anti-nuclease antibodies with fragments of nuclease can be interpreted by a model in which the fragments are presumed to exist in solution in conformational equilibrium between various disordered or random conformations and the conformation assumed by the corresponding amino-acid sequence in the native protein[8] Our present results can also be interpreted by such a model, since a consequence of the native folding of the polypeptide fragment (1–126) would be the native orientation of amino acids of the enzymatic active site, leading to a level of residual activity related to the folded fraction The existence of fragments sufficiently folded to yield activity but with altered K_m and V_{max} values might of course affect the numerical relationship between activity and folding

The hypothesis that the primary sequence of a protein determines its native three-dimensional structure has been substantiated for various proteins[9] However, the mechanism by which the primary sequence is translated into correct folding of a protein is unclear Preferred conformations in terms of φ and ψ angles have been demonstrated at the level of tripeptides[10], and the suggestion that proteins may fold sequentially as they are assembled at the ribosome[11] has been discussed widely The demonstration that antibodies to β-galactosidase can bind to incomplete, ribosome-bound protein fragments has been taken as support for this hypothesis[12] But, the apparent requirement of nearly the entire sequence of most proteins before a significant amount of spontaneous folding occurs has been interpreted as evidence for the importance of long-range tertiary interactions in the folding process[3]

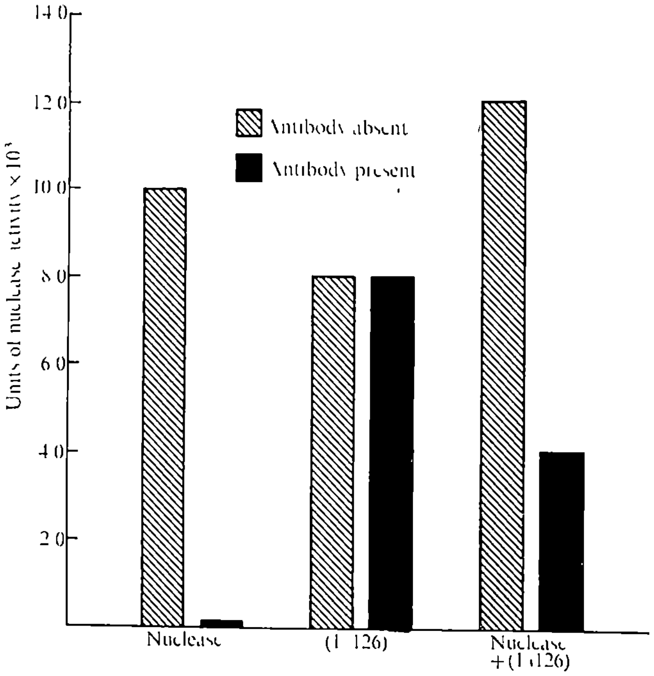

Fig 3 Inhibition of enzymatic activity by anti-(127–149)$_{\text{N}}$ antibodies The first two pairs of bar graphs illustrate samples of nuclease (12 5 ng) or (1–126) (5μg) containing comparable levels of enzymatic activity which were incubated with either saline (control) or with anti-(127–149)$_{\text{N}}$ antibodies (5 μg), and where then assayed for residual enzymatic activity The final pair of bar graphs show the effect of the same amount of antibody on the activity of a mixture of one-half of each of the previous amounts of nuclease and of (1–126) The increased activity of the mixture over that expected from the components may indicate that the complementary sequence of nuclease can affect the folding equilibrium of (1–126), perhaps similar to the folding 'induced' by the fragment (99–149)[4] Antibody reduced the activity of the mixture to a level compatible with the amount of (1–126) in the mixture

The two hypotheses are not necessarily contradictory if one considers polypeptide chains to be undergoing conformational equilibria, since the detection of folded forms depends on the sensitivity of the method of study relative to the position of the equilibrium In terms of mechanism, polypeptides, either on or off ribosomes, can be envisaged as continually trying out different possible three-dimensional conformations The degree to which native format is achieved by an incomplete protein fragment might then be considered a reflection of the relative thermodynamic stability of this conformation as against that of other possible conformations of the same polypeptide chain In the intact protein or in a fairly large polypeptide fragment of that protein, such as (1–126), the ability of the native conformation of the polypeptide sequence to interact with distant portions of the molecule might be expected to increase the thermodynamic stability of that particular conformation Clearly there are many possible three-dimensional conformations of a polypeptide chain of 126 amino acids Thus even the small percentage folding which we propose as the explanation for the intrinsic enzymatic activity of (1-126) represents a considerable restriction of possible conformations of this polypeptide Presumably the sequence of (1–126) permits some, but not all, of the tertiary interactions which lend stability to the native conformation of the intact protein

There are many examples, especially among polypeptide hormones (for example ref 13), where biological activity may be retained in fragments produced by cleavage or synthesis The use of antibodies with specificity for limited regions may help clarify the mechanisms of these phenomena

Haemoglobin Icaria, a new chain-termination mutant which causes α thalassaemia

The human haemoglobin (Hb) variant Constant Spring (Hb CS) occurs in a number of racial groups and is involved in the aetiology of as many as 50% of all cases of Hb H disease, a disorder which presents a major public health problem in south-east Asia[1,2]. It has an elongated α chain of 172 residues which has probably arisen by mutation of the normal α-chain-terminating codon (UAA) at position 142 to a glutamine codon (CAA), allowing read-through into extrastructural codons at the 3′-end of the α mRNA[3]. We report here the characterisation of Hb Icaria, a second Hb with an elongated α chain of 172 residues. Its structure is identical with that of Hb CS except that residue α142 is lysine instead of glutamine.

The variant, which comprised 0·8% of the total Hb, was discovered during the haematological investigation of a woman from the Aegean island of Icaria. Examination of a haemolysate on starch-gel electrophoresis at *p*H 8·5 showed two minor slow-moving haemoglobin components, one cathodal and the other anodal. Comparison with a haemolysate containing Hb CS showed that both minor bands in the Hb Icaria sample were more cathodal than the corresponding bands of Hb CS (Fig. 1).

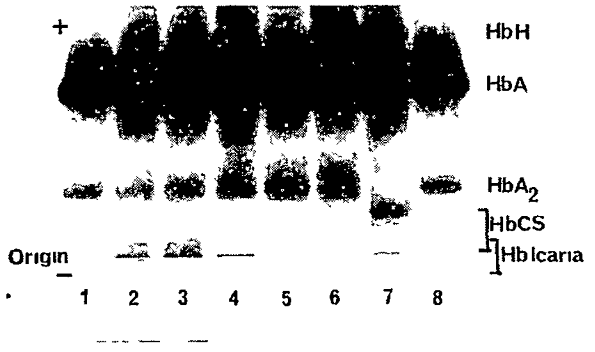

Fig. 1 Starch-gel electrophoresis (Tris-EDTA-borate system, *p*H 8·5, benzidine stain) of red-cell lysates prepared from the following (left to right): 1, normal adult; 2 and 3, Hb Icaria heterozygote; 4 and 5, normal adult; 6, Hb CS heterozygote; 7, individual with Hb H disease and Hb CS; 8, normal adult.

The minor components of Hb Icaria were purified on Amberlite IRC-50 by a procedure similar to that used for the isolation of Hb CS (ref. 3); they remained tightly bound to the top of the column after the elution of Hb A at 25° C with Developer 2. Hb CS, by comparison, remained on the column as a more diffuse band. Both haemoglobins were eluted as a sharp zone by increasing the salt concentration of the Developer 2 buffer to 0·5 M with NaCl. Starch-gel electrophoresis of the purified haemoglobins revealed two major slow-moving components, together with variable amounts of contaminating Hb A. In some preparations it seemed that considerable degradation of the Hb Icaria had taken place, since the mobilities of the slow-moving components were more anodal than in the original haemolysate. This behaviour is similar to that seen occasionally during the purification of Hb CS, and is attributed to degradation of the α-chain 'tail' by red-cell proteases during the purification procedure[3].

A sample of purified Hb Icaria, containing about 30% Hb A, was converted to globin and fractionated by chromatography on CM-cellulose in 8 M urea at *p*H 6·8 (ref. 4). Two major basic α-chain components were observed in addition to the α(A) chain from the contaminating Hb A. Compared with the elution pattern from a sample made from impure Hb CS it was obvious that the minor α-chain components of Hb Icaria were relatively more basic than those of Hb CS, reflecting the differences seen on starch-gel electrophoresis. The abnormal α-chain fractions were combined and recovered by dialysis against 0·5% HCOOH and freeze drying, and then digested with trypsin. Peptide maps of the digest were prepared by high-voltage electrophoresis at *p*H 4·7, followed by chromatography in *n*-butanol:acetic acid:water:pyridine (15:3:12:10 by volume) (ref. 4). A digest of authentic α(CS) chain was also run as a control. Comparison of the two (Fig. 2) revealed that all the normal α(A)-chain peptides were present and that of the three major peptides unique to the α(CS)-chain[3], peptides Y and W$_I$ (that is, those representing residues 154 to 172) were present on the α(Icaria)-chain chromatogram, and had compositions identical to the equivalent peptides eluted from the α(CS)-chain peptide map. The remaining peptide X′ (X in the α(CS)-chain digest, corresponding to residues 142 to 153) was displaced on the α(Icaria)-chain peptide map, being slightly more cathodal on electrophoresis and faster in chromatography. In addition, two new spots, U and V, were observed in the α(Icaria)-chain digest. V had the same mobility in electrophoresis as α3 but was slower in chromatography, while U was slightly slower in electrophoresis than the free lysine (α8). It was also observed that α2, which normally gives a brown/grey colour with ninhydrin, was stained blue.

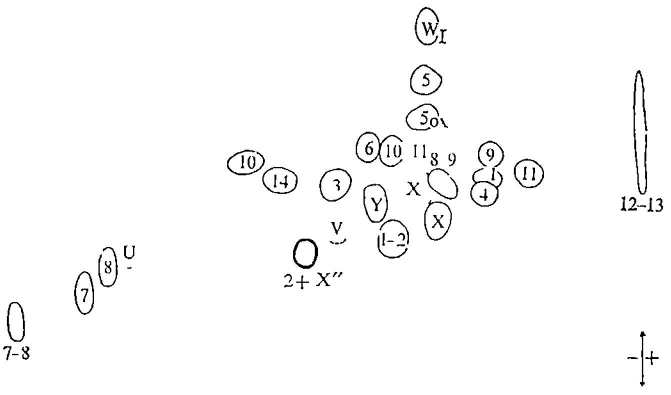

Fig. 2 Superimposed tracings of peptide maps of α(CS) and α(Icaria). Peptides common to both α chains are drawn in solid lines, those unique to α(Icaria) are dotted.

Peptides X′, V, U and 'α2' were cut out and the paper pieces washed with acetone before the peptides were eluted with 6 N HCl. One tenth of each sample was removed, dried and reacted with dansyl chloride for determination of the N-terminal residue[5] and the remainder was hydrolysed for 16 h for amino acid analysis. The results are summarised in Table 1.

X′ has a composition similar to α(CS)X, except for the absence of the glutamine N-terminal residue and the presence of N-terminal alanine. Peptide U, which has N-terminal tyrosine, has the composition of α(A)14 (Tyr, Arg) plus an additional lysine residue. 'α2' is obviously a mixture of genuine α2 (Thr, Asn, Val, Lys), and a peptide(X″) of composition Ser, Pro_2, Gly, Ala_4, Val_2, Arg, Lys, that is, X′+N-terminal lysine. These data are consistent with a sequence ... Tyr-Arg-Lys-Ala ... for residues 140–143 (Table 1) instead of the ... Tyr-Arg-Gln-Ala ... characteristic of all the examples of Hb CS yet studied[2,3] (Hb CS is found occasionally in Greece and was originally called Hb Athens[2]; we have redetermined the structure of Hb Athens and confirmed that its structure is identical with Hb CS.) Furthermore, peptide V has a composition and N-terminal residue consistent with the sequence of residues 142 to 147 (Table 1). In view of the extensive degradation of some of the finally purified samples of Hb Icaria, it seems likely that this represents a truncated version of the α(Icaria) chain, comparable to the CS2 and CS3 derivatives[3] of Hb CS which are thought to be produced by proteolysis during purification of the haemoglobin.

There is now good evidence that human α mRNA has a stretch of at least 100 nucleotides between the chain-termination codon and the poly(A) tract at the 3′-end[3] From a comparison of the amino acid sequences of Hb Constant Spring[3] and Hb Wayne[6] (a frame-shift mutant with an elongated α chain of 146 residues) a unique sequence of 26 nucleotides for codons 140–148 can be deduced for α-chain mRNA in which the normal chain-termination codon at position 142 is UAA (Fig 3) A single base substitution in this codon to CAA (Gln) or AAA (Lys) can thus account for the formation of elongated α-chain variants like Constant Spring and Icaria, translation continues beyond codon 141 until the first in-phase termination codon is reached, presumably at position 173

Hbs CS and Icaria are both present in extremely low amounts, of the order of 0 5 to 1%, in the red cells of heterozygotes In the case of Hb CS, biosynthetic experiments have shown that this is unlikely to be due to a translational defect (such as a rate-limiting step at the glutamine-142 codon) during assembly

Fig. 3 Partial amino acid and nucleotide sequences for α chains of haemoglobins A, CS, Icaria and Wayne The base sequences for codons 138 and 139 have been chosen arbitrarily Deletion of any one of the four bases before codon 140 produces the nucleotide sequence which defines the amino acid sequence at the C-terminal end of the α chain of Hb Wayne In this diagram the third base of the codon for Ser 138 has been deleted, the base sequence of the α mRNA is thus uniquely defined from codon 140 to the second base of codon 148

of the α(CS) chain[3] Rather the evidence suggests that α(CS) mRNA may be much more unstable than normal α(A)mRNA since its activity in the cell cytoplasm seems to be dependent on continued nuclear mRNA synthesis (to be published)

Laux *et al* have recently demonstrated the potential existence of a large base-paired loop, which includes the chain-termination codon, in human α mRNA[7] In phage and ribosomal RNAs such double stranded regions are thought to contribute to the overall stability of the RNA molecules[8,9] Hbs CS, Wayne and Icaria are all produced in very low amounts and are exceptional in that they share the property that they arise by the translation of stretches of mRNA that normally remain untranslated If these regions of the mRNA are essential for its stability or functional integrity, then their unfolding during translation may render the α mRNA more susceptible to degradation by nuclease attack, thus leading to low levels of functional mRNA

There is now strong genetic and biosynthetic evidence that the Hb CS mutation results in an overall deficit of α chains in affected red cells[10], and that its interaction with the severe α-thalassaemia gene (α-thal$_1$) causes about half the cases of Hb-H disease in south-east Asia[2,11] Preliminary studies indicate that Hb Icaria also produces a disorder similar to α thalassaemia The discovery of a further chain-termination variant causing α thalassaemia suggests that inefficiently synthesised Hb variants of this type may account for other forms of thalassaemia Obviously the blood of all thalassaemic patients should be screened carefully for trace amounts of haemoglobin variants

Measurements of unwinding of *lac* operator by repressor

We report here measurements of the rates of association and dissociation of the *lac* repressor and covalently closed λp*lac* DNAs of various degrees of superhelicity, from which we deduce that the binding of repressor unwinds the *lac* operator by 40° to 90° This small unwinding angle is inconsistent with binding mechanisms involving considerable disruption of DNA base-pairs and, in particular, with the model first proposed by Gierer[1] for specific repressor–operator interactions Our measurements were prompted by the existence of a twofold symmetry in the base sequence of the *lac* operator, which is a prerequisite of the Gierer model The minimal base sequence of the *lac* operator determined by Gilbert and Maxam[2], is depicted in Fig 1 as a regular double helix (Fig 1*a*), and as a Gierer-type structure (Fig 1*b*) According to Gierer's model, the *lac* repressor interacts specifically with the hairpinned structure shown in Fig 1*b*

Fig 1 *a*, The minimal base sequence of the *lac* operator taken from ref 2 The boxed regions are the symmetrical hexameric sequences which form the hydrogen-bonded regions of the two stems shown in *b*

The conversion of the *lac* operator from the structure shown in Fig 1*a* to the one shown in Fig 1*b* reduces the number of helical turns between the two complementary strands by approximately two full turns If the twofold symmetry in base sequence extends beyond the published sequence for the operator[2], the short stems shown in Fig 1*b* could be lengthened further, with an even greater reduction in the number of helical turns between the complementary strands For a negatively superhelical DNA, a reduction in the number of helical turns between the complementary strands, which decreases the absolute number of superhelical turns, is favoured thermodynamically[3] Thus for the binding of the *lac* repressor to two otherwise identical DNAs containing the operator, but with only one of the two DNAs containing negative superhelical turns, a direct prediction from the Gierer model is that the affinity of the repressor to the negatively superhelical DNA should be orders of magnitude higher than that to the DNA without superhelical turns[4] Maniatis and Ptashne[5] have used this approach to study the binding of the λ repressor to its operators, and have concluded that it is highly unlikely that the λ operators form some structure other than a linear duplex

Techniques have been developed for studying the specific interaction between the *lac* repressor and operator[6,7] The binding constant can be obtained from either equilibrium[6] or kinetic measurements[7,8] The high precision of the kinetic method makes it the method of choice in determining whether the binding of the *lac* repressor significantly unwinds the operator

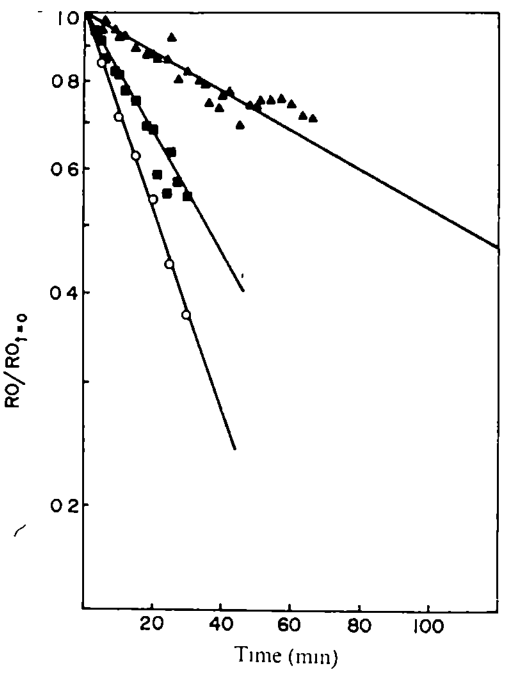

Fig 2 Rates of dissociation of repressor–operator complexes formed with operator DNAs with various degrees of superhelicity. The *lac* repressor was isolated from an *E. coli* strain, BMH461 (ref. 9), carrying a mutation (i^q), which leads to overproduction of the repressor. The purification procedure (to be published elsewhere), which includes DNA-cellulose chromatography, yields consistently, very pure and active repressor. The DNA was extracted from the λp*lac*5 phage purified from a low-thymine-requiring lysogenic strain MBC5 ((*lac pro*$_{AB}$) $\Delta_{XIII}T^-B^-_1$ nal$_A$R (λ $C_{1857}S_7$ p*lac*5 $i^-o^+z^+y^-$)) after growth in the presence of ^{3}H or ^{14}C-labelled thymine. The cyclisation and the covalent closure of the DNA in the presence of various amounts of ethidium bromide were done according to published procedures[10]. The purified covalently closed DNA samples were used within a few days. Fifty per cent of the DNA molecules of a ^{3}H-labelled sample with a specific activity of 2×10^5 c.p.m. μg^{-1} for example, were spontaneously converted to the nicked form by radiolysis in about 2 weeks. The membrane filter assay for repressor–operator complexes (RO) was used to titrate the repressor solution[6] as well as to measure the kinetic constants[7,8] of the repressor–operator interaction. The binding buffer used for all assays contained 0.01 M Tris buffer, *p*H 7.4, 0.01 M MgCl$_2$, 0.01 M KCl, 0.0001 M EDTA, 0.0001 M dithiothreitol, 5% dimethylsulphoxide and 25 μg bovine serum albumin per ml, which had been heated at 60° C for 30 min in 0.01 M Tris, *p*H 9, and then neturalised. The filtering buffer had the same composition as the binding buffer but without the bovine serum albumin and dimethylsulphoxide. The purified repressor and the bovine serum albumin were shown to contain negligible amounts of nuclease activity. Concentrations of DNA of from 0.6 to 3×10^{-12} M operator were used in dissociation kinetic experiments, depending on the specific activity of the DNA preparation. The halflife of repressor–operator complexes is, however, independent of concentration[7]. A fourfold excess of repressor over operator was added to the DNA in the binding buffer and the repressor–operator complexes were allowed to form during a 30-min incubation at room temperature. The dissociation reaction was initiated by addition of unlabelled operator DNA (linear λφ80 d*lac* DNA) in a 100-fold excess over the labelled operator DNA concentration, and three 0.5 ml samples were filtered on HA Millipore filters, at appropriate times. The filters were washed once with 0.5 ml of filtering buffer, dried, and counted in a scintillation counter. The values obtained for the c.p.m. retained on triplicate filters were averaged. A background value of the amount of radioactivity retained on the filters in the presence of 10^{-3} M isopropyl-β-D-thiogalactoside, an inducer of the *lac* operon, was measured in each experiment and subtracted. The data are presented as the fraction of the amount of repressor–operator complex (RO) present before the addition of the unlabelled operator DNA. The data shown represent averaged values obtained in several independent experiments for each DNA. The initial slopes of the RO complex decay curves were calculated by least-square fitting of the data. ○, $\sigma = -0.001$, average of four experiments $t_{1/2} = 22$ min; ■, $\sigma = -0.017$, average of four experiments $t_{1/2} = 35$ min; ▲, $\sigma = -0.035$, average of five experiments $t_{1/2} = 105$ min.

The rates of dissociation (k_b) and association (k_a) have been measured for the binding of the *lac* repressor to five covalently closed circular λp*lac* DNA samples with superhelical densities σ (defined as the number of superhelical turns per ten base pairs[3] and based on an unwinding angle of 12° for ethidium) −0.001, −0.017, −0.028, −0.035 and −0.049 (or 5, 80, 160 and 230 negative superhelical turns respectively) under the binding conditions. Figure 2 illustrates the results for the rate of dissociation of the repressor from operator DNAs with −5, −80 and −160 superhelical turns. The negative superhelical turns of the DNA clearly stabilise the repressor–operator complex. The halflife of the complex is 22 min for the essentially untwisted DNA (−5 superhelical turns) and 105 min for the DNA with −160 superhelical turns. Results obtained for all DNA samples are summarised in Table 1.

Measurements of k_a are somewhat less accurate. Representative data are illustrated in Fig. 3. A small increase is observed with increasing negative superhelicity. Results obtained for all DNA samples are presented in Table 1.

Table 1 Affinity of the *lac* repressor for operator DNAs with various degrees of superhelicity

σ	$t_{1/2}$ (min)	$k_b \times 10^4$ (s^{-1})	$k_a \times 10^9$ (mol^{-1}s^{-1})	$K_a \times 10^{-13}$ (mol^{-1})	K_a^σ/K_a	θ (degrees)
Linear	25	4.7 ± 0.3	2.4 ± 0.5	0.5		
−0.001	22	5.4 ± 0.2	3.4 ± 0.6	0.6		
−0.017	35	3.3 ± 0.2	5.7 ± 0.5	1.7	2.8	43
−0.028	65	1.8 ± 0.3	4.4 ± 1.1	2.5	3.9	35
−0.035	105	1.1 ± 0.3	9.2 ± 1.0	8.5	13.6	53
−0.049	78	1.5 ± 0.1	7.5 ± 1.0	5.1	8.7	31

The halflives ($t_{1/2}$) of the different repressor–operator complexes were measured as described in the legend to Fig. 2. The rate constant of dissociation (k_b) is related to $t_{1/2}$ by the relationship $k_b = 1.17 \times 10^{-2}/t_{1/2}$, where $t_{1/2}$ is expressed in min. The rate constants of association (k_a) of the repressor to the different operator DNAs were measured as described in the legend to Fig. 3. The values shown represent the mean value of N experiments and the errors were calculated as $E = 1/N\sqrt{\Sigma (X-\bar{X})^2}$ where $X-\bar{X}$ is the deviation from the mean for each experiment. In general $N = 4$ except in the cases of the measurement of k_b with the DNA of $\sigma = -0.035$ ($N = 5$) and of k_a with the DNA of $\sigma = -0.035$ ($N = 5$) and of k_a with the DNAs of $\sigma = -0.017$ ($N = 2$), $\sigma = -0.035$ and $\sigma = -0.049$ ($N = 3$). The uncoiling angle of θ of the DNA helix due to the binding of a *lac* repressor is calculated from the equation[1]

$$K^\sigma_a/K_a = \exp(-1/RT\ (dG_\tau/d\tau)\ (\theta/360)),$$

where K^σ_a and K_a are the equilibrium constants for the binding of the repressor to DNAs with superhelical densities σ and *o* respectively, and $dG_\tau/d\tau$ is the free energy change per unit change in τ, the number of superhelical turns. The recent unpublished results of Hsieh and Wang, $dG_\tau/d\tau = 505\,RT\sigma$, were used in the calculation of θ. Previously Bauer and Vinograd[1] gave $dG_\tau/d\tau = RT\,(844\,\sigma - 2640\,\sigma^2)$. If the results of Bauer and Vinograd are used, the calculated θ values are lowered by approximately a factor of 1.5.

The affinity of the repressor for the operator, $K_a = k_a/k_b$, increases with increasing negative superhelicity up to a factor of approximately 14 for the DNA with −160 superhelical turns. Its affinity for the highly superhelical DNA with −230 turns is somewhat lower than for the DNA with −160 turns. The reason for this decrease is not clear. It has been observed[12] that for highly twisted PM2 DNAs with a negative superhelical density greater than ~0.045, the template activity of the DNA for transcription by *E. coli* RNA polymerase also decreases with increasing negative superhelicity. It is plausible that for such highly twisted DNAs, in addition to the free energy of superhelix formation[3], other factors such as steric hindrance, change of hydration of the DNA helix, and structural distortion of the helix[13] are also affecting the interactions between the DNA and other macromolecules.

From the dependence of the equilibrium constant K_a on σ, the unwinding angle θ of the *lac* operator due to the binding of a repressor can be calculated from the free energy of superhelix formation[4] The values are tabulated in the last column of Table 1 On the binding of a *lac* repressor, the operator unwinds by about 40°, or approximately one tenth of a helical turn This small unwinding cannot be reconciled with the prediction of the Gierer model for the operator structure shown in Fig 1*b*, unless the operator exists as the hairpinned structure in the absence as well as in the presence of repressor The melting temperature of the operator fragment[2] indicates, however, that it is highly unlikely that the operator assumes the hairpinned structure in the absence of repressor

We also tried to measure the unwinding of the *lac* operator by the method of Saucier and Wang[14] No definitive conclusion was obtained by this technique, which is not unexpected since the estimated value for θ is approximately the limit of detection of this technique

Maniatis and Ptashne[5] have shown, by measuring the amounts of λ repressor bound at equilibrium to linear and superhelical λ DNAs, that virtually no unwinding of the λ operator occurs on binding of the λ repressor The observed difference in affinity for the two DNAs was less than a factor of two For superhelical λ DNA isolated from infected cells, which was used in their measurements, σ is expected to be in the range of 0 026 to 0 031 (ref 15) If λ repressor unwinds the λ operator to the same extent as in the case of the *lac* system, the difference in affinities for the superhelical and linear λ DNA samples used would be approximately a factor of 4 (Table 1) It therefore appears that λ repressor does not unwind the λ operator as much as the *lac* repressor unwinds its operator, if at all

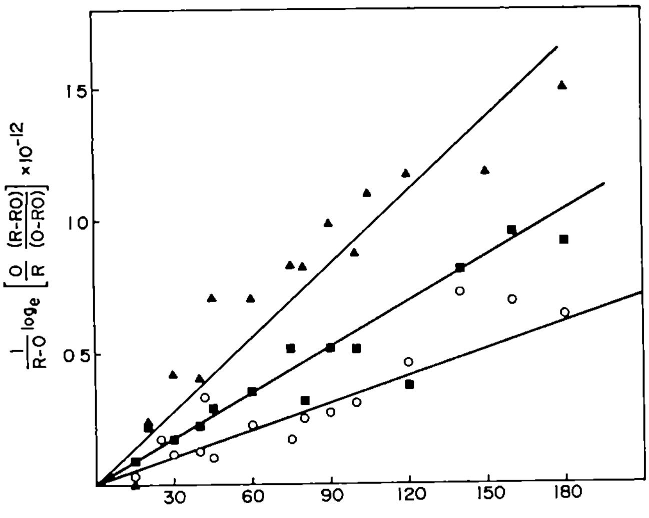

Fig 3 Rates of association of the repressor to operator DNAs with various degrees of superhelicity The conditions of the binding assay are the same as described in the legend of Fig 2 except that the concentrations of the operator DNA varied from 0 4 to 1 × 10^{-12} M and that only a twofold excess of repressor was used The total operator and repressor concentrations were determined precisely and the concentration of the repressor operator complex (RO) was calculated using a conversion factor estimated by filtering a known amount of RO complex under the same experimental conditions[7] The reaction was initiated by mixing the repressor and the operator DNA and the association was stopped at appropriate times by transferring 1 5 ml samples into 100 μl of a mixture containing 4 μg of unlabelled λΦ80 d*lac* DNA and 10^{-2} M *o*-nitrophenyl-β-D-fucoside The presence of about 100-fold excess of unlabelled operator DNA prevents the formation of new labelled RO complexes while the anti-inducer, *o*-nitrophenyl-β-D-fucoside, stabilises the existing labelled RO complexes[11] Three 0 5-ml samples of that mixture were filtered, washed and counted and the triplicate values were averaged, as described earlier The background value of the amount of radioactivity retained on the filters in the presence of 10^{-3}M isoprophyl-β-D-thiogalactoside was subtracted from each time point The data were plotted according to the rate equation for a bimolecular reaction[7], with R and O denoting the total repressor and operator concentrations respectively The rate constant of association, k_a, was obtained from the slope of the least-square line ○, $\sigma = -0\ 001$, average of four experiments, $k_a = 3\ 4 \times 10^9$ mol^{-1} s^{-1}, ■, $\sigma = -0\ 017$, average of two experiments, $k_a = 5\ 7 \times 10^9$ mol^{-1} s^{-1}, ▲, $\sigma = -0\ 035$, average of three experiments, $k_a = 9\ 2 \times 10^9$ mol^{-1} s^{-1}

In the calculation of θ from the free energy of superhelix formation, it has been implicitly assumed that the intercalative dye ethidium unwinds the DNA helix by 12° Recent results of one of us (J C W) indicate that the unwinding angle for ethidium is likely to be significantly larger than 12° with 26° being the best estimate This would lead to a proportionately larger value for θ of about 90° Since the size of the *lac* operator is about 30 base pairs, an unwinding of 40° to 90° suggests a significant change of the operator structure on the binding of the *lac* repressor

Thus the conclusions of our unwinding measurements are twofold On one hand, our results suggest that the recognition of the operator by the *lac* repressor is primarily through interactions with groups of the bases in the groves Recognition either by the Gierer model or by the disruption of a segment of the base pairs, thus exposing a sufficient number of bases, is inconsistent with our results On the other hand, the specific interaction between the operator and the repressor involves a structural change of the operator, as evidenced by the unwinding measured This structural change is likely to be important in recognition

Subunit structure of chromatin

IN the past, the structure of chromatin has remained obscure despite the efforts of many laboratories and seemed far from a simple solution[1] It has been known only that chromatin contains a repeating substructure[2 3] Recently, however, Kornberg proposed[4] that chromatin structure is based on a repeating subunit of 200 base pairs of DNA and two of each of the histones (with the exception of F1 which occurs only once per subunit). Furthermore, he suggested that in chromatin these subunits form a flexibly jointed chain.

Here I present evidence in favour of this model. It is shown that 85% of chromatin can be converted to a subunit by digestion with micrococcal nuclease. This subunit contains about 205 base pairs of DNA and occurs as a discrete complex in solution. As well as demonstrating the existence of a chromatin subunit, the methods described here provide a means of isolating the subunit on a preparative scale and represent a test for the native state of chromatin.

Previous work has shown that a considerable amount of the DNA in rat liver nuclei is cleaved to integral multiples of a unit length upon digestion by an endogenous Ca^{2+} and Mg^{2+}-dependent endonuclease[3]. I have confirmed this result using the enzyme purified from rat liver nuclei, and demonstrated that the same DNA fragments are obtained after digestion with micrococcal nuclease (Fig 1). A similar result is obtained with DNase I although the pattern is obscured by a very high background. Whereas both the rat liver enzyme and micrococcal nuclease require Ca^{2+}, DNase I requires only Mg^{2+}. Thus, the occurrence of regularly spaced cleavage sites is not dependent on the presence of a specific divalent cation.

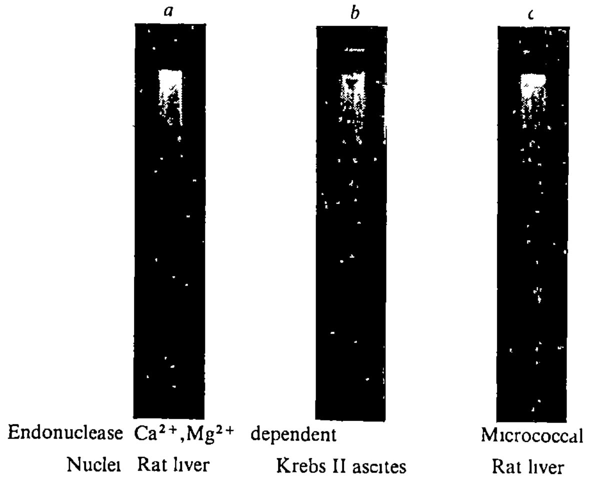

Fig 1 Polyacrylamide gel analysis of DNA digested *in situ* with micrococcal nuclease or Ca^{2+}, Mg^{2+} dependent endonuclease. *a*, Rat liver nuclei containing the Ca^{2+}, Mg^{2+} dependent endonuclease were incubated at 1.5×10^8 nuclei ml^{-1} as described[3] in the presence of 10 mM $MgCl_2$ and 1 mM $CaCl_2$ for 60 min at 37° C. *b*, Krebs II ascites nuclei which lack the Ca^{2+}, Mg^{2+} dependent endonuclease[6] were incubated as in (*a*) in the presence of 0.5 units ml^{-1} of purified Ca^{2+}, Mg^{2+} dependent endonuclease (M. N., to be published). *c*, Incubation of rat liver nuclei with 300 units ml^{-1} of micrococcal nuclease (Worthington Biochemical Co.) in 1 mM $CaCl_2$ for 15 s at 37° C. After incubation the DNA was extracted, precipitated and analysed on 2.5% acrylamide gels essentially as described[3,6].

Having established that readily available nucleases produce the same digestion pattern as the Ca^{2+}, Mg^{2+} dependent endonuclease, it was possible to answer many questions concerning the hypothetical chromatin subunit. For example, the proportion of chromatin based on this subunit structure could be determined. For this purpose it was necessary to determine the proportion of DNA that can be broken down into monomers (DNA of unit length associated with the hypothetical chromatin subunit of which the sizes of the larger DNA fragments [dimers, trimers, and so on] are integral multiples) or resolved multiples thereof if it is digested *in situ* with saturating amounts of the micrococcal enzyme. It is evident from Fig 2 that nearly all DNA is converted to the monomer size. In addition to the analysis of the DNA fragments on gels, the amount of TCA soluble DNA had to be taken into account in order to obtain a reliable value for the proportion of chromatin consisting of the repeating subunit. Under conditions converting all the DNA on the gel to monomers and resolved multiples of it (Fig 2*a*), 13% of the DNA was acid soluble. This shows that at least 87% of the chromatin consists of the subunit, since the background of DNA between the bands is extremely low (as judged by its evaluation between the well separated first three bands). This estimate represents only a lower limit since some of the TCA soluble DNA is probably due to partial degradation of DNA in the substructure as indicated by the finding that further digestion produced more acid soluble DNA (28% in Fig 2*c*).

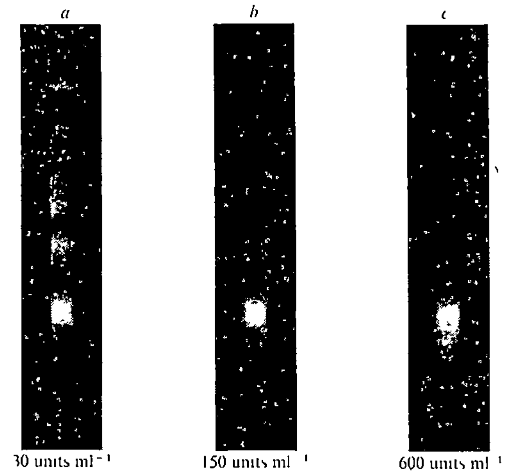

Fig 2 Titration of chromatin digestion with micrococcal nuclease. Rat liver nuclei were incubated for 6 min at 37° C in a standard reaction mixture as described for Fig 1*c* with increasing concentrations of micrococcal nuclease. *a*, 30 units ml^{-1}, *b*, 150 units ml^{-1}, and *c*, 600 units ml^{-1}. Incubation mixtures were processed and analysed as described in the legend of Fig 1.

It is evident from Fig 2 that increasing digestion with micrococcal nuclease is accompanied by the appearance of fragments smaller than the monomer which might arise by cleavage at a few sites located within the subunit. After relatively mild digestion, on the other hand, the monomer can be observed to consist of a doublet (Fig 3). Increasing digestion shifts the relative intensities of the two bands in favour of the lower band which suggests that it is produced from the upper band. Thus it is conceivable that the upper band is the true monomer while the lower band arises by cleavage at a preferred internal site of the monomer.

To clarify the relationship between the monomer doublet and the higher DNA bands an accurate determination of their size and breadth is required. This was achieved by calibration with a series of sequenced DNA fragments generously supplied by Dr J. W. Sedat. Thus the DNA of a micrococcal nuclease digest, the Hin fragments and a set of sequenced single-stranded Endo IV products of ΦX174 were run in parallel on a 99% formamide slab gel (not shown). From the sharpness of the Hin fragment bands it was apparent that no partial renaturation occurred on the gel. A logarithmic plot of the molecular weight of the Hin (P. G. N. Jeppesen, personal communication) and Endo IV (ref. 5 and unpublished results of J. W. Sedat and F. Sanger) products (the lengths of the Hin fragments had been determined by EM and did not deviate from their true value by more than 10% as judged by comparison with the sequenced Endo IV products) as a function of the square root of their mobility, resulted in a smooth calibration curve which was linear in the range of 200–400 bases. From comparison with this calibration curve the following values were obtained for the monomer doublet, dimer and trimer monomer doublet=205±15 base pairs and 170±10 base pairs, dimer=405±35 base pairs, trimer=605±40 base pairs (The breadth of the bands reflects true heterogeneity in size rather than diffusion in the gel—see also ref 6) The sizes of the monomer bands are consistent with an estimate of the average molecular weight of monomer DNA from sedimentation analysis on sucrose gradients[6]

The measurements clearly show that no multiples of the lower monomer band are found and strongly suggest that both dimer and trimer correspond to twice and three times the length of the upper monomer band rather than a linear combination of both monomer bands The data, therefore, favour a model in which the monomer doublet consists of the real monomer (205 base pairs) and a degradation product of it (170 base pairs) produced by cleavage at a site located approximately 20% within the monomer No 'monomers', however, are observed arising from cleavage at this site in the dimer, that is, the monomer has never been observed as a triplet (with a third band of 240 base pairs) A possible explanation would be that the internal cleavage site only becomes accessible in the free subunit

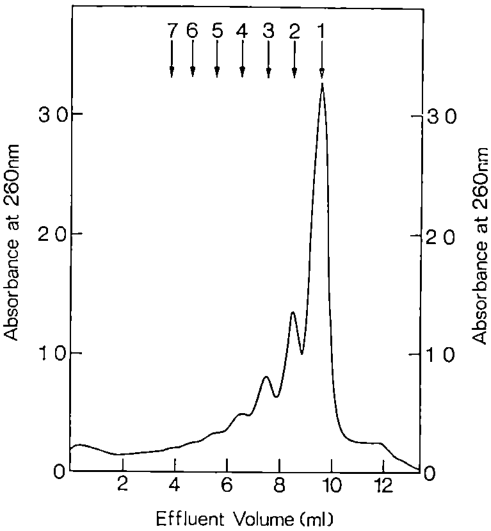

Fig 4 Sucrose gradient analysis of digested chromatin Digested chromatin was prepared from rat liver nuclei as described for Fig 3 except that incubation was for 2 min rather than 15 s The chromatin supernatant (5 5 A_{260} units) was layered on a 11 5-ml isokinetic sucrose gradient (D Calhoun, M N and H Noll, in preparation) with $c_t=5\%$, $c_r=28\ 8\%$, and $V_m=55\ 5$ ml in 0 2 mM EDTA, *p*H 7 and centrifuged for 12 75 h at 28,000 r p m and 4° C in a Beckman SW40 rotor The gradient was monitored for absorbancy by passing the effluent from the bottom of the tube through a turbulence free flow cell (Molecular Instruments Co , PO Box 1652, Evanston, Illinois 60201, USA)

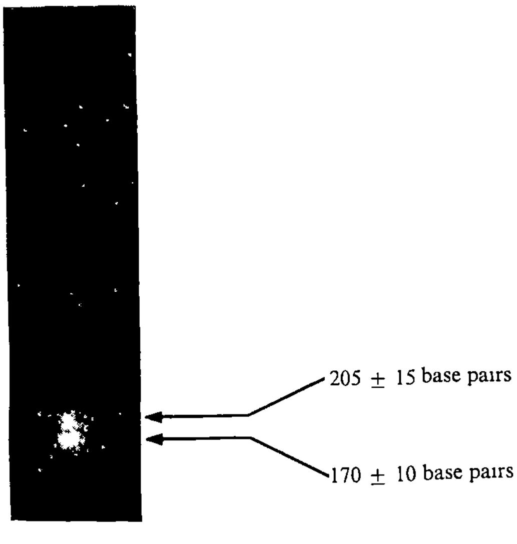

Fig 3 Monomer doublet after 'mild' micrococcal nuclease digestion After incubation of rat liver nuclei with micrococcal nuclease (15 s at 37° C, 150 units ml^{-1}) the nuclei were pelleted at low speed, resuspended in 0 2 mM EDTA, and homogenised with a Waring blender The homogenate was centrifuged for 30 min at 12,000*g* and the supernatant containing the digested chromatin was processed and analysed as described for Fig 1

The results presented so far concern primarily the composition of the chromatin subunit Evidence that the subunit occurs as a discrete complex in solution comes from sucrose gradient analysis of chromatin previously digested with micrococcal nuclease As demonstrated in Fig 4 a regular series of seven resolved peaks is observed which have been shown to contain DNA of the size of the monomer (first peak), dimer (second peak), trimer (third peak) and so on Thus histone–histone interaction between adjacent subunits is not sufficient to hold them together Since the sucrose gradient is isokinetic (for a particle density of 1 5 g cm^{-3}) the S-values are proportional to the distance migrated in the gradient[7] By calibration with 30S ribosomal subunits of *Escherichia coli*[8] it was shown that the chromatin subunits sediment at 11 2±0 4S and the chromatin dimers at 15 9±0 5S These values have been confirmed by sedimentation velocity analysis in an analytical ultracentrifuge The first two peak fractions when fixed with formaldehyde band both as a homogenous peak with a buoyant density of 1 45 g cm^{-3} in a CsCl gradient, exhibit a protein to DNA ratio of approximately 1 3 and contain in addition to all five major histones some non-histone proteins Van Holde and coworkers have reported a 12S product of micrococcal nuclease digested chromatin[9] The 12S material differs from the 11S subunit reported here in size of DNA (about 100 rather than 205 base pairs) and protein to DNA ratio (1 5 rather than 1 3) The 12S material may arise from the 11S subunit through over-digestion (ref 4, footnote 8)

I thank Drs R D Kornberg, F H C Crick and J D Smith for discussions and criticism and Drs J W Sedat and P G N Jeppesen for Endo IV and Hin fragments This work has been supported by a long term fellowship from EMBO

Protein synthesis and the release of the replicated chromosome from the cell membrane

In *Escherichia coli*, chromosome replication must be followed by a short period of protein synthesis for subsequent division of the cell[1] The protein synthesised during this period has been termed 'termination protein'[1,2] We have set out to test the hypothesis[2] that this post-replication protein synthesis is required to release the chromosomal DNA from its attachment to the cell membrane and that this detachment is necessary for subsequent cell division The results of the experiments reported here provide support for this model

A recently-described technique permits the isolation of the chromosome of *E coli* as a highly folded condensed structure complexed with small amounts of RNA and protein[3] Both the RNA and the protein (which is largely RNA polymerase) are required for maintaining the chromosome or 'nucleoid' in its condensed state[4,5] It has been hypothesised that this folded form is the normal state of the chromosome within the intact cell When a modified extraction procedure is used, the folded chromosome can be isolated attached to fragments of the cell membrane[4,6] According to Worcel and Burgi[6], the chromosome becomes detached from the membrane when replication is completed in the absence of a required amino acid, but becomes re-attached some time after the addition of the amino acid They therefore conclude that the chromosome is attached to the membrane during replication and is released after the completion of replication We describe here experiments which confirm these findings and also show that protein synthesis is required for the release of the replicated chromosome from the cell membrane

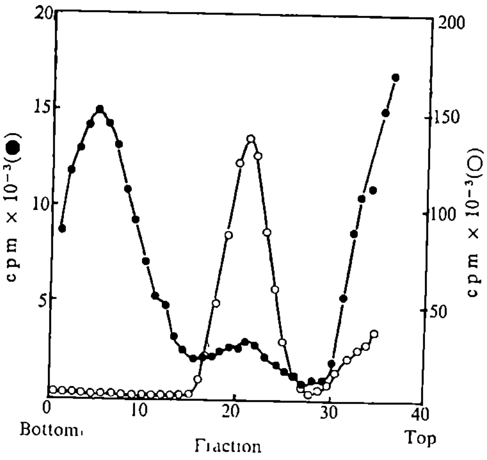

Fig 1 Sucrose gradient profiles of cell lysates prepared at 0° C and at 25° C ^{3}H-thymidine (0 5 μCi ml^{-1}, 90 4 mCi mg^{-1}) was added to an exponential culture of *E coli* Km7T$^-$ growing at 37° C in 007-glucose minimal medium[1] supplemented with threonine (50 μg ml^{-1}), leucine (50 μg ml^{-1}), thiamine (10 μg ml^{-1}) and thymine (10 μg ml^{-1}) Growth was continued for 60 min and then the cells were rapidly harvested and lysed essentially as described by Stonington and Pettijohn[3] The cells were harvested by centrifugation and the pellet (2–3 × 10^9 cells) resuspended at 0° C in 0 4 ml of a solution containing 0 01 M Tris (*p*H 8 1), 0 01 M sodium azide, 0 1 M sodium chloride, 20% sucrose (w/v) and 0 01% diethyl-pyrocarbonate (added separately for each experiment) Aliquots (0 1 ml) of a 30 mg ml^{-1} solution of lysozyme in 0 12 M Tris (*p*H 8 1) and 0 05 M EDTA were immediately added and 30 s later 0 5 ml of a lysis solution containing 1% Brij-58, 0 4% deoxycholate, 2 M sodium chloride, 0 01 M EDTA (*p*H 8 1) was added Lysis was allowed to continue at 0° C or 25° C for 10 min The lysate was spun at 4,000*g* at 0° C for 5 min and the supernatant layered on to a 5 ml 10–30% (w/v) sucrose gradient containing 0 01 M Tris (*p*H 8 1), 1 M sodium chloride, 0 001 M EDTA and 0 001 M 2-mercaptoethanol The gradients were spun in a Beckman SW50 1 rotor for 20 min at 17,000 r p m and at 2–4° C Fractions were collected on Whatman 3MM filters and the filters washed in 10% TCA (2×) and acetone, dried and counted in a toluene based scintillation fluid ●, Cells lysed at 0° C, ○, cells lysed at 25° C

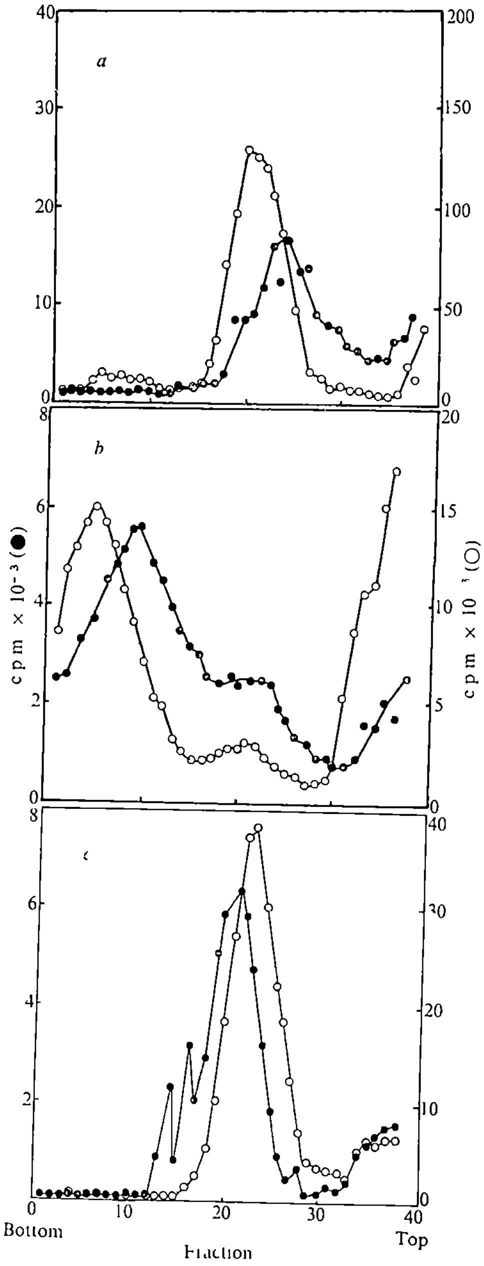

Fig 2 Detachment of nucleoids from the membrane ^{3}H-thymidine (0 5 μCi ml^{-1}, 90 4 mCi mg^{-1}) was added to an exponentially growing culture of *E coli* Km7T$^-$ in supplemented minimal medium (see Fig 1) After 60 min, cells were treated in one of three ways *a*, Cells were incubated for 60 min with rifampicin (500 μg ml^{-1}) and then washed on a membrane filter with prewarmed medium[1], after which they were resuspended in fresh medium and nucleoids prepared at 4° C 10 min later *b*, Cells were incubated in rifampicin and washed as in (*a*), but resuspended in medium containing chloramphenicol (160 μg ml^{-1}) before preparation of nucleoids at 0° C 10 min later *c*, Cells were incubated for 50 min with chloramphenicol (160 μg ml^{-1}) before preparation of nucleoids at 25° C ●, Nucleoids prepared from treated cells at 0° C (*a* and *b*) or 25° C (*c*) ○—○, Nucleoids prepared from exponentially growing cells at 0° C (*b*) or 25° C (*a* and *c*)

E coli Km7T$^-$ was used in these experiments In this strain RNA synthesis can be rapidly inhibited by the addition of rifampicin and then restarted by its removal[7] In the presence of rifampicin (as in the absence of required amino acids) chromosome replication completes but is not reinitiated[1] It was found necessary to use rifampicin rather than amino acid starvation because the latter allowed considerable turnover of protein[8–10] This turnover was found to be sufficient to allow the synthesis of termination protein (N C J, unpublished results)

Nucleoids were isolated from the cells by the procedure of Stonington and Pettijohn[3] We found the sedimentation of these bodies on sucrose gradients to be very similar to that described by other workers[4 6] When exponentially growing cells were lysed at 25° C all the DNA (prelabelled with ^{3}H-thymidine) was found in a broad, slowly sedimenting peak characteristic of membrane-free nucleoids (Fig 1) When the cells were lysed at 0° C, however, the DNA was found to be mainly in a fast sedimenting peak characteristic of membrane-bound nucleoids (Fig 1) In the cells lysed at 0° C, a minor fraction of the DNA sedimented at the rate expected for membrane-free nucleoids (as found also by others[6]) These may represent the chromosomes extracted from the cells which had completed their rounds of chromosome replication, as the proportion observed (about 17%) is close to the expected proportion of DNA which is in non-replicating chromosomes in an asynchronous exponential population with the observed generation time (about 60 min)[11]

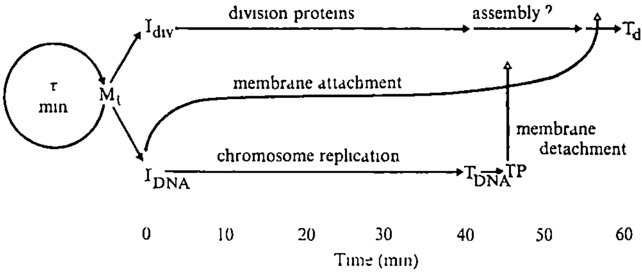

Fig 3 Model of the cell cycle in *E coli* (modified from Jones and Donachie[1], Fig 6) Doubling of the initiation mass (M_i[13]) takes place every mass doubling time (τ min) At each doubling chromosome replication (I_{DNA}) and synthesis of a set of division proteins (I_{DIV}) are initiated approximately simultaneously Completion of the synthesis of division proteins takes place at about 40 min and this in turn initiates a sequence of events (IA) which takes 20 min to complete, does not require the synthesis of DNA, RNA or protein and which leads to cell division Initiation of chromosome replication requires the attachment to a specific membrane site and this attachment prevents the completion of a terminal stage in the division sequence Termination of DNA replication (T_{DNA}) after 40 min however, induces the synthesis of termination protein (TP) which is required for the release of the replicated chromosomes from the membrane and, consequently, for eventual cell division

In agreement with other workers, it was found that folded chromosomes could not be isolated from cells treated with rifampicin[4] This is in accord with the idea that continuing RNA synthesis is necessary to maintain the nucleoid in its folded form The chromosomes are recovered in the folded form within 10 min or less of removing the rifampicin, however, even in the presence of chloramphenicol, and so only a small amount of new RNA synthesis and no new protein synthesis is needed for refolding of the chromosome

This enabled us to use the following procedure to test whether protein synthesis is needed for the dissociation of the chromosome from the membrane An exponential culture was treated with rifampicin for 60 min to allow completion of all rounds of chromosome replication The rifampicin was removed and RNA synthesis resumed for 10 min (to allow refolding of the chromosome) in the presence or absence of chloramphenicol Nucleoids were then prepared from these cells at 0° C If protein synthesis is necessary for detachment, then this detachment would be prevented by the chloramphenicol and so the nucleoids would remain membrane bound The results in Fig 2 show that this is indeed the case The nucleoids prepared from the cells that were allowed to resume RNA synthesis in the absence of chloramphenicol, sedimented at a position characteristic of membrane-free nucleoids (Fig 2*a*) When chloramphenicol was present, however, the nucleoids prepared were found to be membrane bound (Fig 2*b*) Fig 2*c* shows the sedimentation coefficients of nucleoids prepared from untreated exponentially growing cells and cells treated with chloramphenicol The results show that the chloramphenicol does cause a small increase in the sedimentation coefficient of the nucleoid[12] but this increase is not significant enough to account for the above results

The sedimentation peaks of both the membrane-bound and the membrane-free nucleoids were slightly displaced towards the top of the gradient by comparison with the corresponding membrane-bound and membrane-free nucleoids prepared from exponential cells This would be expected if chromosome replication were completed during the rifampicin treatment because the nucleoids should each consist of a single unreplicated chromosome while those from exponential populations should consist of chromosomes in all stages of replication and contain 1–2 chromosome equivalents of DNA[6]

A small fraction of the nucleoids from the cells to which chloramphenicol was added after the removal of rifampicin (Fig 2*b*) was membrane free This proportion was similar to the proportion of membrane-free nucleoids prepared at 0° C from exponential cells (Fig 1) The cells from which these were obtained had presumably completed replication before the addition of the rifampicin

The results reported here therefore confirm those of Worcel and Burgi[6] but in addition show that a short period of protein synthesis (10 min or less) after the completion of DNA replication is required for the release of the folded chromosome from the membrane We have shown previously that termination protein synthesis at this same time is a necessary prerequisite for subsequent division[1] It is therefore tempting to speculate that the role of termination protein is to release replicated chromosomes from their sites of membrane attachment and that therefore it is the attachment of the chromosome to a membrane site (at initiation of DNA replication) which sets up a block to cell division The subsequent release of this attachment, at termination of replication, would then abolish the block to division

Figure 3 represents our present model for the control of cell division in *E coli*, modified from that given earlier[1] to include the suggested role of termination protein

Sodium pump stoichiometry in *Aplysia* neurones from simultaneous current and tracer measurements

THERE is growing evidence for the involvement in neuronal performance of hyperpolarising current resulting from the activities of the membrane 'sodium pump'[1] Studies of the stoichiometry of metabolically fuelled ionic movements[1–6] have consistently shown that more Na is extruded than K accumulated But while the electrical effect of such an imbalance is of immediate significance to the ongoing activity of a neurone, we are aware of only one study in which the electrogenicity of sodium pump activity in a neurone has been estimated[7] Here we make such an estimate by comparing simultaneous measurements from a single neurone somata of tracer Na efflux and the transmembrane current attributable to that efflux The results show that at least half of the actively extruded Na is electrogenic

The experiments were carried out on the giant cell, 500–700 μm in diameter of the abdominal or pleural ganglions of *Aplysia californica*[8], iontophoretically injected with ^{24}Na The experimental arrangements are presented diagrammatically in Fig 1

Figure 2 shows the variations with time of the membrane potential [*E*m], pump current (*I*), intracellular Na activity ([Na]$_i$) and ^{24}Na efflux (φ) following two steps of constant and sustained injection of ^{24}Na As soon as the ^{24}Na injection was started by passing a 50 nA current between the two injection electrodes ($t=0$ in Fig 2) hyperpolarisation developed (lower curve in Fig 2) Concomitantly, a positive value of pump current was recorded After a small delay, partly due to dead space in the washout system, the efflux also increased Internal Na increased and, together with the other parameters recorded, reached a new equilibrium level after 45 min constant injection Observations such as these show that in these experiments a steady state was reached, in which Na efflux matched the injection rate When the injection was doubled, all parameters again rose and reached higher equilibrium values

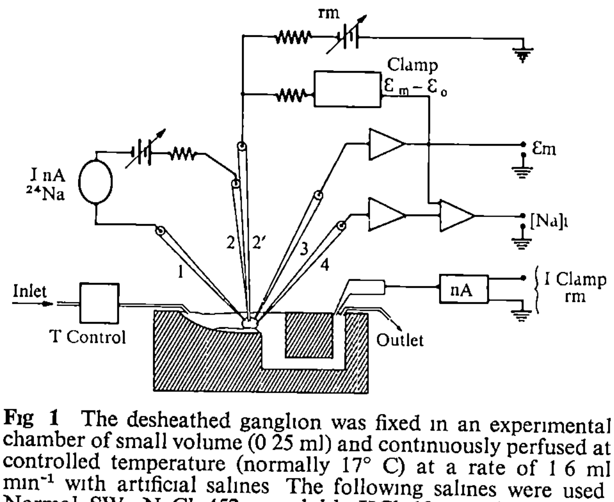

Fig 1 The desheathed ganglion was fixed in an experimental chamber of small volume (0 25 ml) and continuously perfused at controlled temperature (normally 17° C) at a rate of 1 6 ml min^{-1} with artificial salines The following salines were used Normal SW, NaCl, 452 mmol l^{-1}, KCl, 10 mmol l^{-1}, CaCl$_2$, 11 mmol l^{-1}, MgCl$_2$, 49 mmol l^{-1}, NaHCO$_3$, 6 mmol l^{-1}, K-free SW, same as normal SW minus KCl, Na-free (Tris) SW, Tris 513 mmol l^{-1}, KCl, 10 mmol l^{-1}, CaCl$_2$ 11 mmol l^{-1}, MgCl$_2$ 49 mmol l^{-1}, Na-free (Mg mannitol) SW, MgCl$_2$, 283 mmol l^{-1}, CaCl$_2$, 11 mmol l^{-1}, KHCO$_3$ 10 mmol l^{-1}, mannitol, 234 mmol l^{-1} Controlled amounts of Na were injected into the cells between electrode 1 (2 M ^{24}NaCl solution, 15 mCi mmol^{-1}) and electrode 2 (KCl) Every 3 min, a slow time-constant voltage clamp device reset the membrane potential, $\mathcal{E}_m$ (measured with a separate electrode 3), to the initial value, $\mathcal{E}_0$, for about 30 s by injecting a current across the membrane (electrode 2′) This current was considered equivalent to the additional pump current in response to the Na injection[7] Effluents were collected for 3 min periods and the ^{24}Na radioactivity counted In some experiments the intracellular Na activity was measured with an Na-sensitive microelectrode (electrode 4) according to Thomas' procedure[9]

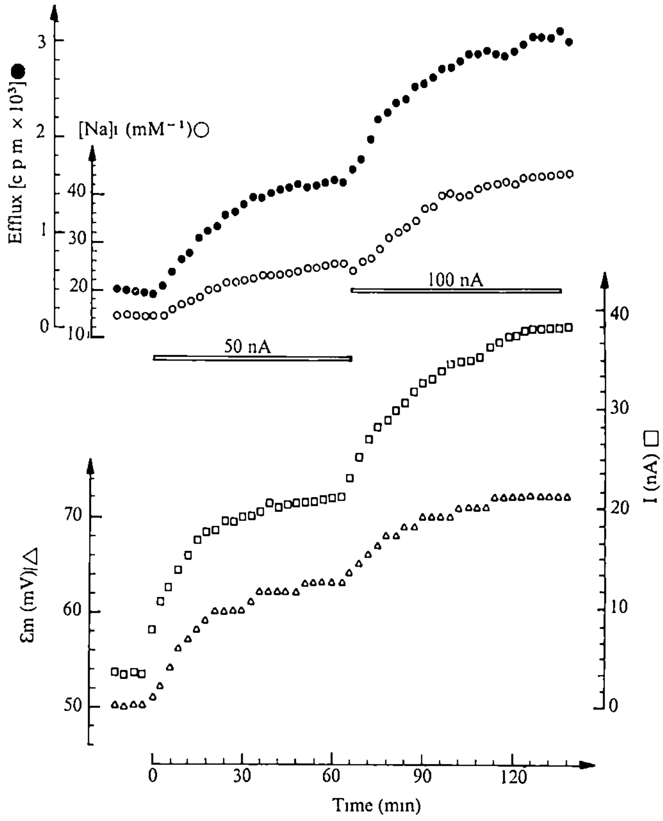

Fig 2 Time course of membrane potential (△), clamp current (□), intracellular Na activity (○) and efflux of ^{24}Na (●) from a giant cell following two steps of constant ^{24}Na injection Steady values are reached within 45 min of beginning a constant current ^{24}Na injection

We have used strophanthidin to define the fraction of the total ^{24}Na efflux which represents active extrusion The data are summarised in Table 1 When strophanthidin (10^{-3} M^{-1}) was added to the perfusing saline, ^{24}Na efflux was reduced to about half, whether the saline was natural seawater (NSW) or a Na-free seawater (SW) Contrary to the effects of ionic concentration changes, the effects of strophanthidin were irreversible

We have further characterised the components of ^{24}Na efflux by testing the effects of K-free salines, cyanide and cold The omission of K from an otherwise normal artificial seawater decreased total ^{24}Na efflux by about 40%, but only by 15% in Na-free SW After strophanthidin, the removal of external K had no effect on the remaining efflux These results indicate that external K ions activate the strophanthidin-sensitive component of Na efflux[4] Cyanide (2×10^{-3} M), perfused for as long as 1 h reduced ^{24}Na efflux no more than did strophanthidin, or if applied after strophanthidin, had no effect

Finally, when perfusing saline was cooled to 3° C, efflux was reduced by 80% This extreme drop in temperature

Table 1 Percentage reduction of ^{24}Na efflux

	K free	Strophanthidin (10^{-3} M)	CN^- (2 10^{-3} M)	Cold (3° C)
Na SW	43±3 (14)	56±4 (9)	42±5 (3)	83±3 (7)
Na-free SW	15±2 (9)	53±3 (10)	30±7 (2)	81±5 (6)

Fractional inhibition of ^{24}Na efflux (mean ± s e m) expressed as (φ10K − φ*x*)/φ10K × 100, where φ10K is the number of counts before changing the conditions and φ*x* the number after that change, in NSW or in Na-free SW, changes to K-free SW, strophanthidin (10^{-3} M l^{-1}), CN^- (2 10^{-3} M l^{-1}), or cold Na was substituted by Tris or Mg mannitol[9] Number of experiments in parentheses

therefore not only decreased the strophanthidin-sensitive component of ^{24}Na efflux, but also the insensitive one

Data obtained with internal Na-sensitive electrodes indicate that after 1 h in Na-free saline, internal Na reaches a very low level (less than 3 mM) After 1 h of iontophoretic Na injection with currents of 50–100 nA, intracellular Na activities of cells immersed in Na-free SW are steady and close to those observed in NSW, 20–30 mM Since no entry of 'cold' Na from the bath takes place, we assume the specific intracellular ^{24}Na activity to be very much the same as that of the solution in the injecting electrode In these conditions, the calculation of the electrogenicity of the active transport system of Na becomes possible when the strophanthidin-sensitive clamp current (that is, the amount of transferred charge) is compared with the strophanthidin-sensitive ^{24}Na efflux (that is, the total amount of Na activity extruded) It is worth emphasising that intracellular Na levels of our injected cells in Na-free SW are similar to those of uninjected cells in NSW, our analysis thus applied to Na pumping in a 'normal' range of intracellular Na

When in Na-free (Tris) SW (Fig 3) the efflux and clamp current reached a plateau Introduction of strophanthidin produced a rapid, sharp reduction of both ^{24}Na efflux and clamp current to new plateau levels The differences between the plateau values were used as measures of pump electrogenic current, *I*, and of active Na efflux, φ In this particular experiment, the ratio *I* φ had a value of 0 60 Table 2 presents data from similar experiments on six cells Values of the electrogenic ratio vary from 0 40 to 0 65, and are clearly not related to the manner in which substitution for Na in the saline was accomplished It should be emphasised that this electrogenic ratio does not depend on the degree of active transport inhibition by strophanthidin since it results from the comparison between the decreases in ^{24}Na efflux and current observed on one and the same cell The mean figure of 0 56 taken at face value indicated that at least half of the Na actively extruded from the *Aplysia* giant neurone carries a net positive charge

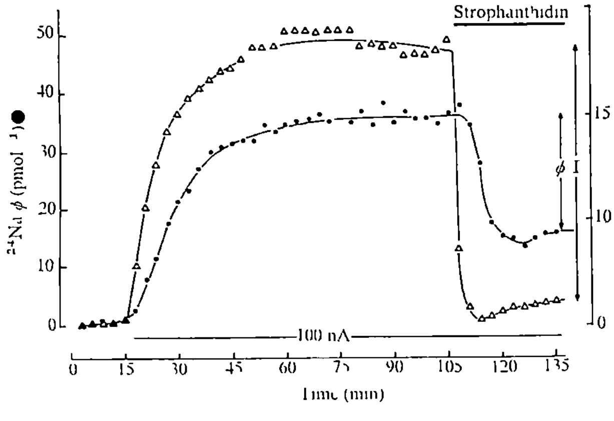

Fig 3 Efflux and pump current during constant ^{24}Na injection of a giant cell equilibrated for 1 h and perfused with Na-free (Tris) SW effect of strophanthidin (10^{-3} M) ^{24}Na injection (100 nA) was started about 15 min after beginning effluent collections and maintained from then on ●, Mean flux for each 3 min collection, △ clamp current applied for 30 s at the end of each collection period *I* and φ correspond to the strophanthidin-sensitive fraction of efflux and clamp current tabulated in Table 2

The electrogenicity and its inhibition, together with ^{24}Na efflux, by removal of external K or addition of strophanthidin, is consistent with a pump model in which extrusion of two Na^+ is balanced by the uptake of one K^+ This 2 Na 1 K ratio differs from the mostly evoked 3 Na 2 K figure In squid axon experiments, however, the data are consistent with such an exchange[2–4] In human blood cells, an apparent ratio 3 2 becomes nearly 2 1, if a correction is made for ouabain sensitive K–K exchange taking place in these cells[10] Our results seem to conflict more with Thomas' observations on snail giant neurones[7] He computed that only one of three or four Na^+ extruded carried net charge

Table 2 Clamp current (*I*), strophanthidin-sensitive efflux (Naφ) and the ratio *I* φ, for experiments in Na-free SW

Na substitute	pmol min^{-1} Naφ	*I*	*I* φ
Mg^{2+}, mannitol	20 8	8 6	0 41
Tris	19 8	9 9	0 50
Mg^{2+}, mannitol	17 0	11 1	0 65
Mg^{2+}, mannitol	24 0	13 2	0 55
Tris	22 0	14 0	0 64
Tris	20 7	12 3	0 60
			0 56 mean ±0 04 s e m

The discrepancy between these and our results might reflect a variation of a coupling Na K ratio under different experimental conditions[11–13] (for example, differences in electrochemical gradient) or differences in properties inherent in nerve cell membranes of different species We think that the answer to this question can be reached by further studies using our experimental approach in which ionic fluxes and their electrogenic impact can be measured simultaneously on a single neurone in different ionic and/or metabolic conditions

We thank Dr R C Thomas for supplying the Na-sensitive electrodes and participating in some of the experiments in which they were used This work was supported in part by a grant to L T from DGRST

Evolutionary significance of autogenous regulation

GOLDBERGER[1] has drawn attention to numerous reports relating both to prokaryote and eukaryote systems in which it has been shown that an enzyme may have, in addition to its own catalytic function, a regulatory role in determining the rate of its own synthesis He has suggested the term 'autogenous regulation' to describe such situations The term 'autoregulation' has previously been used by others[2,3] to describe this general phenomenon Autogenous regulation is, however, itself an example of a more widespread phenomenon, whereby a protein may have a regulatory function as well as a catalytic or structural role Thus for example, Slonimski and his coworkers[4,5] have suggested that in *Saccharomyces cerevisiae,* iso-2-cytochrome *c* regulates the synthesis, not of itself, but of iso-1-cytochrome *c,* and I have proposed[6] that in *Aspergillus nidulans,* nitrate reductase regulates not only its own synthesis, but also the syntheses of many catabolic enzymes

In an earlier paper[7], I speculated briefly on the possible evolutionary significance of this bifunctionality of certain proteins, suggesting that it might be a more widespread phenomenon than was at the time apparent Now that a number of other similar examples have been reported (see ref 1 for a list of references), it is worthwhile to develop these speculations further

I assume that, primitively, enzyme synthesis was unregulated For regulation to evolve, an element was required which must combine two specificities It had to be able to interact in some way with the apparatus of gene expression to ensure that the gene product was synthesised only when the environmental conditions of the cell required it It therefore also had to be able to recognise these environmental conditions The evolution *de novo* of such an element, with its two unrelated specificities, would pose problems There were already present in the cell, however, elements which had one of these functions At this point, it is simpler to consider the evolution of inducible and repressible systems separately

For inducible systems, the cell already possessed enzymes which had to recognise their substrates to function and it seems plausible that these would provide a starting point from which evolution could select the second specificity necessary for them to acquire additionally a regulatory function Although, for inducible systems, an enzyme would be an ideal candidate for evolving the function of regulating its own synthesis, it is by no means the only candidate Any other protein which interacted either with the substrate of the enzyme whose synthesis is to be regulated, or with some metabolite whose intracellular concentration was correlated with the concentration of that substrate, would also be suitable This may explain why the natural substrate is not the effector in some inducible systems Examples of this are xanthine dehydrogenase I in *Aspergillus nidulans* which is induced by its product uric acid but not by its substrate hypoxanthine[8], and the *Escherichia coli lac* system which is induced by allolactose, but not by lactose[9]

For repressible systems, there would also be a variety of possible candidates already present in the cell, which would be suitable for selection for a regulatory role These would include any protein which could bind either to the product of the pathway to be repressed, or to some metabolite whose concentration was correlated with the concentration of that product (for example, for some amino acid biosynthetic pathways, the charged amino-acyl tRNA) In several cases it has in fact been found that the first enzyme of the biosynthetic pathway, which recognises the end product or a related metabolite because it is subject to feedback inhibition, also has a regulatory role in determining the rate of synthesis of the enzymes of the pathway[1] These findings imply that the evolution of feedback inhibition may have predated repression

In both inducible and repressible systems, it is possible that selection for the modification of a catalytic protein so that it acquires additionally a regulatory function, may in some cases put demands on that protein such that it could perform neither catalysis nor regulation well In such cases, duplication of the gene specifying the protein, and subsequent divergence of the two gene copies, would allow each to be selected for one of the functions only This would result in genes whose protein products would now seem to have only a regulatory function, but it is possible that such proteins might still contain in their amino acid sequences 'fossil' evidence of their evolutionary origin

Beyrouther, *et al*[10] have determined the amino acid sequence of the *E coli lac* repressor, and have found no similarities between it and those parts of the *β*-galactosidase sequences which are known They argued that it was unlikely therefore that the two proteins had evolved from a common ancestor The *lac* repressor could have evolved, however, from some other cellular enzyme which bound allolactose

matters arising

Two-stage transformation *in vitro*

THE evidence for malignant transformation of cells *in vitro* by the combined action of benzo(a)pyrene (initiator) and phorbol ester (promoter), presented by Lasne *et al*[1] is very striking I feel, however, that they fail to bring out the true nature of their results

The benzo(a)pyrene treatment of the primary rat fibroblasts was at the third passage, yet the dramatic increase in the percentage of transformed colonies was delayed until the thirty-fourth passage, when the incidence became 20 5% (benzo(a)pyrene alone) and 33 0% (with phorbol) By this time the 'primary' fibroblast culture was becoming senescent This was indicated by the rise in frequency of transformed colonies in the controls to 11 5% by the fortieth passage

It seems that we are not observing an increase in the rate of transformation but rather the selection of already transformed clones in a mixed population of cells The phorbol seems to increase the selective advantage of transformed cells by 50% There is no sign so far of two-stage transformation

Two-stage transformation becomes apparent only when 2-d-old rats were injected with 2×10^6 cells At the fortieth passage, although 42 5% of the cells were transformed by *in vitro* standards, they produced no tumours on injection At the same time, cells also exposed to phorbol produced tumours in every rat There has been a malignant transformation of the phorbol-treated cells which only becomes apparent on injection into animals

The 'two stages' of malignant transformation are therefore, first, the transformation in colony morphology as seen *in vitro*, which is induced by benzo(a)pyrene After 30 passages these transformed cells have a selective advantage and grow at the expense of the untransformed cells The selective advantage is slightly enhanced by phorbol Second, the transformation of stage 1 cells which is cryptic *in vitro*, but apparent on injection into young rats by the production of tumours This is induced, or perhaps merely accelerated, by phorbol

A J BATEMAN

Paterson Laboratories,
Manchester, UK

---

[1] Lasne, C, Gentil, A, and Chouroulinkov, I, *Nature*, **247**, 490–491 (1974)

DR LASNE REPLIES—Thank Dr Bateman for the analysis of our results in our paper I think however, that the problem is not so simple

So far as we know, the increase in the percentage of transformed colonies (11 5% by the fortieth passage) in tissue culture, does not necessarily indicate senescence On the contrary, it shows and confirms the beginning of an *in vitro* spontaneous cell transformation[1–3]

When Dr Bateman speaks about the senescent cell selection theory, he perhaps thinks of the Prehn's 'cloning selection theory'[4] In this case, we refer him to reports[5–7] that in chemical carcinogenesis, no selection of pre-existing transformed cells has happened

Concerning the action of phorbol ester, and in general the action of the other promoters, on the growth of pre-existing transformed cells, we wonder whether the author is aware of studies on carcinogensis *in vivo* Our results are interpreted in correlation with the model established *in vivo* In previously initiated animals, the promoter increases the tumour incidence, and shortens the latent period[8] *In vitro*, the phorbol ester gives similar results increasing the number of transformed colonies, and accelerating the tumour development after inoculation of the cells in animals But we have not discussed the general theory of cocarcinogenesis, which requires greater attention Our paper merely raises this question

Lastly, these results have been obtained and presented to the scientific public Each investigator may present his own interpretation We have proposed one

The Musgrave Block-Amadeus Basin Complex

DAVIDSON[1] suggested that a plate tectonic model, involving continental collision, could explain the features observed in the Musgrave Block-Amadeus Basin area of central Australia Several significant features of the area are not accounted for in his model and these are, I believe, of sufficient importance to warrant modification of the model

In Davidson's model the Giles Complex is considered to represent part of an ophiolite thrust belt, originating in layers 2 and 3 of the oceanic lithosphere Bearing in mind the form of ophiolite sequences, however (see, for example, the discussions at the Penrose Field Conference[2]), there is no indication that rocks of the Giles Complex are in fact ophiolites, even if the absence of cherts and pillow lavas in the area is ignored There is a marked absence of olivine rich rocks, a deficiency of ultramafic rocks in general, and all parts of the Complex show some features characteristic of stratiform intrusions, such as cumulate textures, cyclic units, rhythmic layering and associated 'sedimentary type' structures[3,4] Repetition within the sequence of mafic–ultramafic units is largely a result of the igneous layering and cyclic units Some intrusions in the central part of the Complex show features characteristic of crystallisation under high pressure (that is, near the base of the crust[4]) and such features are incompatible with an oceanic ophiolite type origin Furthermore, there is evidence that the separate bodies of the Giles Complex show a depth stratification[4] which is inconsistent with Davidson's model

Several structural aspects and relationships are also inconsistent with that model The bodies of the Giles Complex were intruded into granulite facies rocks—chilled margins occur in places, and unfaulted boundaries are transgressive to the earliest recognisable folds in the granulites[4,5] Relatively minor, local low-angle faults have affected some intrusions such as Gosse Pile[6] and Kalka[4] The faulting occurred under conditions of high pressure and temperature, equivalent to granulite facies[7], and should not be confused with the much larger scale mylonitic faulting such as occurred in Woodroffe, Hinckley and Davenport The low-angle faulting was responsible for the partial dismembering of parts of the Giles Complex But even though the felsic units of Gosse Pile were removed in this way they can be related to the more felsic Kalka intrusion which occurs to the west, along the strike of the fault, and therefore the deformation is unlikely to have caused the total removal of the supposed pillow lavas and pelagic sediments

After the minor phase of high pressure and temperature thrusting there followed a period of regional deformation (F_2) involving both granulite facies rocks and the Giles Complex bodies (refs 3 and 4) This was followed by the intrusion of picrite plugs and olivine dolerites, and a third period of folding (F_3), before the deformation along the major E–W mylonite zones, such as the Hinckley Fault

The eastern Musgrave Ranges had a similar, complex structural history before faulting took place along the major Woodroffe Fault and Davenport Shear[8] That indicates that the Giles Complex had intruded granulite facies rocks and, in part, had crystallised and been deformed under conditions of high temperature and pressure and had undergone two further periods of deformation before major movement along the large thrust zones They are therefore obviously not ophiolites

The presence of the major thrust zones and the large volumes of mafic intrusives, indicates that this area has been one of significant tectonic activity Apart from the exposed thrust zones and rocks of the Giles Complex, a marked gravity high extends from the Musgrave Block to the Indian Ocean This is the Ankatell-Warri Ridge[9,10] These features all suggest a major uplift along the thrust zones in this area, such that upper mantle material has been brought near the surface There is evidence to suggest that the rocks to the north of the Woodroffe Fault are of lower metamorphic grade (amphibolite facies) than those to the south (granulite or granulite–amphibolite transition facies) and also have different tectonic histories[8]

Similarly, the Olia Gneiss containing nappe structures of Upper Proterozoic rocks in the southern Amadeus Basin (section *c–d* in Davidson's article) consists of amphibolite, migmatite and schist, and is not granulite facies terrain This leads me to suspect that areas to the north and south of the major thrust zones are not as similar as they may appear to be at first, and a preconvergence period of spreading within a single continent may not be necessary

A modified model can be proposed, in which a southern Musgrave craton collided with a northern Musgrave (?Arunta) craton along the line now marked by the thrust zones of the Musgrave Block and by the Ankatell-Warri Ridge The southern Musgrave craton was forced up along the thrusts, bringing to higher levels the rocks of the lower crustal granulite facies and the high pressure intrusives of the Giles Complex Further west it did not rise so high and higher level (lower pressure) intrusives and metamorphic rocks are exposed[11] Because of the uplift, upper mantle material would now be nearer the surface, giving rise to the gravity anomalies At a very high level the ophiolite complexes, folded sediments and lower grade (including blueschist) facies metamorphics would have been found, but considerable erosion has removed these, and the remnants may be found in the Upper Proterozoic Inindia and Winnalla Beds and in the Cambrian Mt Currie conglomerate, as suggested by Davidson

The 'Woodroffe-Ankatell Suture' may thus be regarded as a major tectonic boundary and, in the same way as the Insubric Line of Europe may mark the site of a Mesozoic collision trench (for example, the Ivrea Zone[12]), the 'Woodroffe-Ankatell Suture' may mark the site of a Proterozoic collision trench In the Australian example, however, a considerably deeper section of the boundary is exposed If this model is correct it implies that the radiometric ages of rocks to the north of the Woodroffe Fault should be younger than those to the south

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature* The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered

Musgrave Block

MOORE'S comments require that some modification be made in the detail of the original model[1] The degree of modification, however, is not nearly as extensive as might be implied from the criticisms he presents

His arguments are related principally to two points First, the nature of the mafic-ultramafic rocks of the Giles Complex, their origin and mode of emplacement Second, the time-space relationship between the colliding continental blocks My following comments are concerned with answering objections raised by Moore in regard to these points

The geological environment in which layered or stratiform mafic–ultramafic complexes are formed is still uncertain and it is possible that there are several such environments[2,3] There is definite evidence, for instance, indicating that stratiform complexes may form at spreading centres[3,4] and thus become significant parts of the oceanic lithosphere As such they may be later tectonically emplaced along collision boundaries This suggestion is given further support by the presence of cumulate textured, layered mafic–ultramafic rocks within known ophiolite sequences[5,6] (assuming ophiolites to represent ancient oceanic lithosphere) Furthermore, it has been suggested that stratiform bodies may well characterise Proterozoic ophiolites[3] It is also significant that cumulate, layered rocks within ophiolites tend to be more deformed than other types of stratiform sequences This is the case with the Giles Complex rocks[7,8]

The near parallelism of primary and tectonic layering, the close association between thrust surfaces and the layering, the presence of thrust faults at contacts with basement granulites and the gross correlation of regional trends for the mafic–ultramafic belt and the major thrust faults[7,8], all suggest a strong tectonic relationship between the emplacement of the Complex rocks and the thrust zone This is best explained in terms of a 'subducting oceanic lithosphere' model In addition the marked similarity between 'alpine-type' flow layering and deformation and the tectonic layering observed in parts of the Complex[7,8] cannot be ignored in interpreting the origin and mode of emplacement of the sequence

The presence of granulite facies metamorphism, annealed textures and other high P/T reactions are not incompatible with the model Subduction to depths of the order of 30 km would produce pressures and temperatures (10 kbar, 800° C) within the lithospheric slab[9] suitable for the development of the observed phenomena[12]

The question then arises as to the order of events as recorded in the rocks, also taking into account the phases of folding that have affected the layering The events from oldest to youngest appear to be first, the ductile shearing, metamorphism and annealing resulting in a gabbro gneiss zone, second, the folding (F_2) of this tectonic layering[8], third, the folding (F_3) of the Complex[8] on a more regional scale, and fourth, brittle thrusting

The original model again gives the best solution The oceanic lithosphere is first underthrust to depths sufficient to produce metamorphism, annealing and so on as indicated above Further underthrusting produces a maximum compression axis parallel to the layering and gives rise to F_2 folding[11] With the development of actual collision between continental blocks a period of tectogenesis and orogenesis (uplift) results in F_3 flexuring of the subducted lithosphere, slivers of which are consequently overthrust (obducted) on to the 'active' continental block[1] The latter event produces the phase of brittle faulting (major thrust faults) and mylonitisation This sequence of events also explains the lack of a metamorphic phase in the granulites correlateable to that producing the tectonic layering in the rocks of the Complex

Moore's comment regarding the difference in metamorphic grade in the basement rocks north and south of the thrust zone is a valid one and recent work also indicates differences in structural geometry[12] This, in fact, makes a collision model even more acceptable, as recourse to the tenuous concept of 'oscillation' is no longer required

In conclusion, let me point out that the fundamental interpretation of the regional geology of the area by means of a plate tectonics model is still valid and is supported by other comments made by Moore in his discussion The distribution of distinctive tectonic elements and their correlation with such a model remains the essential feature of the hypothesis The only real alteration is that of distinguishing as separate entities the Musgrave-Mann granulites (proto-Musgrave block) to the south and the gneiss–amphibolite terrain (Arunta? block) to the north of the thrust zone

Ethylene and soil fungistasis

SMITH[1] has reported that ethylene is a causative agent of soil fungistasis, that its production in soil varies with organic matter and that in contrast with other work[2,3] it can occur in aerobic soil conditions His second claim is repetition of earlier work[3], more recent observations[4] suggest that soil anaerobiosis is necessary to mobilise substrates[5] for ethylene formation by soil microorganisms

We have attempted to reproduce Smith's experimental conditions to investigate further the effect of oxygen on ethylene formation in soil and the significance of ethylene as a fungistatic agent The soils used, which passed through a 0 1-cm sieve, were a chalk loam (10 3% organic matter) and a sand (1 4% organic matter) The soils were packed in open glass tubes and the water tension maintained at field capacity, that is, the moisture content of soil after it had drained from a waterlogged state on filter paper overnight The oxygen concentration in the loam was reduced from atmospheric to less than 0 1% and the ethylene concentration reached 28 v p m within 2 d at 25° C In the case of the sand, oxygen remained at atmospheric levels after 15 d and the ethylene concentration never exceeded 0 1 v p m When the experiments were repeated with soils which had been sieved to 0 2 cm instead of 0 1 cm, they did not become depleted in oxygen and no ethylene was detected When the top of the tube was sealed, however, the concentration of oxygen decreased and ethylene was detected

Whereas it has clearly been shown that ethylene can be fungistatic aerobically[1], it is neither fungistatic to nor metabolised by an ethylene-producing soil fungus, *Mucor hiemalis*[6], further, there is no evidence that it is fungistatic in the soil under the conditions in which it is normally formed, that is anaerobic, since it is almost certain that anaerobiosis is itself fungistatic[7]

Ethylene formed in anaerobic zones, however, could diffuse to and act in aerobic zones if it were not lost by further diffusion or metabolism[8] Germinating seeds also produce ethylene[9], presumably by an aerobic process, and this could be important in the seedling's resistance to attack by fungal pathogens

DR SMITH REPLIES—Most of the points raised by Lynch and Harper have been clarified by our latest research[1] We have shown clearly that spore-forming anaerobic bacteria are the major producers of ethylene in soil, that ethylene is produced in anaerobic microsites in even relatively dry soil, that the anaerobic microsites result from the activity of aerobic microorganisms, and that the aerobes, in turn, are inactivated by the ethylene diffusing from the anaerobic microsites In essence, we have described a self-regulating cycle in soil that controls microbial activity

Other soil microorganisms, including *Mucor hiemalis,* may produce ethylene but the quantities will be limited by their own sensitivity to ethylene as most soils are fungistatic most of the time Also, our research has shown that ethylene production in soil is relatively insensitive to heat treatments, which rules out *M hiemalis* as a major producer because it is killed by even mild heat treatments

Claims that fungi are insensitive to ethylene must be interpreted carefully because in my original paper it was pointed out that the fungistatic action can be overridden by nutrients Thus, results obtained with ethylene in pure culture cannot be extrapolated to unsterilised soil

tRNA and ageing

HOFFMAN and McCoy[1] have reported on the nucleoside composition of tRNA from mature and old mosquitoes and mature and old mice They reported that no alterations in the total population of tRNAs occur during ageing The authors "point out the danger of interpreting chromatographic changes in tRNA or changes in activity of tRNA methylases in terms of the final degree of modification without actually analysing the tRNA" I could not agree with them more but write to point out that they did not analyse the tRNAs whose chromatographic profiles are changed They analysed the crude mass of tRNAs which in metazoa may number more than 100 The isoaccepting tRNAs which differ in a variety of systems such as tumour tissue and differentiating tissue, are invariably very few in number and often they are minor species For example, it has been shown in Ames' laboratory that in *Salmonella* tRNA$^{\mathrm{His}}$ is the control agent for the histidine pathway operon In a mutant in which the operon is always open with the consequent constitutive status of the pathway, there is an isoaccepting tRNA$^{\mathrm{His}}$ which differs from its counterpart in the wild type by the lack of conversion of two Us to ψs[2] If we assume only 64 tRNAs in *Salmonella* and an average of four ψs per tRNA no analytical method could have established the absence of two ψs out of 256 Under the circumstances, a mass analysis of tRNA mixtures in which the preponderance of the population has not changed is meaningless

The senior author has shown earlier in aged mosquitoes a changed elution pattern in but five tRNAs[3] Only an analysis of any of these from young and aged mosquitoes would have any meaning This, of course, is technically impossible at present The authors refer to earlier work by Frazier and Yang who found no difference in elution patterns of tRNAs in young and old mouse liver[4] An examination of that paper reveals that only nine tRNA profiles were compared and most of these were done with the RPC-2 system which is known to have inadequate resolving power for the separation of isoaccepting tRNAs May I emphasise again to those who are not conversant with this field, that a very few, indeed sometimes but one regulatory tRNA, can have profound physiological effects Thus, for example, Jacobson has shown that a single tRNA can control the eye colour of *Drosophila*[5]

[4] Frazier, J N, and Yang, W K, *Arch Biochem Biophys*, **153**, 610 (1972)

[5] Jacobson, K B, *Nature new Biol*, **231**, 17 (1971)

DR HOFFMAN REPLIES I concur with Dr Borek when he emphasises that a deficiency in one modified nucleoside in one regulatory tRNA can have profound physiological effects I contend, however, that if that deficiency is due to altered activity of a tRNA-modifying enzyme, then all tRNAs which are substrates for that enzyme will show the same nucleoside deficiency as the regulatory tRNA It is then quite likely that nucleoside composition analysis of total tRNA would show a significant deficit in one compartment

The work of Singer *et al*[1], which Dr Borek quotes, is an excellent example It is true that lack of conversion of two Us to ψs in the tRNA$^{\mathrm{His}}$ of the *his T* mutant of *Salmonella* is directly responsible for constitutive derepression of the histidine operon It is equally true, however, that many other *his T* tRNAs lack this conversion Singer *et al*, showed directly that tRNA$^{\mathrm{Tyr}}$ and tRNA$^{\mathrm{Leu}}$ I and II from *his T* have altered chromatographic mobility when compared with the wild type They also pointed out that nearly half (5/11) of the *E coli* tRNA sequences known at that time contained ψ in the same position as in wild type *Salmonella* tRNA$^{\mathrm{His}}$, presumably as products of a *his T*-like enzyme If one applies that fraction to Dr Borek's assumed 64 *Salmonella* tRNAs, then in *his T* mutants 32 of them would each be missing two ψs for a total of 64 (not two) out of 256, a 25% deficit in ψ which would be readily apparent in a comparison of the nucleoside composition of total tRNA from *his T* and wild type *Salmonella*

Dr Borek also refers to work on the tRNA involved in suppression of the vermilion mutation in *Drosophila*[2] In a detailed study of the mechanism of this suppression, Twardzik, Grell and Jacobson[3] suggest that it is due to lack of an enzyme which modifies tRNA$^{\mathrm{Tyr}}$ They also state that "other tRNAs may be expected to be altered by the hypothetical modifying enzyme" Again I would predict that nucleoside composition analysis of total tRNA from the suppressor strain would show one component significantly deficient in comparison with wild type *Drosophila* tRNA

Our work on tRNA and ageing has been strongly influenced by Dr Borek's pioneering research on tRNA methylases, in particular the report by Mays, Finch and Borek[4] on the decline in activity of these enzymes during senescence of rodents In that report tRNA methylase activity in crude protein fractions, as measured *in vitro* by methyl saturation of total *E coli* tRNA, declined with age This decreased activity was attributed to increased glycine N-methyltransferase activity which would produce S-adenosyl-homocysteine, an inhibitor of tRNA methylases The methods used and the discussion given in this paper were directed toward total tRNA methylase activity and hypomethylation of total tRNA during ageing Based on this and my above discussion, I still maintain that it was proper for us to search for deficiencies of modified bases in total tRNA as a function of age Having found no such deficiencies, I must stand on our previous conclusion that tRNA modifying enzymes have no significant role in biological ageing[5]

reviews

SESPA, SCRAM, AIAA *et hoc genus omne*

Scientists and Public Affairs Edited by Albert H Teich Pp xi+315 (MIT Series in Comparative Politics) (MIT Cambridge and London, 1974) $14 95

THIS highly readable volume has, in essence, three themes scientists *en masse,* scientists as politicians and politicians as scientists These themes are adumbrated by five authors, eased to the reader's attention by a general preface, five individual forewords by as many pundits, and a postface It is an intriguing practice perhaps the run-of-the-mill multi-author scientific text would be more digestible if consumed with an antipasto of comprehensible individual forewords!

The first essay, by Daniel Rich, is concerned with the ethos and functioning of (American) scientific and technical societies For purposes of exemplification he depends especially on two bodies concerned with meteorology (AMS) and aerospace (AIAA), with glances at physicists, chemists and others One hotly contested theme is the role of such societies in connection with professional status Whereas engineering societies, and more especially legal and medical bodies, have a professional licensing function, scientific societies, in America at least, initially fought shy of this but are beginning to follow suit It is most interesting to see this contentious topic dealt with by a competent political theorist who casts a cold eye on professional pretensions A few quotations will convey the flavour "Competition is anathema to professionalism " "The AMS code [of professional ethics] rarely has been enforced" "The public may be protected [by a code] but the profession is also protected by the fiction that all licensed professionals are competent and ethical until found otherwise by their peers"

Another theme discussed by Rich is the relationship between the membership, the elected officers and the permanent officers of a scientific society He believes that the form of democracy often exists without the substance the permanent staff are apt to have disproportionate influence Unlike the Civil Service so bitterly attacked by Marcia Williams, however, it seems that the political 'masters' of the full-time officers are quite content with the arrangement, because generally there is little pressure for change American scientific societies are only slowly beginning to become involved with national politics (the third theme of the essays) and there is strong resistance to such involvement Possibly, when this trend develops, as it certainly will, there will be more conflict between elected and appointed officers

The second essay is by Anne Hessing Cahn, and concerns the involvement of American scientists in the controversy that raged through Washington a few years ago about the proposed deployment of anti-ballistic missiles Her study was based upon detailed interviews, or correspondence, with a sample of 152 leading scientific participants in the controversy identifying the sample seems to have been a research exercise in its own right The 152 scientists are classified in all sorts of ways—according to disciplines, type of employment, 'distinction' measured in various ways (including the number of citations of their papers), connection with the political establishment, political views, and of course their attitudes to the ABM, and all sorts of cross-correlations are established The interest of this chapter lies at least as much in the individual vignettes and insights presented in vigorous prose, as in the general conclusions drawn, and it well deserves reading The 'insiders', including several members of PSAC, the President's Scientific Advisory Committee, were deeply indignant at the way that their advice was either not requested or else ignored, and it seems that though formal advice to the president is protected by secrecy, several advisers came to think that they were entitled to publicise their personal views The most active campaigners, however, were 'outsiders'—that is, people neither working in the missiles industry nor yet in the inner advisory circles in Washington—opposed to the ABM, some of them were hostile to 'insiders' as a class (*vide* Professor Dash's bold assertion "Inside advisors are prostitutes") The outsiders' influence seems to have been, not on the executive, but on the general public, whom they energised to form active groups like SCRAM (Sentinel Cities Reject Anti-Missiles) and on members of congress One is driven to wonder whether British activists could reasonably hope for a comparable effect by convincing members of parliament

David Nichols next presents an essay on the various bodies which were set up specifically for scientists, either in isolation or in cooperation with non-scientists, to exert political pressure This essay returns to the theme touched on in the first chapter, the debate within the conventional societies as to the appropriateness of political action under their auspices (It seems, from both chapters, that physicists are still in the van of political activists) Up to now, most political action seems to be the preserve of specially constituted bodies such as the Federation of American Scientists (FAS), or Scientists for Social and Political Action (SESPA) These range from properly organised and financed lobbying bodies such as FAS to bodies whose principles will sound very familiar to academics nowadays, SESPA leaders assert that their group is a "non-organisation—a group with no officers and no constraints on membership", for "if groups are to struggle against non-participatory, undemocratic structures, it is necessary that they don't replicate such structures in their own organising" Such bodies often prefer concentrated local action Nichols, who is sceptical of the efficacy of such groups in influencing the executive branch (he does not discuss the legislature) remarks "How local action, not to mention local action by a non-organisation, can combat a ruling elite is, to say the least, not self-evident" There are lessons to be learnt by comparing Nichols's evidence and conclusions with those offered by Anne Cahn in the preceding chapter

Albert Teich next offers a fascinating survey of the attitudes and modes of life of the multi-national scientific staff of a number of European laboratories, foremost among them the ESTEC (space) laboratory in the Netherlands, CERN near Geneva, and Ispra, a former Euratom laboratory by Lago Maggiore in Italy They range from the high morale and well-defined function of CERN to the disorganisation and uncertainty of Ispra, both of which emerge clearly from many interview statements This chapter does not lend itself to summary, but makes most instructive reading, especially for those whose attitudes to European integration have congealed The one generalisation which can safely be made is that national scientists readily acquire a European outlook in these laboratories (even the indifferent ones), even most of the British, poor linguists that they still are, become more European in outlook when exposed to high concentrations of 'foreign' colleagues

The last chapter, by the late R David Gillespie, is devoted to the politics of cybernetics in the Soviet Union Norbert Wiener's pioneering ideas of the forties first ran foul of the Great Scientist's henchman, Zhdanov, on grounds based partly on the orthodoxies of dialectical materialism, and partly on the not-invented-here syndrome Later, cybernetics became part of Soviet orthodoxy In the words of David Lerner's introduction, "Gillespie charts the shift of official policy from dogged antagonism to euphoric embrace" This is a piece of very solid detailed politico-scientific history

In the postface (this must be one of the few nearly Latin words invented in the twentieth century!), Eugene Skolnikoff outlines the increasing involvement, since the Second World War, of MIT in the field of science and public policy

Overall, these essays, which although properly quantitative in approach are refreshingly clear and free of sociological jargon, go down as easily as a dish of oysters In consuming them, however, one should carefully extract the pearls of wisdom which one will certainly encounter in the process

ROBERT CAHN

Statistics in ferment

Theory of Probability A Critical Introductory Treatment Vol 1 By Bruno de Finetti Translated by Antonio Machi and Adrian Smith Pp xix+300 (Wiley Series in Probability and Mathematical Statistics) (Wiley London and New York, April 1974) £7 50

THE foundations of statistics are in dispute, and have been for many years Scientists for the most part think they need—and believe they can have—an objective language of statistics by which they can evaluate and communicate their results Usually they use significance tests, estimation procedures, and confidence intervals, and are happy to overlook the fact that most enquirers into the logical basis of this so-called 'repeated-sampling' methodology have concluded that it is unsound R A Fisher, geneticist as well as statistician, H Jeffreys, geophysicist, and I Hacking, philosopher, have been three outstanding critics Fisher, on whose early work much of the repeated-sampling development relies, was fulsome in his condemnation of later developments, and in *Statistical Methods and Scientific Inference* (1956) sought to stem the tide, allowing, apart from the simple test of significance, only those repeated-sampling methods which he thought made full use of all the information in the sample Not only was he unable to provide a unitary method for statistical inference he formed the opinion that no such method was possible Jeffreys, who had never regarded the repeated-sampling theory as more than a passing aberration, developed in *Theory of Probability* (1939), an account of the objective Bayesian theory, in which the probabilities of hypotheses are modified by the likelihood obtained from experimental results, according to Bayes' Theorem Hacking, surveying the whole field in 1965 in *Logic of Statistical Inference,* opined that there was much sense in what both Fisher and Jeffreys had to say, especially in criticism of the repeated-sampling theory, and concluded that the one element common to both their philosophies—the likelihood—could be elevated into a method in its own right, and, furthermore, that it could be extended a little into the repeated-sampling domain to give a satisfactory explication of the core of Fisher's fiducial theory and Jeffreys's theory for the estimation of location and scale parameters

As if this was not controversy enough, there are those who say that an objective theory of scientific data analysis and reporting is impossible (and who can blame them for pointing to the existing confusion as evidence?) Though the point of view has its origins in the writings of J M Keynes and F P Ramsey, its principal exponents have been L J Savage (*The Foundations of Statistics,* 1954) and Professor Bruno de Finetti In the present volume the latter offers the first half of his "necessary document for clarifying one point of view in its entirety"—the subjective Bayesian point of view The work was first published in Italian in 1970, and for English readers has been divided into two (as well as being most admirably translated)

Nobody should attempt to judge this work without prolonged reflection It must be bought, read, and then left lying around so that it can be assimilated over the years No book on statistical inference and the foundations of probability ever persuaded anybody directly, for we all make up our own minds by subjecting them to a thousand subtle influences Only once we are persuaded do we see the virtues of a clear and logical development, Professor D V Lindley may be cited as an example, for he writes, in a foreword to this volume, 'that it is a book destined ultimately to be recognised as one of the great books of the world' A reviewer, mindful of Pascal's wager, might be well advised to agree, but I have my doubts De Finetti's volume 1 presents only half his case, and since his discussion of inductive reasoning and statistical inference is not reached until towards the end of volume 2, we must bide our time What is already certain, however, is that de Finetti is giving a masterly clarification of 'one point of view in its entirety', raising the level of discussion to unsurpassed heights I await volume 2 with impatience

A W F EDWARDS

Population structure

Methods and Theories of Anthropological Genetics Edited by M H Crawford and P L Workman Pp xviii +509 (A School of American Research Book) (University of New Mexico Albuquerque, December 1973) $20

WHAT can 'anthropological genetics' be? That part of genetics pertaining to man, usually called human genetics? No, this book is really about genetical anthropology, or that part of anthropology whose study is made more fruitful by an appeal to genetical principles and genetical information, a sibling of social anthropology and physical anthropology In particular it is the study of population structure and population relatedness using models and methods developed by geneticists, and gene frequencies as a primary source of information It arose because of the conjunction of a vast increase in the amount of genetic information available and the advent of electronic computing, and has particular topicality because of the modern discussion of racial differences

About ten years ago some geneticists with a mathematical bent started applying their techniques to some of the problems of anthropology, and began developing new techniques appropriate to the computer age Although anthropologists had earlier assimilated the pioneering work on the distribution of the human blood groups, they tended to regard this incursion with suspicion, but soon came to terms with the new approach The success of the invaders owed much to the fact that not only did the geneticists bring their own tools they also brought a wide range of statistical and computational expertise that was, for the most part, new to anthropology

This volume is a revised and extended report of a conference held in early 1971, and consists of nineteen papers (the last being a useful review of the remainder) followed by nearly six hundred references These are interesting in themselves a histogram for the years of publication shows a close fit to an exponential rate of increase with a doubling time of five years (20 in 1960, 40 in 1965, 80 in 1970), and is an indication of the impossibility of being really up to date with such a book

The volume is an excellent summary of the present state of play in the field, and would provide a good entry for anyone wishing to join in There are one or two notable absentees from among the contributors, but readers will soon be led to their work through the references It is difficult to escape the impression, however, that genetical anthropology is at a somewhat adolescent stage, reflected by methodological controversies about matters of no great moment, and by the fact that in all that has been written one can discern nothing that is really surprising, no great contribution to knowledge or understanding that takes the subject beyond the merely documentary It is possible, indeed probable, that once the field has settled down something will be forthcoming, and this book may serve as a useful appetiser

Pharmacology of neurones

Transmitters and Identified Neurons in the Mammalian Central Nervous System By Andris K Tebécis Pp xvi+340 (Scientechnica Bristol, May 1974) £11 50

MANY books and symposia have appeared in recent years on the subject of neurotransmitters in the mammalian central nervous system, but Dr Tebécis's monograph deals with the topic in a highly original manner

One of the most powerful techniques for studying the actions of transmitter substances on neuronal receptor sites in the brain or spinal cord involves the recording of the electrical activity of single neurones while applying transmitters and other drugs in a highly restricted manner on to the surface of the cell from which such recording is being made Such micro-applications are achieved by the electrophoretic ejection of minute quantities of chemical from the fine tip of a glass microelectrode situated near the cell surface The effects of several different substances may be tested on the electrical activity of a single neurone by using multibarelled arrays of such microelectrodes Such studies allow one to define the neuropharmacological properties of individual neurones in the CNS, that is, whether they are capable of responding to various possible transmitters, and if so to define what particular type of transmitter receptor is involved This approach can be used to determine which transmitter when applied to a neurone most closely mimics the response seen when transmitter release is induced naturally by stimulating one or other of the neurone's presynaptic connections In this way one may determine the identity of the transmitters used by various neuronal pathways in CNS These experimental approaches have been widely used in recent years, and a bewildering plethora of results is available in the literature

Dr Tebécis has undertaken the Herculean task of collating much of this information into a meaningful pattern He has been helped in this by the novel approach he has taken It has become increasingly clear that the neuropharmacological properties of different types of neurone in the CNS can vary widely Results obtained by the micro-iontophoretic application of drugs and transmitters to randomly selected single neurones in any given region of the brain are thus likely to be extremely difficult to interpret, since several different neurone types are likely to be recorded from Far more consistent results are obtainable, however, if recordings are made selectively from only one type of neurone in any given brain region This may be done, for example, by using only neurones which can be identified as responding to antidromic stimulation of their axonal bundles at some remote site in the nervous system For example, spinal cord motor neurones may be identified by their antidromic response to the electrical stimulation of motor nerves

Dr Tebécis reviews what is known from neurophysiological studies of the pharmacological properties of "identified" neurones in various areas of the CNS Successive chapters deal with the spinal cord, brainstem, cerebellum, diencephalon, basal ganglia, limbic system, cerebral cortex and retina In each chapter detailed discussion is given of the results available for each of the various identifiable neurone types from which single unit recordings can be obtained In the brain stem, for example, fifteen different categories of neurone are described In each case any biochemical or histochemical data that are available concerning the distribution of transmitter-specific neuronal pathways are also reviewed The emphasis is on the actions of acetylcholine, the excitatory amino acids, GABA, glycine, catecholamines and 5–HT The author, however, also indicates the large gaps in our knowledge of the pharmacology of cerebral circuitry, pointing out the many instances in which the identity of the transmitters used at CNS relays remains unknown The book is well illustrated, and very up to date The bibliography is extensive and will be a valuable collection of source material for those interested or involved in this field

The organisation of material in the book means that it has more the nature of a catalogue of useful information than a monograph, but the catalogue will nevertheless prove very useful to many neuroscientists The author assumes that the reader has a fairly high level of knowledge of the physiological and pharmacological workings of the nervous system, so the book will appeal mainly to a small number of scientists or graduate students with this necessary expertise and interest They will, however, be grateful to Dr Tebecis for his critical and authoritative review

LESLIE IVERSEN

Science lessons

Science for the People The Origins of the School Science Curriculum in England By David Layton Pp 226 (Allen and Unwin, London, January 1974) £3 55

PROFESSOR LAYTON's well-written book ought to be made compulsory reading for all those scientists, administrators, civil servants and politicians who have anything to do with science education

By looking at the Victorian roots of the "Science for the people" idea, Layton has exposed many of the fundamental tensions in science curricula which still plague us From the beginning there were clashes in attitudes towards both method and ideology of science teaching What was science education for? Should it teach the "science of common things", or be more concerned with "applied" goals? Each viewpoint was intimately connected with political and social ideas Through studies of Richard Dawes, J S Henslow, Henry Moseley and other educationalists, and through curriculum analysis, plus some good political history, Layton has been able to synthesise a view of the past which has direct relevance today

There are, however, several things in the book which indicate a slight historical amateurishness Anachronistic social theory is one The book claims, for example, that amongst some educationalists of the 1850s, "Elementary schools were conceived primarily as instruments of social control" Possibly true, but this is much too theory-laden for the historian's palate The general aim of the book is unhistorical, too Layton has written the first seven "historical" chapters largely as a background to an almost totally theoretical chapter 8

But this is no more than a professional quibble The book itself has a value far greater than that of most historical works And Professor Layton has done science education an extremely important service

JAMES FRIDAY

Protozoa with lashes

The Ciliates By A R Jones Pp 207 (Hutchinson London, April 1974) £3 50 boards, £2 paper

MY first impressions of this little book were similar to those of a research student who, in the local bookshop, announced that it looked dull and uninteresting But first impressions can be misleading and I subsequently discovered the written content to be of a better quality than the visual appeal

The subject matter of the book is wide including chapters on the form, fine structure, locomotion, feeding, nutrition, reproduction, growth, taxonomy, and economic importance of ciliated protoza In general these chapters are readable, interesting and up to date although in places the style is rather slack A complete chapter devoted to osmoregulation and ion control is a refreshing feature not usually included in such textbooks and reflects the personal interests of Dr Jones The book is obviously written with some enthusiasm for the subject and I found several pieces of new and useful information not included in other texts I am not enthusiastic about the general format of this series of books and in this one I would have liked to have seen more original illustrations In several places I felt that a good diagram would have made the description simpler and more concise

As in all modern textbooks there is the inevitable series of errors scattered throughout the text Some although minor could be misleading, for example, referring to the Ciliophora as a subphylum and a class on the same page, the invention of a new genus *Campanula* (for *Campanella*) and some erroneous references Although I remain unclear at whom the book is really aimed I can recommend it to all those interested in ciliates since it does make a useful addition to the small but rapidly growing set of books dedicated to protozoological topics COLIN R CURDS

Dying of cold

Temperature and Life By H Precht, J Christophersen, H Hensel and W Larcher Pp xx+779 (Springer-Verlag Berlin and New York, 1974) DM 142, $58 30

Effects of Temperature on Ectothermic Organisms: Ecological Implications and Mechanisms of Compensation Edited by Wolfgang Weiser Pp xi+298 (Springer-Verlag Berlin and New York, 1974) DM 66, $23 10

TEMPERATURE is one of the most important and easily measured environmental influences affecting living organisms Many aspects of physiology are best understood in terms of reactions to stress and, of the various factors causing stress, temperature is, perhaps, the one most often encountered Study of thermoregulation has contributed much to the concept of control theory in biology by the same token, investigation of thermal adjustment in ectothermal animals is likely to have far-reaching influence on ideas about the regulation of metabolism in general For reasons such as these, various aspects of thermobiology are today being studied extensively, with the result that new books and review articles are constantly appearing The volumes under review are the latest on the subject to appear

The first is a revised and updated English version of *Temperatur und Leben* by Precht, Christophersen and Hensel, first published in 1955 Although constructed along the same lines as its predecessor, it differs in that the number of contributors has been increased to include two microbiologists, one biochemist, seven botanists, three zoophysiologists and three human physiologists An attempt is made to treat as many problems as possible, but the main theme remains the adaptation of organisms to changing temperatures A supplementary volume on physical and chemical aspects by L Lumper, is to be published later A special effort has avowedly been made to cover, often in the form of footnotes, the copious literature that has appeared since 1955 To judge by those particular fields with which I am familiar, however, it would seem unlikely that more than about one tenth, at most, of significant contributions has been included Even so, a rather turgid compendium has been produced, probably of use to research workers for reference purposes rather than for stimulation, whose detail at the same time far exceeds the requirements of most graduate students

The various chapters have been grouped under the headings of poikilothermic organisms (microorganisms, plants, animals) and homeothermic organisms In my view there is no clear distinction between homeothermy and poikilothermy, so the classification adopted tends to obscure the relationship between homeothermy and size in animals With an unfavourable surface to volume ratio, the maintenance of a constant body temperature would be economically unacceptable for small organisms

Temperature and Life shows little evidence of the meticulous planning that clearly went into its nearest competitors such as *Temperature Regulation in Mammals and other Vertebrates* by J Bligh, (Elsevier, North-Holland Amsterdam, 1973), *Cryobiology* edited by H T Merryman (Academic Press London and New York, 1966), *Thermobiology* edited by A H Rose (Academic Press London and New York, 1967), and *Comparative Physiology of Thermoregulation*, vols 1–3, edited by G C Whittow (Academic Press New York and London, 1970, 71, 73) Of course, none of these covers quite such a wide field as the new book, although their design is far better Indeed, herein lies the nub of my criticism The study of temperature and life has long since passed the point at which it can be reviewed comprehensively in a single volume—even one of 779 pages with fine type

Wolfgang Wieser's book likewise suffers from the fact that it possesses little intrinstic homogeneity This, however, is probably unavoidable, since it represents the proceedings of a symposium held at Obergurgl, Austria, from September 4–8, 1972, at which only a restricted number of topics was covered The 25 contributions are grouped under three headings mechanisms, ecology and cold resistance but, within these broad classifications there is often little in common between one paper and the next There is also very considerable variation in quality An opening review by the editor stresses the complex "multistable system" from which the answer best suited to the prevailing or anticipated thermal régime is called into action by changes in ambient temperature This farsighted approach may well provide the kind of stimulus lacking from *Temperature and Life*

Despite the vast amount of data reviewed in both books, it is evident that knowledge of thermobiology is still superficial To cite a few examples, the mechanisms by which death results from heat or cold are very imperfectly understood They are certainly diverse, and are complicated by the fact that unrelated mechanisms within an organism may be influenced concurrently in different ways Extremes of temperature may denature enzymes, or liquify membrane lipids The injurious action of heat may also damage mitochondria, affect the coding of proteins, impair the coordination of physiological processes, disturb the functioning of endocrine glands and neurosecretion, and engender the accumulation of harmful metabolic products or an inadequacy in the transport and supply of oxygen The harmful effects of cold are equally multiple Again, little is known of the neurophysiology or mode of function of thermal receptors in animals, nor why long-term adaptation has so little effect on the properties of these sense organs It would be misleading to lump together a number of unrelated phenomena merely because they are engendered by the same thermal influence one must therefore accept the fact that no unitary explanation exists

The indexes of both volumes are restricted to subject only the titles are omitted from references cited in the first Since these number well over 4,000 this defect is, no doubt, unavoidable

J L CLOUDSLEY-THOMPSON

Systematic archaeology

Kalambo Falls Prehistoric Site Vol 2 The Later Prehistoric Cultures By Desmond J Clark With contributions by B M Fagan, M R Kleindienst and F van Noten Pp xiv+420 (Cambridge University London, February 1974) £17, $49 50

THIS is the second volume of Professor Clark's report on the archaeological sites at Kalambo Falls on the borders of Zambia and Tanzania The first covered geology, palaeoecology and stratigraphy (reviewed *Nature,* **223,** 326, 1969), the second covers the upper part of the archaeological sequence, from the Iron Age back to the Second Intermediate, about 7600 BC The third volume, still in preparation, will cover the earlier periods, ranging in date from about 25000 BC to more than 60000 BP Both published volumes reflect the modern standards required for excavation reports Very careful excavation of a number of sites has produced a remarkable range of information particularly in the environmental field, further, a number of carbon-14 dates have been obtained covering a long period, dates which are much needed in African prehistory

The upper part of the archaeological sequence, the Iron Age, covers a time span from about AD 345 to AD 1580, the last date apparently being that of the foundation of the modern settlement in the district This continuity of occupation is discussed in chapter 1, where the history of the recent Bantu settlers is dealt with in some detail Chapters 2 and 3 cover the Iron Age settlements and chapters 4 to 7 inclusive the two Stone Age complexes which precede them

The latest of these Stone Age industries has carbon-14 dates of around 1950 BC and belongs to the "Late Stone Age" of southern Africa Like many complexes grouped under this heading the Kaposwa, as Clark calls this material, is characterised by an abundance of microlithic tools, mostly crescents and triangles This Kaposwa has been compared with a number of sites in Zambia, Malawi and further south which are within the same time range and which have a comparable industry, some of these seem to be as early as 10000 BC, similar in age to the early postglacial industries in Europe The trend towards microlithic tools continued in parts of South Africa into early colonial times among groups which had retained a strictly hunting and food-gathering economy

Clark named the other stone age industry Polungu It belongs to a phase which in southern Africa is referred to as the Second Intermediate, a stage between the Middle Stone Age with industries based on a flake technology and the frequent use of prepared cores, and the Late Stone Age with microliths and a blade technology like the Kaposwa The Polungu from Kalambo Falls comes from two stratigraphic units So far only the earlier has produced a carbon-14 date, about 7600 BC —towards the end of the time range for these industries which probably go back to about 1600 BC This period was within the Late Glacial in Europe

Both Kaposwa and Polungu differ in some respects from other Second Intermediate industries, not surprisingly considering the time and distance separating them The Second Intermediate industries do, however, make a fairly homogeneous group

Clark treats all three complexes in great detail with a minute statistical breakdown and a discussion of each in relation to its place in the African sequence, thus providing an informative summary of later African prehistory He has also given a great deal of space to his own views on classification so his terminology is clear Every ounce of information possible has been extracted from the excavation and presented in a very systematic manner with an excellent standard of book production I have only very trivial complaints plate 98 seems of little value and the caption of plate 97 could have been a little clearer

J WAECHTER

Biology called to account

The Scientific Conscience Reflections on the Modern Biologist and Humanism By Catherine Roberts Pp xii+130 (Centaur Fontwell, Sussex, July 1974) £2 50

MANY people have uncomfortable feelings of moral ambivalence when they consider the aims, practices and ideas of much current science, and particularly of the self-styled "new biology" The leading figures in this domain may be admired or envied for their energy, cleverness, and social success, but few would look to them as exemplars of the primary human virtues The modesty of a Darwin, the personal courage of a J B S Haldane, the altruism of an A R Wallace, the sense of public responsibility of a Pasteur, or the dedicated persistence in the face of poverty or ill health or both, displayed by many humble naturalists of the last century, are all qualities hard to match among the biological celebrities of our day It is scarcely accidental that several recently published books on the philosophy of biology make no reference to ethics at all, but treat science as an entirely autonomous domain The moving spirit of modern biology has a decided resemblance to that Mephistopheles who in the prologue to Goethe's "Faust" presented himself before God in true Popperian fashion as "the spirit that denies", and later in the play was constantly urging Faust to "the effecting of all things possible" by demonic aid

Dr Catherine Roberts, a microbiologist turned to classical Greek studies and philosophy, has gathered together a number of essays, the chief unifying factor among which is that they are all directed against various aspects of the Mephistophelean spirit in modern biology The latest of the essays dates from 1966, so that we do not have Dr Roberts's reactions to *The Double Helix* of J D Watson, which might have been interesting Her own standpoint, nowhere clearly stated in this book, would seem to be a form of neo-Platonism like that of Kathleen Raine, and very definitely committed to the cause of God as against Mephistopheles Her basic attack is directed against the whole concept of science as a completely autonomous activity Despite the title, her argument implies that there cannot really be such a thing as a 'scientific' conscience, if we make moral judgments and valuations, we cannot do this quâ scientists, but only in what she considers to be our higher capacity as fully human beings

The essays are essentially separate, and inevitably somewhat overlapping, they express, at times with some eloquence, a consistent point of view, and one which is likely to gain more adherents in future, but do not attempt a systematic intellectual exposition of it—for this, with engaging modesty, Dr Roberts refers her readers to Michael Polanyi's well known *Personal Knowledge* (1958) The whole book has what used to be thought of as a 'feminine' quality, basing itself more on an appeal to the heart than on coercive rationalisation Her opponents will doubtless deny the validity of any such appeal, and take credit for their own heartlessness We may well wonder for how long it will be possible for such people to pursue ambitious scientific careers, financed at the expense of taxpayers, half of them women, and most of them with old fashioned human hearts

R A CROWSON

Microbes and men

Microbes and Men Producer Peter Goodchild BBC2, Wednesday 9 55 pm

FOR their newest medical/scientific effort, BBC television have homed in on four of the founding fathers of modern medicine and bacteriology, and by means of carefully reconstructed dramatised documentary have tried to tell it as it was Unfortunately, in the process they have failed to enliven these undoubtedly fascinating characters, Semmelweis, Pasteur, Koch and Ehrlich

Locations, medical instruments, crucial experiments and the appalling conditions in hospitals at that time are painstakingly reconstructed, and the commentary linking the episodes of dramatic action is lucid, informative and accurate They have foregone the image of the great scientist and have faithfully documented the petty squabbles, the failures and the obtusenesses as well as the brilliant insights and triumphs

The fact that in spite of all this the programmes never come alive may be a fault inherent in the presentation itself Patches of dramatic dialogue are interspersed with the commentary, which although necessary to convey all the hard facts and point the moral in the 55 minutes allowed for each episode, throws an air of unreality over the whole proceedings, especially as the marriage of commentary to picture is sometimes heavy-handed

The first programme of the series, on the Hungarian doctor Ignatz Semmelweis, screened this week, may, in fact, be the best Semmelweis was an exceedingly complex character, especially in his failure to follow up his brilliant work on the origins and transmission of puerperal fever, a disease which killed one in three women in childbirth in the 19th century lying-in hospitals As one character says to Semmelweis' wife in the 'authentic' context of the cosy drawing room, "Science is moving, and I want to make sure he doesn't get left behind" The programmes are in fact littered with this sort of aphorism, usually delivered in ringing tones The overall effect, for all its undoubted authenticity, is remarkably reminiscent of the great 'lives of the composers' *genre* of films

The BBC have seen fit to screen the series relatively late in the evening although the programmes would be eminently suitable for children and would probably be much enjoyed by them Perhaps the BBC thought that the blood and gore, especially in the first episode might be off-putting, but children are usually far more resistant than the adult audience for whom it is obviously intended

A book of the series (*Microbes and Men*, £2 50) will be available next month

ELEANOR LAWRENCE

obituary

H. Taylor

SIR HUGH TAYLOR, former graduate school dean and chairman of the chemistry department at Princeton University for 25 years, died at Princeton on April 17, 1974 at the age of 84

Born in St Helens, Lancashire, he received his University training at Liverpool under the tutelage of Sir Frederick Donnan, graduating in 1909 and earning a masters degree in 1910 In 1912 and 1913 he studied reaction kinetics, the first year at the Nobel Institute at Stockholm with Svante Arrhenius and the second with Max Bodenstein at Hanover Technische Hochschule In 1914 he was awarded a doctorate at the University of Liverpool He went from there to Princeton University, where he spent the rest of his life except for two years during the First World War when he worked in the United Kingdom

In Princeton, Taylor progressed rapidly through the early professional grades becoming a professor in 1922 and Chairman of the Department of Chemistry by the time he was 36 He served in this capacity from 1926 to 1951 He also served with distinction as Dean of the Graduate School from 1945 to 1958 A person as effective as Sir Hugh has no opportunity to retire After 1958 he continued his dedicated interest in graduate education serving as the first president of the Woodrow Wilson National Fellowship Foundation, the Princeton-based foundation supporting quality in higher education

Sir Hugh's influence on kinetics has been felt worldwide, especially as applied to catalysis which is a theme running through his 300 scientific papers and his books The book he wrote with E K Rideal *Catalysis in Theory and Practice* published in 1919 grew out of work by the authors in Britain during the First World War and was widely used His contributions to photochemistry, radiochemistry and chemical kinetics were likewise fundamental During the Second World War, his pioneering efforts in preparing heavy water and diffusion barriers were of great importance to the atomic bomb project

No picture of Sir Hugh would be complete which left out his generosity, his intense vigour and his decisiveness He usually emerged from his office just slightly slower than running In the seminars which he presided over so superbly, no one could present more quickly and clearly the gist of the problem at hand and place it in proper perspective With this went a warm enthusiasm and an appreciation of good work by others that made reaction kinetics, and chemistry in general, blossom profitably at Princeton

Erratum

In the article "Activation of suppressor T cells by tumour cells and specific antibody" by R K Gershon *et al* (*Nature*, **250**, 594, 1974) the end of one sentence and the beginning of the next were inadvertently omitted from the penultimate paragraph The third and fourth sentences of that paragraph should read 'It is well known that the immunogenicity of antigen is highly dependent on the physical state in which it is administered[19] Antibody can affect the physical stage of antigen[20] and in so doing, perhaps, change the T cell response to it'

Going on about race

CONSTANT LAMBERT was an opinionated but highly readable commentator on the musical scene of the 1920s and 30s, of which he himself was a part. In *Music Ho! A Study of Music in Decline*, he wrote thus of Russian symphonic music based on folk origins—'. . . the whole trouble with a folk song is that once you have played it through there is nothing much you can do except play it over again and play it rather louder!' The conflict between those who see a genetic component in white/black IQ differences, and those who do not runs some risk of becoming in science what the folk song became in symphonic music. The latest action replay of the controversy was performed in London last week at the Institute of Biology's seminar on Racial Variation in Man.

The conflict is actually a three-cornered affair between those who say 'nature' dominates, those who say 'nurture' dominates, and those who cry racism. These last who vilify the 'nature' proponents as racists—and they managed a modest demonstration outside the hall last week—should be aware of some dangerous pitfalls.

- It is no good simply decrying the IQ test as such. There is no doubt a substantial degree of disaffection with IQ as a valuable measure of anything useful. Fun can be poked at the skills which it seems to encompass; much can be made of the success of those with modest IQs, and the failures of those with astronomical ones; it can be accused of dividing children at too early an age into sheep and goats, but the fact remains that it is a widely used measuring rod. Further, as Professor Thoday put it in *Nature* last year, 'concerning within-group differences . . . relative performance in IQ tests correlates with relative performance in aspects of education that are highly relevant to success in, and the needs of, modern societies.'

- It is no good denying the existence at present of between-group differences in mean IQ. They are real and it serves no useful purpose to pretend that they are the result of errors of measurement or that they are trivial.

- Lionisation of those who have found a low degree of heritability of IQ is wishful thinking and an utterly unscientific approach. It would do the cause of social responsibility no good to be wedded to an attractive but maybe wrong conclusion.

In short, catch phrases such as 'Smash the racist IQ test' and 'Nurture not nature' are no way to approach the problem. But problem there is. It is difficult to escape the conclusion that those who go on saying that heritability is high are feeding racist tendencies, however inadvertently and seemingly innocently, and are supplying an apparent scientific basis for those who wish to justify racial discrimination. Many scientists would, of course, contend that the evidence on which the present debate is being conducted is not such as could correctly be termed scientific, but the general public, unlikely to appreciate the finer points of the internal squabbles of science, will in the end absorb the message that is repeated most frequently and with the most crescendo.

Educational policy-makers may then be under considerable pressure to introduce some sort of *apartheid* system which tries to partition off by racial group in the interests of uniformity. However neat and justifiable such a system might seem on the face of it, it would be going in the wrong direction in two distinct ways: the educational experience should be more than just intellectual pump-priming, it should now more than ever help to reduce societal divisions; and to educate on the basis of group membership rather than individual capability is to waste the diversity of talent which sometimes seems the main asset of society.

The scientist faced with a discovery which is controversial and maybe unpalatable to some has an awesome responsibility to handle it correctly, and he should be prepared if necessary to devote the rest of his scientific life to ensuring that the proper use is made of the discovery. Would racial segregation in education be a proper use for apparent high heritability of IQ?

It is simply not possible, having unearthed a potentially explosive piece of information to sit on the fence in the name of scientific objectivity. Those who do not take every opportunity to minimise the risk of the subsequent explosion are actually helping it to come about. And those who keep raising the inflammatory issue must be presumed to want to speed the explosion.

A hundred years ago

Mist Bows

ON Sept. 14 I was driving from the Lizard just after sunrise with Mr. Lugg of Manaccan. A thick mist covered the fields and moorland. The tops of the farm buildings and corn stacks and the church towers were visible above the sea of mist which, matted on the ground, gave the entire country the appearance of being covered with snow. About 6.30 A.M. the sun was bright on our right hand, and on the left we saw a halo of prismatic colours forming a distinct circle of rainbow at a little distance from and encircling the shadows of our heads, and only broken where the shadows of our bodies interposed. This appearance lasted for ten minutes, and our shadows with their attendant bow showed brightly against the mist background as we passed hedges and fields, and kept pace with us like "the mist raised from the plashy earth" by the hare in Wordsworth's poem,

"That, glittering in the sun,
Runs with her all the way wherever she doth run."

We afterwards opened a valley terminating in an extensive moor, when the mist appeared as a sea of prismatic colour extending to the horizon. About 7 A.M. we saw a perfect bow free from any prismatic colour, both ends of which terminated in the field immediately to our left.

My companion, who is constantly driving about this district in early morning, says he never before saw similar phenomena.

Lizard Signal Station, Sept. 16 HOWARD FOX

From *Nature*, **10**, 438, October 1, 1874.

Towards a European Space Agency

SINCE April 1 this year we have awaited the establishment of the European Space Agency (ESA). The new single organisation will take over the functions of the three existing bodies—ESRO, ELDO and the ESC*—to become the NASA of Western Europe. ESA will be responsible for running not only the scientific and application satellite programmes of ESRO but also the three new ventures decided a year ago by ten European space nations—the Spacelab orbital laboratory, the Ariane launcher and the Marots maritime satellite. Each of these three new programmes will be developed under the respective sponsorship of Germany, France and the UK. The rules of participation in the programmes will also be changed by the new convention of ESA. As before, a participating country will have work allocated to it by the Agency in proportion to the amount of cash it subscribes. But now member-states will also have the right to contribute such sums as they feel necessary, and to opt out of specific Agency programmes which they don't find attractive.

The creation of ESA has been progressively delayed throughout this year. The ten European ministers will meet again this week in Paris, but a French government source said last week that there would be no decision until mid-October. Indeed, it is absolutely impossible to foresee what could happen next month. There may be another postponement, but it is hoped that ESA should be settled before the end of the year.

The delay is caused by a fight for the leadership of ESA between the two most important contributing countries. France and Germany have both proposed a candidate as first general manager of the organisation. France is also trying to obtain the participation of the other member states to the cost of the French Guiana Space Centre, which became the launching range for the Ariane rockets. Unexpected events like the sudden death of President Georges Pompidou and the following election campaign have also contributed to the delay.

The new French government hasn't decided much about space affairs—apart from signing the Memorandum of Understanding for the joint development of the Aerosat satellites by Europe and the United States.

On current thinking, the French government should define its space policy in early October at a special council of the ministers concerned. Some official sources say it will closely analyse the space report, and the Ariane project will certainly be questioned. The former government always thought that the heavy launcher was to be "the keystone of the European space policy", considering the political and economical value of the application satellites. More than 3,500 million francs have been spent to duplicate the US heavy rocket that failed when the Europa 2 rocket blew up in the Atlantic. Now France and Germany require an American launcher to put the Symphonie communications satellite into orbit in December of this year. But the US State Department imposed such limitations to the use of this experimental satellite that its interest will be significantly reduced.

Now comes the second and decisive stage for the European rocket. In May, 1973, France proposed to jump a step with Ariane, a more powerful launcher able to place a 750 kg payload into geostationary orbit, which could be developed before the end of the decade. France picked up at least 65% of Ariane costs, which are currently budgeted at about 2,500 million francs for the development only. Ten European countries, including the U.K., are participating in this programme. Tooling up, long-term supplies and engine ground testing are now under way, and the industrial team has been selected recently.

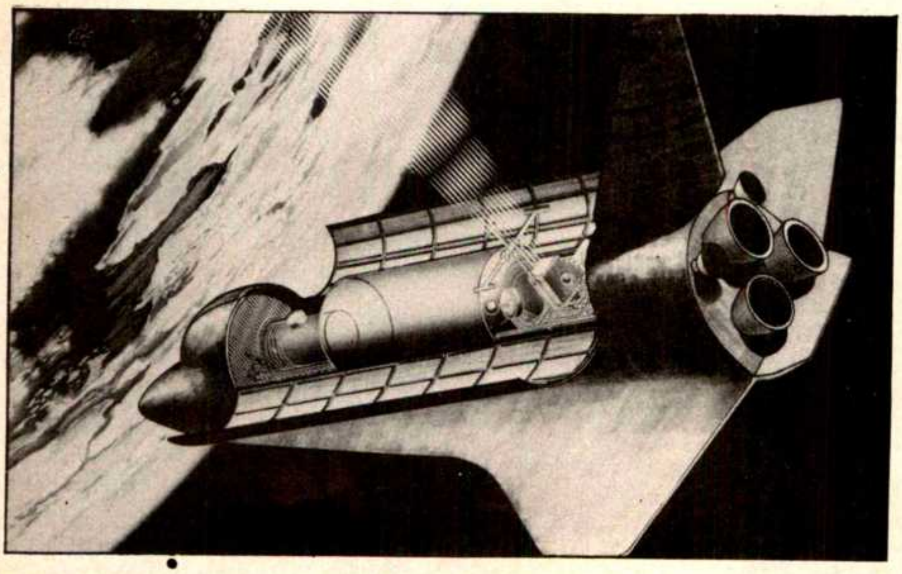
Meanwhile, last June, the French government withheld authorisation for the Centre National d'Etudes Spatiales (the technical and financial manager of Ariane) to conclude the long-term contracts of development with the main contractors. The government needs to think carefully before acting because the programme necessitates more and more spending during the next three years at the same time as the other European space activities also begin to be more costly. In spite of all these new expenses the government don't want to increase the space budget; recent reports from the French Ministry of Industry are very clear about this. In such circumstances the CNES may be obliged to reduce, postpone or even to cancel some of its activities although usually France considers that European expenses take priority.

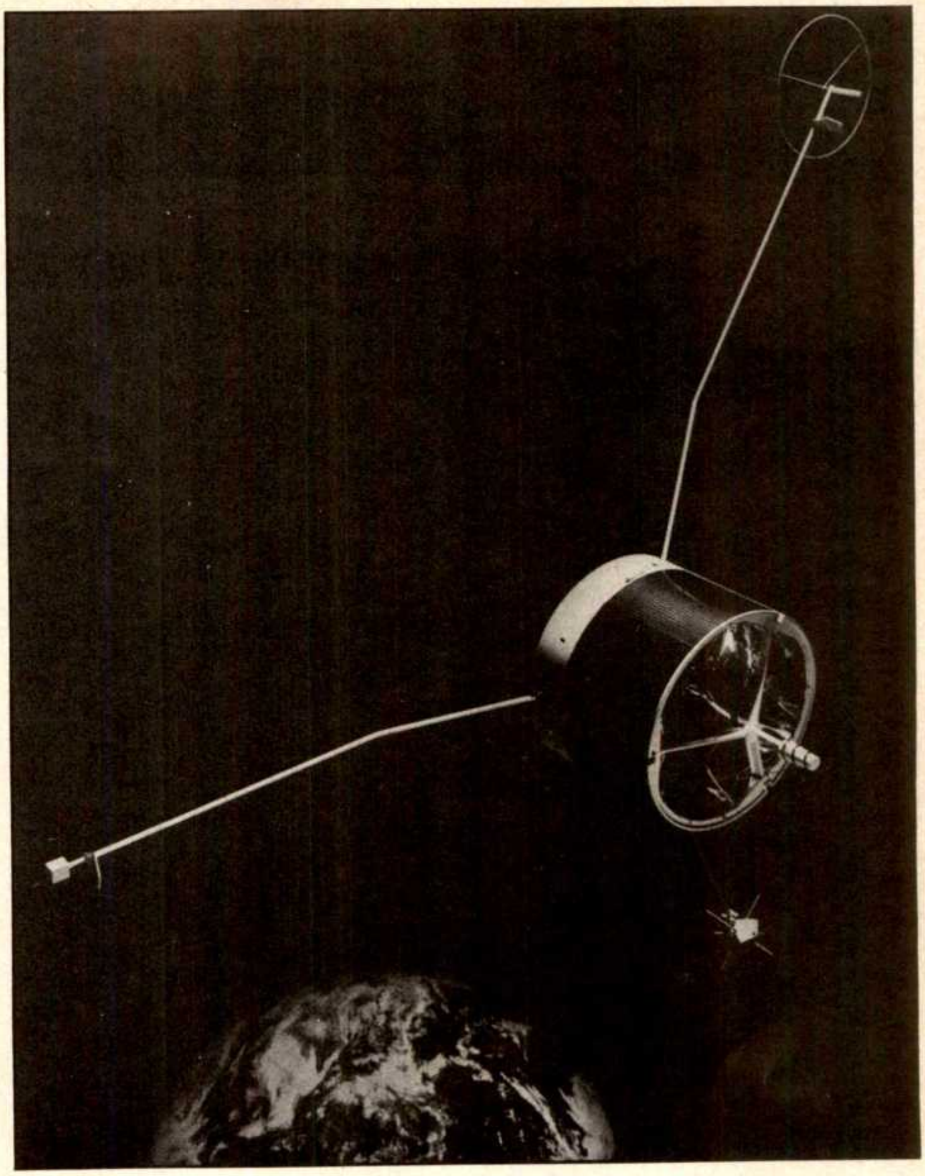
Nevertheless, the Ariane programme could be in danger. The 200-ton three-stage launcher will be the largest rocket built in Europe. But it will be relatively expensive and its market seems less important than expected. A joint study by French and Germans anticipated 35 to 50 launches in ten years (1980–90). But it was never published, and the specifications for the launch range consider only two firings per year during the same period, i.e. less than half the forecast.

The real reason for the difficulties is a political, economical and cultural one: the French desire to build "the launcher of European independence". But it is not certain that the new government will follow its predecessor on this policy. President Valery Giscard d'Estaing has based his policy on change, and on the evidence of the past three months he has a habit of making surprising decisions. For the present government to drop the idea of backing the launcher would be the worst thing possible for the French aerospace industry.

Despite these troubles, the other programmes are running well. Spacelab, which will also be a long-term develop-

Spacelab: first flight planned for 1980.





International Magnetospheric Explorer (IME): to be placed in orbit in 1977.

ment with significant spendings, is going on. This 400 million dollar programme will be a truly international space venture under the leadership of Europe. Developed by 10 countries—all 10 members of ESRO except Sweden but with Austria—the Spacelab will be a part of NASA Space Shuttle Transportation System. European industrial and technical teams are in permanent contact with NASA officials over the development of this spacecraft, which will be completely dependent on the Space Shuttle Orbiter.

It is a versatile manned space laboratory in which scientists and engineers with only a short training as astronauts will be able to live and work for periods of one week to one month in weightlessness. The crew will perform different tasks: scientific missions, Earth resources and weather surveys, communications and other technology experiments. The orbital laboratory has two main parts: a pressurised module connected by an airlock to the Orbiter crew cabin and a pallet which supports instruments exposed to the vacuum of space.

NASA has ordered two Spacelabs from ESRO. The first flight of Spacelab is planned for April 1980, with the seventh flight of the Shuttle, on a mission not yet defined. More than 200 experiment proposals have already been received by ESRO from the European scientific community for this flight.

The next two European scientific satellites will be in space within a year. The COS-B satellite will be launched in April or May 1975 to study gamma rays, and the GEOS satellite will be put into the geostationary orbit in September, 1976, to investigate plasma distribution, energetic particles and electromagnetic fields.

In December, 1976, NASA will launch the International Ultraviolet Explorer satellite (IUE), a joint US-UK project in which ESRO participates. The next project will also be a cooperative one between NASA and ESRO. The ISEE satellite (formerly IME-D) is due for launch in September, 1977, with a brother American satellite from the same launcher to study the magnetosphere. For mid-1979, ESRO is preparaing the highly eccentric lunar occultation satellite (EXOSAT) that will map the X-ray sources.

Since 1970 13 scientific mission proposals have been submitted to ESRO, but only one or two will be retained in early 1976 for development. All these missions could be realised with the Spacelab or free flyer satellites. Two-thirds of them are cooperative projects with NASA. Nine are devoted to infrared, ultraviolet and X radiation studies of the Sun and the sky. Three others are more impressive projects including the first probe to make observations from out of the plane of the ecliptic.

There is also a Pioneer–Jupiter orbiter probe and the interception of Comet Encke by the end of 1980 to proceed with the first close study of thesem ysterious space objects. Another proposal is an astrometry mission to chart more than 30,000 stars down to magnitude 17 with a precision 10 times better than the existing references. The feasibility of this project will be discussed at a special colloquium to be held next month at Frascati (Italy).

Among the application programmes, the meteorological satellite (Meteosat) will be put into geosynchronous orbit in December, 1976, to participate in the Global Atmospheric Research Program of the World Weather Watch. Three other experimental satellites are due for launch close to the end of 1977 to prepare the operational systems of the 1980s. The OTS satellite will pave the way for the European Communications Satellite (ECS) designed to provide space links for intra-European telephony, telegraphy, telex and TV relay for the European Broadcasting Union. The aeronautical satellite (Aerosat) will be the first step towards a world-wide air traffic control and communications satellite system. And the maritime satellite (Marots) will carry out experiments involving communications between ground and merchant ships to prepare the future IMCO operational system to cover the seas and the oceans of Earth. All these new European satellites—like the seven built over 10 years by ESRO—will be launched by American rockets from the United States.

*ESRO is the European Space Research Organisation; ELDO is the European Launcher Development Organisation formerly responsible for the launcher Europa 2, and ESC is the European Space Conference, i.e. the forum for decisions by the European science ministers.

international news

Fruits of a Faustian bargain

by Colin Norman, Washington

Charles Colson, former President Nixon's one-time hatchet man, announced soon after the 1972 election that the Administration would take no vindictive action against those who had the temerity to oppose it. In fact, said Colson, a large federal programme was already in the works for the only state which had cast its votes for McGovern—a nuclear waste repository would be built in Harvard Square.

Fortunately, even though members of the infamous White House enemies list were heavily concentrated in the Boston area, Massachusetts won't be so lucky. That particular federal programme will go to Nevada, Idaho or Washington state.

Last week, the Atomic Energy Commission announced that sites in those three states have been shortlisted as potential locations for a temporary storage facility where highly radioactive waste material from nuclear power stations will be kept under surveillance until a safe, proven method is found to get rid of the stuff. The agency also acknowledged that it has yet to find such a method.

The announcements and acknowledgements were contained in an unusual document—an environmental impact statement in which the AEC, instead of analysing the consequences of a single, chosen programme, has floated some ideas, asked for comments on them, and said that it will take the comments into account when it makes its final choice.

Although that piece of before-the-act public consultation has been welcomed by the AEC's friends and foes alike, it will, nevertheless, do little to dampen the fierce debate over nuclear waste disposal which has been going on in the United States for several years. But it should at least help to sharpen the issues. For those who have tuned in late, a little background is in order.

The waste material in questions consists of radioactive isotopes formed in a reactor core from uranium fission. When irradiated fuel rods are removed from the reactor they contain not only unwanted isotopes such as strontium-90 and cesium-137, but also large quantities of plutonium and unused uranium which are so valuable that they are removed in a reprocessing plant and later reused as reactor fuel.

What is left is an acidic solution of waste material which contains virtually all the radioactivity from the spent reactor fuel and which must, somehow, be disposed of. Since such solutions are not the easiest things to store—in fact, there have been some serious leakages from storage tanks at AEC facilities in Washington and Georgia—the AEC began a programme in the 1950s aimed at finding a method of reducing the waste solutions to stable solids.

A method has been developed which essentially consists of depositing oxides of the unwanted isotopes on granules of aluminium oxide, and in 1970 the AEC issued a regulation which requires that all highly radioactive wastes from commercial power stations be solidified and sealed into steel canisters before being shipped to a federal nuclear waste repository.

The problem, though, is that no such repository yet exists because the AEC has had considerable trouble finding a suitable dumping ground. The trouble stems from the fact that because the reactor wastes contain extremely long-lived radioactive isotopes which will remain highly dangerous for several centuries, they must be kept isolated from the environment for thousands of years.

The most promising disposal method, according to virtually every committee and commission which has studied the matter—including the National Academy of Sciences—is to bury the waste canisters in bedded salt, which is geologically stable, provides an effective radiation shield, and is unlikely to be in contact with subsurface water.

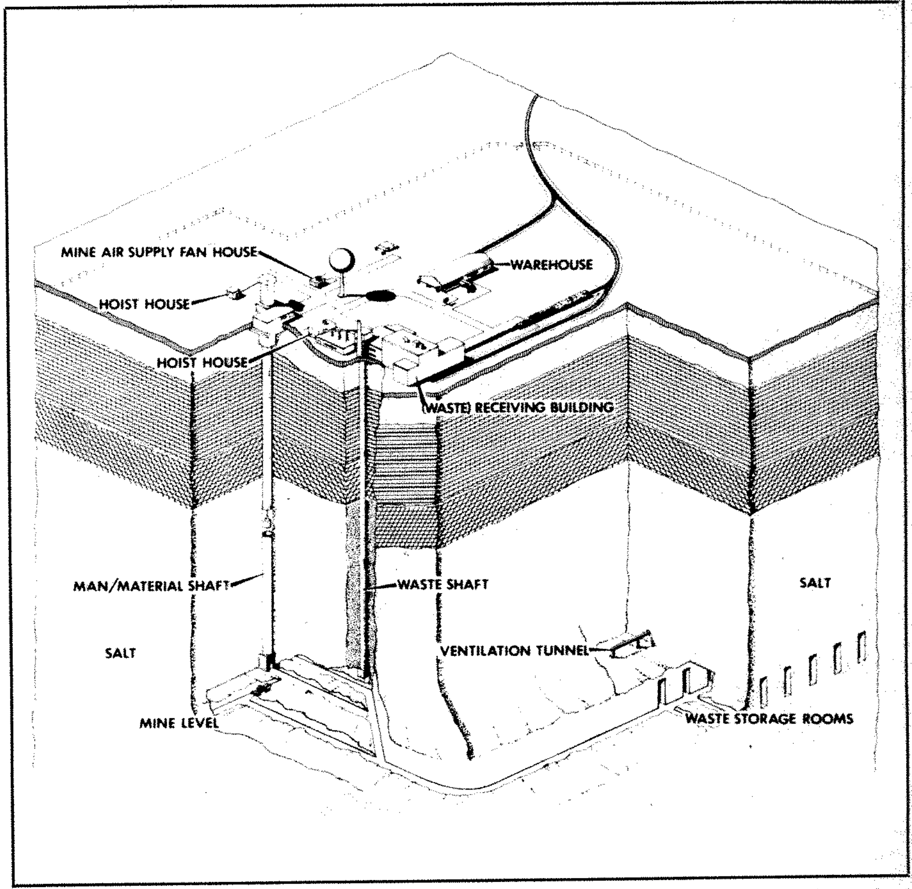
During the 1960s, the AEC found what looked like an ideal site—a disused salt mine near Lyons, Kansas—and in 1971 the agency asked Congress for funds to conduct pilot-scale operations there with a view to turning the mine into a federal repository if all went well. Fortunately, though, the project met with political opposition, Congress denied the funds and it later turned out that the area was, as one Kansas state engineer put it, "like a piece of Swiss cheese". Back to square one. Then, in 1972, the AEC announced that it was going to buy some time by constructing a storage facility above the ground in which wastes could be kept under constant surveillance while a search is made for a permanent disposal site. And that, essentially, is where last week's environmental impact statement comes in, for the AEC has now not only shortlisted potential sites, but it is also close to choosing a design for the storage facility.

In the meantime, however, critics of nuclear power have seized upon the AEC's difficulties and turned them into a potent argument against the burgeoning growth of nuclear generating capacity. They have argued that it is immoral and unwise to push ahead with a technology which will leave a dangerous legacy for many generations. The nuclear power programme should therefore be halted at least until a safe waste disposal method is found and tested. Needless to say, the AEC does not agree.

According to the environmental impact statement, the above ground storage facility will be capable, if necessary, of maintaining waste canisters safely for "at least 100 years", although, with luck, that will not be necessary for the AEC hopes to have found, tested and prepared a permanent disposal site within two or three decades.

The AEC's strategy, as outlined in the environmental impact statement, is this: It will probably choose a design and a location for the storage facility in the next few months, perhaps even in time to ask Congress for construction funds in the 1976 fiscal year budget. The facility should be ready to receive its first shipments of waste canisters by 1981, and it will gradually be extended to cope with increasing volumes of wastes towards the end of the century. By the year 2000, in fact, nuclear power stations in the United States will have produced almost a quarter of a million tons of solidified wastes.

In the meantime, the agency will continue searching for a geologically stable burial site where the wastes can be disposed of permanently. Other salt mines in Kansas, and salt and potash deposits in New Mexico are under consideration, and according to Dr Frank K. Pittman, Director of the AEC's Division of Waste Management and Transportation, some pilot-scale tests could begin at one or more potential



Bedded salt pilot plant: most promising disposal method

dumping sites in the 1980s. Pittman added, however, that although he is very hopeful that a suitable site will be found, the AEC has no "implicit faith" that such a site exists.

As for the temporary storage facilities, the environmental impact statement describes three potential designs, each of which has its own advantages and disadvantages. In terms of cost, however, they would work out at about the same—$100 million.

The essential feature of any such repository is that the waste canisters must not only be shielded for radioactivity, but they must also be kept cool because the radioactive decay gives off vast amounts of heat—the temperature at the centre of the waste canister could reach almost 1,000° C. One of the designs would use water as the coolant, while the other two would rely on air cooling.

- The water-cooled design would consist of a series of stainless steel-lined concrete vaults, each capable of holding about 500 canisters and each filled with demineralised water. The water would be kept cool by continuous circulation through a closed loop in which the heat is given up to a secondary cooling loop and dissipated to the atmosphere through a cooling tower. As well as providing cooling, the water also acts as an effective radiation shield, and since it will be constantly monitored for radioactivity, canister leakage can quickly be spotted.

The disadvantage with this design, however, is that it would require large quantities of cooling water, and corrosion may also be a problem over long periods of time.

- One of the two air-cooled storage designs under consideration—the so-called air-cooled vault concept—would consist of a series of large vaults similar to those in the water basin design, each of which would be capable of storing 500 canisters. Each canister would, however, first be sealed in a steel overpack to provide extra protection against the canister rupturing and spewing out its radioactive contents. Cooling would be provided by passive circulation of air through the vault, which would maintain the temperature at the surface of each canister overpack to about 200° C, and the thick vault walls would provide radiation shielding.

The advantage of this design is that there is virtually no possibility of breakdown in the cooling system, but it is the most expensive design and it would disturb large amounts of land.

- The third choice, the sealed cask storage concept, differs from the other two in that no storage vault is required. Each canister would be sealed in a two-inch thick steel cask which would be surrounded by a 38-inch thick concrete shield to provide radiation protection. A six-inch air space between the concrete and the steel cask would allow cooling air to circulate, which would keep the temperature of the cask to about 120° C. The massive concrete storage units would be kept outside, and by the year 2010 the entire storage area could occupy about 1,100 acres of land.

The advantages of this design are, again, that no mechanical cooling system is required, but the disadvantages are the large amounts of land needed and the fact that in the unlikely event of a container rupture some radioactive wastes would be lost to the atmosphere.

The three potential designs are now being looked at by various groups, including a committee of the National Academy of Sciences, and when a final choice is made, the AEC will publish another, more comprehensive environmental impact statement.

The choice of design will, to some extent, also affect the choice of possible site. The AEC has indicated that it is now considering potential sites at the Hanford Reservation in Washington State, the National Reactor Testing Station in Idaho, and the nuclear test site in Nevada. Each of those would be suitable for the two air-cooled designs, but because of the shortage of water the Nevada site would be unsuitable for the water basin design.

In the meantime, the AEC has also been examining a few so-called unconventional waste disposal methods, such as burial in polar ice sheets, placement on the seabed, discharge into volcanoes, or loading the wastes on a rocket and firing them into the Sun. A study conducted by Battelle laboratories has concluded that none of those concepts presents a viable alternative to burial in a stable geological formation such as bedded salt.

Even if the storage facilities will, as the AEC claims, pose little radiation risk to people living close to them—even in the event of the "maximum credible accident" of a canister rupture during storage or handling—the plans outlined in the environmental impact statement are sure to meet with considerable opposition.

For one thing, large numbers of shipments of waste canisters will be required—about 600 a year by 2010—to transfer wastes from reprocessing plants to the storage site. It was, in fact, this aspect which raised most of the opposition in Kansas to the proposed repository at Lyons, and there is no reason to expect that attitudes will change.

But the most powerful argument, which is already being resurrected, is that since there is absolutely no guarantee that a permanent disposal site will be found, the entire nuclear power programme represents a Faustian bargain in which relatively short-term energy benefits have been traded for a very long-term pollution problem. ☐

Court ruling has its dangers

by Colin Norman, Washington

THANKS to a little-noticed ruling of the Federal Appeals Court in Washington DC, research proposals contained in any grant application submitted to the federal government must be disclosed to anybody who asks to see them—including another scientist working in the same field.

Since grant applications, particularly those submitted to the National Institutes of Health, usually contain a fairly detailed description of the proposed experiments and how they will be carried out, several scientists reacted with some alarm when informed of the court decision last week. And, within NIH itself, there is a general feeling that the ruling will affect the way in which grant applications are written and reviewed.

Brought by a public interest law group called the Washington Research Project Inc., the court case itself involved eleven specific grant applications for research into the effects of psychotropic drugs on children with learning disabilities.

A lower court judge ruled in November last year that the Freedom of Information Act (FIA) requires that not only the grant applications but also the reports of peer-review groups which rate them according to their scientific merit, should be made public. The Appeals Court decided last week, however, that while the grant applications should, indeed, be publicly available, the confidentiality of peer-review reports should be preserved.

A fight is now likely to ensue over exactly how the ruling should be interpreted. Although a final determination had not then been reached, government lawyers suggested last week that since the eleven grant applications in question had all been approved and funded by the National Institute of Mental Health, the decision probably does not apply to applications which are still pending. But a lawyer for the Washington Research Project, citing language in the decision which refers to "approved or pending" applications, argues that it does.

In any case, even if the ruling does apply only to approved grants, it would still cause a radical break from established NIH practice and hold some important implications.

First, there is the possibility of plagiarism of research ideas. According to the Appeal Court judge, the government lawyers took "pains to argue that biomedical researchers are really a mean-spirited lot who pursue self-interest as ruthlessly as the Barbary pirates did in their own chosen field". They argued, in fact, that a scientist would be able to get complete details of a competitor's experimental designs simply by asking NIH for them, conducting the experiments himself, and getting into print with the results before the hapless originator of the idea had been able to do so.

There are, however, rather more subtle ways in which the decision could influence the course of scientific research. It has been argued that one result will be that grant applicants will be less than explicit in giving details of their proposed experiments. Not only would that make the job of scientific review committees more difficult, but it could also favour those scientists who have an established track record.

Another possible consequence, cited by the Association of American Medical Colleges in a court brief, is that "pharmaceutical companies could periodically review NIH and NIMH files for the purpose of converting research findings to commercial use, thereby converting the government into a conduit of free research and methodologies for private gain". Furthermore, sinc the drug companies would also be made aware of what research the government is funding, they would be less inclined to invest in those areas, "thus discouraging independent biomedical research", the AAMC argues.

On the other side of the coin, however, it can be argued that taxpayers have a right to know exactly how the federal government is spending their money, and it would be contrary to the spirit of open government embodied in the Freedom of Information Act to keep research applications confidential.

Be that as it may, the government will probably appeal the case to the Supreme Court, although no decision has yet been made on that score. Alternatively, Congress could attach an amendment either to the Freedom of Information Act, or to other legislation such as appropriations bills, to preserve the confidentiality of grant applications. A move by Senator Robert Dole earlier this year to attach just such an amendment to the Freedom of Information Act was, however, turned back pending the court decision, and Congress is, in any case, unlikely to pass such a measure without first giving it some study at the committee level. □

Israeli jobs for Soviet scientists

from Nechemia Meyers, Rehovot

WILL Israel be able to absorb the 60,000 Jews a year, many of them engineers and scientists, who will reportedly be permitted to leave the U.S.S.R. under the terms of an unpublished agreement between the U.S. government and the Soviet government? To be sure, there is no shortage of jobs in Israel. The building trades, agriculture, industry and various services could absorb thousands of newcomers each year. However, positions are not so readily available for university graduates. Even now, according to Absorption Ministry Director General Menahem Sherman, 1,400 are without immediate prospects of a job.

No one knows how many scientists and engineers will be allowed out, but a large number could appear on the Israeli labour market in a relatively short period of time. Indeed, there are more Jewish scientists and engineers in the Soviet Union—an estimated 100,000—than in Israel, and Israel, of course, has an infinitely smaller economy in which to absorb them.

Israel's National Council for Research and Development has already established a special committee to approve Government allocations to new research units based primarily on immigrant scientists. Groups recently established with NCRD aid include one designed to foster the industrial utilisation of Negev Desert chemicals, another working on tools using radiation for inspection purposes and a third in the field of biomedical engineering.

Dr Vladimir (Ze'ev) Zaretskii (until 1971 a member of the Institute for the Chemistry of Natural Products of the U.S.S.R. Academy of Sciences in Moscow, and now in charge of the Weizmann Institute's Organic Mass Spectrometry Centre) believes that a large number of his former colleagues can be absorbed and help Israel's development at the same time.

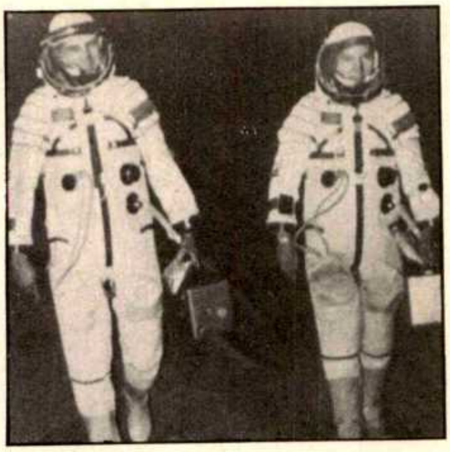
"Their place," he says, "is in industrial research. Thousands upon thousands of talented Jewish scientists and engineers work at centres of applied science. Their talents could be utilised by existing Israeli companies or by specially created new ones."

While welcoming the NCRD bodies, Dr Zaretskii believes an even closer link should be forged between industry on the one hand, and immigrant scientists and engineers on the other. He suggests partnerships that would bring together the research knowhow of the Russians with the business knowhow of Israelis and Americans. "People trained in the U.S.S.R. don't understand Western concepts of profit margins and marketing. But they do know how to work," Zaretskii says.

Certainly this isn't the best time for industrial expansion. Israel's resources are strained to the limit and beyond by defence needs. Moreover, it is becoming increasingly difficult to export goods at a time when world markets are shrinking and country after country is sliding into a recession. □

Soyuz-15: inside information

by John Gribbin



Soyuz–15 crew: could have docked

THE abortive flight of Soyuz-15 provided valuable tests of an automatic docking system intended for use by future "tanker" spacecraft. That at least is the inside story being put about at the Johnson Space Center by Major General Vladimir Shatalov, the Soviet cosmonaut chief (*Aviation Week & Space Technology*, September 16, 22; 1974).

Shatalov has been visiting the Apollo-Soyuz Test Project crew training sessions, and took advantage of the opportunity to give more details of the official Soviet view of Soyuz-15. Confirming that the spacecraft never made physical contact with the space station Salyut 3, he said that the automatic rendezvous system repeatedly took the spacecraft to within 30 to 50 m of the space station, but that the final rendezvous sequence failed each time.

According to Shatalov, docking using manual control would have been possible on any of these occasions. But that was not the purpose of the mission, and the Soviets preferred to spend the available time in repeated tests of the automatic docking system. Time was limited, apparently, because the Soyuz-15 mission was from the outset planned to last only two days, and was intended to land at night to test techniques. Even if docking had been achieved, it seems that the cosmonauts would have undocked and returned—after further docking tests—without entering the Salyut.

The official view is that the flight was a success because it tested the automatic docking system. This system will be needed in future developments of the manned space programme, when "tanker" derivatives of Soyuz will be used in an unmanned configuration to ferry fuel and other supplies up to space stations.

In the USA, there is some scepticism about Shatalov's outline of the Soyuz-15 mission. It is felt very unlikely that two men would have been sent to dock with Salyut-3 without any intention of their entering the space station, and it is also pointed out that the very first docking of two Soviet spacecraft involved unmanned vehicles, and was accomplished seven years ago. Although it seems unlikely that Soyuz difficulties of the kind experienced by Soyuz-15 are related to the joint programme, Senator William Proxmire has expressed concern and says that "present plans for a joint space mission in 1975 should be seriously re-examined in the light of the continuing difficulty in the Soviet program".

But perhaps his fears—and those of others—might be at least partly allayed by two other items of news made public last week. General Shatalov has publicly thanked his US counterpart, Brigadier General Thomas P. Stafford, and US astronauts for not revealing details of Soyuz-14 prior to the launch. It seems that the names of the cosmonauts and the date of launch were known to US astronauts training in the USSR last July, but that at the request of Soviet officials they said nothing to the press "in consideration of Soviet traditions and customs".

That, according to Shatalov, demonstrates the mutual trust needed to make the joint mission work. The other news, however, concerns more tangible preparations. Shatalov has now confirmed that at least one manned mission will be carried out to test Apollo-Soyuz hardware, about two months before the planned date of the joint mission, which is next July. This proving flight can only be carried out by the Soviet team, since NASA only has one Apollo/Saturn vehicle left, to use on the joint mission itself.

300 universities look to the future

from a Correspondent

THE General Assembly of CRE meets once every five years; often enough, it might be thought by those to whom the sight of one Vice-Chancellor is daunting enough, let alone 300. The theme of the Assembly at its meeting recently in Bologna was "The European Universities 1975–1985", and the Assembly divided itself into five groups to discuss particularly the University and the Changing Needs of Society, University Training, University Research, University Government, and the Financing of Universities.

After four half-day sessions the whole Assembly met to hear reports from the five discussion groups. With one or two honourable exceptions, the working papers which had been prepared before the Assembly could only be described as lead balloons, but a combination of good discussion in the groups and excellent work by the chairmen and rapporteurs led to useful and sensible final reports.

The report of the first study group (the University and the Changing Needs of Society) stressed particularly the difficulties that the universities have in responding to the needs of society when those needs are only imperfectly articulated in the present, to say nothing of needs in the future. This made it all the more important that universities, so far as they can, should give not only academic advice to students but should help them with the role they were later to play in society. Since migration in the field of academic professions is growing, an international understanding of the equivalence of diplomas and degrees needed to be established, although the Assembly was very much aware of the danger for the "Third World" of losing some of their best people to the developed countries. While the university should be responsive to society's demands, it should keep constantly before itself its special role as "the place where the most complex and profound work can be done". Perhaps the surprise of this session (at least to Western Europeans) was the "points" system of university entrance practised in Eastern European countries and described by the Rector of Warsaw University, where points could be granted not only to first-generation children of peasant origin but also to winners of sporting events. In Poland and Czechoslovakia, for example, winners of events in national Olympic games are exempted from university entrance examinations.

There was considerable disquiet expressed in the discussion group on University Research about the squeeze on funds for research as financial pressure on universities increased, and how important it was to explain to the public and politicians the essential role of research in universities.

So far as international research projects were concerned, although these were generally to be welcomed, they could be successful only if there was a genuine scholarly need for them. In some cases (and CERN was cited as an example) these projects had been outstandingly successful, but this had not been uniformly the case. Sponsored research was discussed at some length and with enthusiasm. The group felt, however, that there were two basic conditions which must be met by such research: the first was that it must be stipulated that the scientific content of such projects should always be published; the second was that sponsored research should not interfere with the general research policy and the teaching duties of the university.

In the discussions of the financing of universities it was emphasised that, although universities needed to know basic data—such as staff/student ratios, number of square metres/student—for their proper management, these data had to be looked at with an expert eye if they were to be meaningful. There were no strong views about the relative merits of grants or loans for the support of students, but the group was strongly against the notion that undergraduate students, at least, should be salaried and regarded as clients. It was necessary for the university to have strong leadership if it wanted a proper system for setting priorities and wanted to retain proper autonomy.

So, all in all, was their journey really necessary? Most decidedly so, most of the delegates felt at the end. The conference had emphasised once more the strong links which unite European scholarship and the necessity of preserving and nurturing those links.

Adding amino acids

SIR,—The issues that Drs Miller and Payne raise (*Nature*, **251**, 176) may be summarised as follows:

1. No example is available of a field trial that shows measurable benefit of amino acid addition;
2. I confuse the problem of meeting physiological needs for protein with that of aesthetic demands;
3. Methionine, not lysine, is limiting in most diets, including cereal diets;
4. Talk of amino acid fortification constitutes a diversion from the main problem, poverty of large masses;
5. The only solution to the problem of malnutrition is to raise the standard of living and improve traditional agriculture.

It is true that examples of completed field trials are lacking. As I stated, (*Nature*, **248**, 643) some are underway; others might well be started in which non-protein calories (such as cassava, sago, and plaintain, or oil) could be added to a predominantly cereal diet with added amino acids to determine how to extend the range of options for obtaining food energy balanced with protein.

I do not confuse physiological needs and aesthetic demands and stated so clearly in the section entitled "No Substitute for Aesthetics".

That methionine is limiting in cereal diets has been disputed. Bressani and Elias[1] pointed out that only when legume contributes more than 50% of the protein in a cereal-legume mixture is methionine limiting; at that level the diet is not protein-deficient.

The world protein food problem has had an extraordinary history: it is the only major world problem that has been discovered and solved, all within a period of about 25 years, and simply by changing standards. More to the point would be statistics on the prevalence of protein–calorie malnutrition of the kind that indicates a particular deficiency of protein—the kind that was called "kwashiorkor". Has this diminished along with the disappearance of the protein problem? And if, indeed, there is an increase of protein–calorie malnutrition of all types, then does this not emphasise even more the need to provide more food energy and point out the consequences of the protein–calorie trade-off? That amino acid fortification does not reach all elements of a population or that it does not provide additional aesthetics in food is of secondary consequence: the critical point is that additional ways of adding protein make it possible to divert resources to more food energy, or special baby foods, or more pleasing foods.

The world food problem is an extraordinarily complex problem of massive poverty exacerbated by increasing populations and shrinking resources. What Drs Miller and Payne have to offer has been tried again and again, and has been shown inadequate. Only a total world attack can deal with this problem: affluent nations will need to distribute more of their wealth to the poor nations at the cost of a reduction of some aspect of their own quality of life; the poor nations will need to develop policies that reduce the ratio of populations to resources. Ultimately, decisions to act involve moral considerations. But such decisions involve many other factors, among them the availability of solutions and the multiplicity of options. Is it right to deny poor countries the use of technologies that could increase their opportunities to solve problems as they cope with the basic problem of poverty?

AARON M. ALTSCHUL

Washington DC.

Publish it not

SIR,—I am profoundly shocked by the leading article in the issue of *Nature* of September 6. My dismay arises from the content of the fourth and fifth paragraphs. Firstly it seems to me to betray a surprising ignorance of the issue under discussion to draw an analogy with weather modification or shocking experimental animals. In both cases we know the consequences to be localised and if a scientist in Idaho does modify the weather, this has no consequences in India or Iceland. Climatic modification is of course a different issue. But with genome fusions, there is no reason to believe that a blunder might not have consequences which would affect very large numbers of people over a very wide area of the globe.

The second issue relates to your concept of "pushing (papers) into the underground". Certainly there are undergrounds: one is concerned with military research and the other industrial research. But it seems reasonably certain (military matters apart) that the people concerned in this particular field are ones who desire public recognition for their work and who would be discouraged very quickly if they saw that their findings would not lead to the glories of a mention in the Citation Index.

Yours faithfully,
D. W. EWER

news and views

Digesting DNA and chromatin

ALTHOUGH the basic double-helical structure of DNA has been known for many years its sequence arrangements and spatial organisation in chromatin have remained poorly understood The discovery of restriction enzymes, which cleave double-stranded DNA at specific target sites, has given a much needed boost to sequence analysis of DNA Recently some interesting results concerning the organisation of satellite DNAs have been obtained using the restriction enzyme EcoRI, which cleaves DNA at the sequence GAATTC The size of DNA fragments generated by the enzyme reflects the separation of target sites and so a limited base sequence complexity, as exists in satellite DNAs, would tend to result in infrequent cleavage

Botchan *et al* (*Cold Spring Harb Symp quant Biol*, **38**, 383, 1974) found that mouse satellite DNA could be separated from the rest of the DNA by cleavage with EcoRI The satellite DNA formed a slow migrating band on electrophoresis whose fragments ranged in molecular weight from 4×10^6 to 20×10^6, indicating that it is composed of inexact repeating units In contrast, Botchan (in this issue of Nature, page 288) finds that the same enzyme cleaves bovine satellite I DNA into highly repetitious units of 1,400 base pairs Renaturation kinetics indicate that these units are internally repetitious He proposes that two stages were involved in the evolution of satellite I DNA The first stage involved small duplications, indicated by the renaturation rate, to yield the 1,400 base pair unit, and the second stage involved the production of large tandem repeats of this unit Such analysis of other satellites should give a clearer picture of how satellite DNAs are organised and perhaps confirm this hypothesis Mouse satellite DNA, if further analysis does not reveal some higher order of repeating units, may be a case where subsequent divergence has obscured the homogeneity of the tandem arrays

On another level of DNA organisation recent work points to a highly repetitive association of protein with DNA in chromatin Olins and Olins (*Science*, **183**, 330, 1974) reported linear arrays of chromatin particles, which they termed ν bodies, each about 70 Å in diameter They calculated that each ν particle could contain at least one, possibly two, molecule of each of the five main histones and a stretch of DNA of molecular weight between 80,000 and 160,000 Sahasrabuddhe and Van Holde (*J biol Chem*, **249**, 152, 1974) isolated micrococcal nuclease resistant particles constituting 50% of the total DNA from calf thymus chromatin with sedimentation coefficients of between 10S and 12S These particles contained approximately 100 base pairs and had an estimated diameter of about 80 Å Similarly Clark and Felsenfeld (*Biochemistry*, **13**, 3622, 1974) have found that, on digestion with micrococcal nuclease, 50% of the DNA in chromatin remains as protected areas containing roughly 100 base pairs Hewish and Burgoyne (*Biochem biophys Res Commun*, **52**, 504; 1973), on the basis of nuclease digestion studies using an endogenous Ca^{2+}–Mg^{2+} dependent endonuclease of rat liver chromatin, have proposed a simple, basic, repeating structure for chromatin Kornberg (*Science*, **184**, 868, 1974) has elaborated this into a theory of chromatin structure based on a repeating unit containing two each of the main histones (excluding F1 histone) and about 200 base pairs of DNA forming a flexibly jointed chain Support for this theory now comes from the work of Noll (*Nature*, **251**, 249, 1974) who finds that using both the endogenous Ca^{2+}–Mg^{2+} dependent endonuclease and micrococcal nuclease approximately 85% of rat liver chromatin can be digested into 11S fragments containing about 200 base pairs Further digestion, however, causes a breakdown of DNA in these fragments The isolated fragments contain all five major histones and some nonhistone proteins

Thus evidence is accumulating for a regular spatial arrangement of proteins in chromatin, the proteins protecting stretches of DNA from nuclease attack Further studies may show a simple relationship between the 200 and 100 base pair fragments, for example a totally protected 100 base pair unit associated with 100 base pairs which are partially protected T BARRETT

Termination and the juggernaut polymerase

GENE expression seems in general to be controlled at the initiation of transcription An alternative mechanism operates, however, during the development of some phages Initially 'early' genes are transcribed by a host (bacterial) polymerase which is halted by termination signals Subsequently an anti-termination protein is synthesised to allow transcription beyond these signals The mechanisms of termination and of anti-termination have not been well defined and their role within the uninfected bacterium remains particularly unclear Adya, Gottesman and De Crombrugghe (*Proc natn Acad Sci U S A*, **71**, 2534–2538, 1974) now suggest that the mode of termination may be dictated by events taking place at initiation, their work with polar mutants also reveals a new aspect of the connection between translation and transcription

Expression of the galactose operon of *Escherichia coli* is different when caused by readthrough from a prophage instead of the normal initiation at a galactose promotor When prophage lambda is induced, constitutive ('escape') synthesis of the nearby galactose enzymes ensues, for two reasons (1) replication of the galactose structural genes together with the prophage increases the number of operators so that insufficient repressor is present in the cell to prevent transcription, (2) transcription is initiated at the p_l (*sex*) promotor and proceeds from the prophage, through the intervening bacterial genes, into the galactose operon Certain mutations permit only the second mechanism to operate, by preventing the replication and the excision from the chromosome of the prophage

Adya *et al* used an increase in temperature from 32° C to 41° C to induce prophage bearing such mutations They found a seven-fold increase in the specific activity of galactokinase, the enzyme coded by *galK*, the last of the three structural genes of the galactose operon Since the addition of fucose, an inducer of the galactose operon, causes a further increase in galactokinase synthesis, apparently to the same extent as usual, expression by induction and expression by readthrough seem to be additive This suggests that they take place by different mechanisms, and implies that galactose repressor can inhibit only transcription that initiates at the adjacent galactose promotor, and does not act simply by blocking progress of polymerase into the structural genes This is consistent with the observation of Nakanishi *et al* (*J biol Chem*, **248**, 5937–5942, 1973) that repressor and polymerase seem to compete *in vitro* for galactose DNA and also with the dual control noticed in the galactose operon—there appear to be two operator/promotor sites, whose expression is additive but each of whose repression does not prevent expression from the other (see Hua and Markovitz, *Proc natn Acad Sci U S A*, **71**, 507–511, 1974)

Termination of transcription in bacterial DNA is not well defined, but sites in λ DNA have been mapped at which rho factor causes RNA polymerase to cease transcription *in vitro* As the λ map below shows, one site, (t_l), terminates leftward early transcription from p_l, another, (t_r), terminates rightward early transcription from p

Since only the early genes *N* and *tof* are expressed upon induction *in vivo* prior to synthesis of N protein, the same mechanism presumably prevails in the cell It is the synthesis of N protein which allows transcription to continue to the left past t_l and to the right past t_r

galK galT galE galO/P *exo cIII* t_l *N* p_l/o_l

p_r/o_r *tof* t_r *O P Q*

The accepted interpretation of these results has been to suppose that N protein acts at the sites t_l and t_r where transcription terminates But another interpretation is supported by the results of Adya *et al* Readthrough transcription of the galactose genes depends upon N protein since with an N^- prophage there is no escape synthesis of galactokinase—presumably transcription halts at the t_l site in the absence of N protein That the readthrough transcription supported by N has started at p_l is shown by the reduced readthrough synthesis of galactokinase found when a prophage bearing the *sex* mutation in p_l is induced The 12 min delay between prophage induction and galactokinase synthesis also is consistent with the idea that RNA polymerase must traverse the long distance between p_l and the *gal* genes, and the RNA made by readthrough is much larger than the usual 12–22S mRNA produced by fucose induction

Mutants in which foreign DNA has been inserted into the galactose operon constitute one of the few cases in which rho terminates transcription *in vitro*, De Crombugghe *et al* (*Nature new Biol*, **241**, 260–264, 1973) suggested that the polar effects of these mutations *in vivo* result from termination caused by rho and not by nonsense codons Polar mutations inactivate the gene in which they are located but also reduce the extent of expression of subsequent genes in the operon But when transcribed by N-dependent readthrough from the p_l promotor, the polarity of such an insertion in *galE* is suppressed, galactokinase can be synthesised Even more surprising is that the polarity of an entirely different type of insertion (not rho-sensitive) and a polar ochre nonsense mutation also are suppressed under readthrough conditions

The ability of polymerases that initiate transcription at p_l to pass subsequent rho-dependent termination sites thus contrasts with the inability to do so of polymerases that initiate at the galactose promotor The N protein responsible for anti-termination cannot, therefore, simply act at the termination sites at which its effect is exerted Rather does anti-termination depend upon where the polymerase initiates transcription Since phage 21 (which differs in the *N* gene from phage λ) canot complement λN^- mutants to allow readthrough, the site of action of N must be located in the region that is non-homologous between the phages This would be consistent with the idea that N acts at the p_l site, attaching to polymerase there, and turning it into what Adya *et al* describe as a "juggernaut" that ignores all rho-dependent signals for termination Thus only polymerases initiating at the site where N attaches to the enzyme can acquire the juggernaut capacity, all other polymerases terminate normally at rho-dependent sites The polymerase is seen as an enzyme to which other proteins may attach, in this case conferring anti-termination ability, perhaps in other cases changing the specificity of initiation

The effect on transcription of the initiation site is also seen by comparing the tryptophan operon located on the *E coli* chromosome with that translocated to a position to the left of gene *N* of phage λ when readthrough can occur Segawa and Imamoto (*J molec Biol*, **87**, No 4, 1974) show that nonsense mutations in the *trpE* (first) gene cause production of truncated messengers when transcription initiates at the tryptophan promotor, but long messengers continue to be synthesised when transcription instead takes place by readthrough from p_l Results showing that polarity of nonsense mutations is suppressed by readthrough transcription are cited from two other groups as in press

Poly (C) in viruses

Porter, Fellner and Carey (*Nature*, **248**, 675–678, 1974) recently showed that encephalomyocarditis (EMC) virus RNA contains a poly (C) tract which is about 100 nucleotides long and contains 80–90 C residues The authors argued that the poly (C) tract is probably not translated into protein but instead suggested that it may be involved in viral replication, possibly as a replicase binding site On page 342 of this issue of *Nature*, Brown, Newman, Stott, Porter, Frisby, Newton, Carey and Fellner report a similar analysis of several other picornaviruses, including some of economic and medical importance, in the hope that an understanding of the universality of poly (C) might give some clue as to its function In addition, they suggest that if poly (C) should prove to be virus specific then it may be possible to exploit the presence of this unusual structural feature in the design of specific antiviral reagents

Picornaviruses can be divided by physiochemical methods into five subgroups enteroviruses (for example polio, swine vesicular disease), cardioviruses (such as EMC, Maus Elberfeld (ME)), foot and mouth disease viruses (FMDV) and human and equine rhinoviruses Poly (C) tracts were detected in all the cardioviruses and FMD viruses examined but not in six different enteroviruses, three human rhinoviruses, nor in the togavirus Semliki Forest Virus The presence of poly (C) is therefore genus specific, and Brown *et al* point out that their oligonucleotide 'fingerprinting' data supports the subgrouping of picornaviruses mentioned above

The length of the poly (C) tract also varies, not only between viral subgroups but surprisingly between different strains and different subtypes of one serotype For example the cardioviruses EMC and ME have poly (C) tracts of 100 and 150 nucleotides respectively, and FMDV strains A61 and CGC, 150 and 200 nucleotides respectively

The location of the poly (C) within the viral RNA molecules is not yet certain but it is possible that the longest fragments originate from the 3′ terminus of the viral RNA If this proves to be the case then it is not surprising that the enteroviruses do not contain poly (C) since they contain the more familiar poly (A) tail in this position At present the function of poly (C), like that of poly (A), is unknown, it will be of interest to know whether similar structures are found in other, more exotic viral RNAs, or in host cell mRNA or HnRNA

Alan E Smith

(Zalkin, Yanofsky and Squires, *J biol Chem* , Franklin, *J molec Biol*)

The ability of a juggernaut polymerase to suppress polar nonsense mutants implies that all polar effects may be mediated at the level of transcription This resolves a conflict of some years standing as to how premature termination of protein synthesis may affect the availability of messenger for subsequent genes One view has been that dissociation of ribosomes within (but not at the end of) a gene makes the subsequent messenger regions susceptible to degradation, an alternative was to suppose that termination of transcription within a gene causes transcription to halt, although it has always been difficult to visualise molecular models for this relationship (see Lewin, *Nature new Biol*, **232**, 161–162, 1971) In view of the action of N as an anti-terminator, these new results support the idea that premature translational termination may provoke a rho-dependent transcriptional termination that can be antagonised by the anti-terminator action of N

Adhya *et al* propose that termination of translation in a gene allows rho-dependent termination of transcription to take place at the end of the gene by a normal polymerase, although a juggernaut polymerase may of course read straight through, suppressing the polarity of the mutation This implies that a rho-dependent termination site is present at the end of each gene in which polar mutations may occur but is rarely recognised in the usual course of events The termination signal at the end of an operon presumably differs from any internal signals and is recognised by all polymerases

Benjamin Lewin

Do pulsars make supernovae ?

from James Pringle

The brilliant explosion of a supernova heralds the demise of a highly-evolved, massive star When stars in the mass range 3–8 solar masses ($M_\odot$) have exhausted the hydrogen and helium in their central regions, they all evolve to red-giant configurations of very similar structure They have a dense core of about $1 M_\odot$, surrounded by a zone containing shells of burning helium and hydrogen, the whole of which is engulfed in a highly extended low-density envelope about a thousand times larger than the Sun

The details of what happens next are still uncertain It is known that some kind of explosion is triggered off, releasing in all about 10^{50} erg The outer layers of the star are blown off at speeds of some 8,000 km s^{-1}, gathering up the interstellar gas in their path and later becoming the wisps of gas which are known as 'supernova remnants' and of which the Crab Nebula is the most oft quoted example Eventually, the 'remnant' itself disperses to become part of the ambient interstellar medium which, in its turn, condenses to form stars It is precisely because a supernova explosion spews heavy elements from the heart of the dead star into the interstellar medium, that planets too can form and life as it is known can exist

Several specific mechanisms for triggering the initial explosion have been advanced—for example, the suggestions by Fowler and Hoyle that the core collapses caused by the photodisintegration of iron or that the explosive onset of carbon burning disintegrates the whole star Recent evolutionary calculations strongly indicate that collapse of the core in a highly evolved star, rather than its total disruption, is possible, at least for stars of 3–8 $M_\odot$ The collapsed core forms a 'neutron star'—a highly compact object with a typical density of 10^{16} g cm^{-3} This density is so great that the star's original magnetic field is compressed to a value around 10^{12} G and any rotation the core had before collapse is amplified until the newborn neutron star has a rotation period of a few milliseconds Thus a sizeable fraction of the gravitational energy released by the collapse of the core is converted into and stored as the rotational energy of the compact object The combination of rapid rotation and strong magnetic field causes most of the kinetic energy thus stored to be radiated away within a few thousand years, although the slow radiation of the residual rotational energy can be observed for much longer in the radio band as the regular bleeps from a pulsar These ideas are confirmed by the presence of two very short period, and presumably very young, pulsars in supernova remnants —the nebular remnants around the older pulsars would presumably have dissipated by now

Thus, the implosion of the stellar core is required, first, to release enough momentum to disperse the outer layers of the star at high velocity and, second, to release enough energy to account for the visual light curve Light curves have been caculated according to several different theories, but, in general, the first requirement is a problem if the energy is released on too short a timescale Two recent articles, one by Ostriker and Gunn (*Astrophys J Lett*, **164**, L95, 1971) and the other by Bodenheimer and Ostriker (*Astrophys J*, **191**, 465, 1974) suggest that the pulsar at the centre of the supernova can make a substantial contribution to the energy of the outburst Rather than having to release all the energy in one initial explosion, the authors argue that the power continuously radiated by the newborn pulsar is sufficient to assist in propelling the outer stellar layers up to high velocities They perform detailed calulations, assuming that the main energy source in a supernova is the dipole radiation from the central pulsar If it is intense enough, the radiation hollows out a cavity in the centre of the star and then expels the outer envelope at high speed As this shell of material moves outward, its density decreases rapidly and its transparency increases accordingly The peak of the light curve occurs when the timescale for the expansion of the envelope is approximately equal to the timescale on which photons can diffuse outwards through it The authors obtain good agreement with the observations of 'Type II' supernova light curves They comment on other effects—such as the possible presence of a dust shell around the pre-supernova star—which add complications and could improve agreement They predict that about 3–4 months after the light curve maximum ultraviolet and X radiation from the central cavity should become visible

Many a marmot

from our Animal Ecology Correspondent

All populations have a tendency to overproduce and, if they are not held in check, to damage the environment upon which they depend for existence Some ecologists believe that control is enforced only by the actions of extra-population forces, such as the climate Others hold that mechanisms which are dependent on the density of the population and which modify their effect according to the state of the population are at work In proposing this system of control, Nicholson stated that the only perfect density-dependent regulatory factor is intraspecific competition, all other factors play less direct, though strongly influential parts (*J Anim Ecol*, **2**, 132, 1933) Wynne-Edwards endorsed Nicholson's views and drew attention to the part played by social behaviour in the dispersion, and hence regulation, of animal populations (*Animal Dispersion in Relation to Social Behaviour*, Oliver and Boyd, Edinburgh, 1962) He stressed that intraspecific competition, be it for a territory, individual range, rank position in a hierarchy or the like, is never directed at the environmental resource in short supply but at a substitute The winner of a substitute goal gains exclusive rights to some primary environmental resource

If social behaviour really does play such an important part in the prevention of overpopulation (by allowing only a fixed number of goals to be open to competition) one might expect to observe changes where the environment embraces both harsh and kind habitats To investigate this the North American marmot offers as good a study animal as has yet ben found The species are morphologically very alike and occupy a huge range of habitats from the mountain tops above the tree line (Olympic marmot) through the upper forests to the valleys (yellow-bellied marmot) to the plains at sea level (woodchuck) A most interesting gradation in social behaviour has been reported by Barash which, if the interpretations are correct, shows clearly that the quality of social behaviour is correlated with the harshness of the environment (*Science*, **185**, 415, 1974)

Woodchucks living in fields and meadows at low elevation experience a growing season, when their food is rich and abundant, of about 150 days They are solitary and aggressive The male–female association last only as long as the brief courtship and mating themselves Females breed every year and their offspring disperse before the winter The yellow-bellied marmot lives at elevations where the growing season may last less than 100 days It is less solitary than the woodchuck but still maintains home areas They show a greeting behaviour—a pattern never seen in woodchucks—and greet their neighbours two or three times daily The Olympic marmot is restricted to the treeless alpine meadows of Olympic National Park, Washington, where the growing season may be as short as 40 days These are highly gregarious animals which live in well organised colonies of adults, 2-year-olds, yearlings and infants They do not protect home areas and wander about the colony without fear of attack Their level of aggression is low and in consequence greet one another about ten times as frequently as their yellow-bellied cousins Females breed every other year and youngsters do not disperse until they are 2 years old By the time they reach this age they weigh 70% of the adult weight In comparison woodchucks (weighing 80% of adult weight) disperse before their first winter

The important thing for a species is to leave the maximum number of surviving offspring that the habitat will carry Because of the varying durations of growing seasons encountered by marmots the optimum age for dispersal varies between a few months and 2 years Barash demonstrates that the environment dictates when dispersal takes place through the effect of growth rate on aggressiveness If over-winter mortality has been high and the population needs replenishing, the level of aggression is a little lower and a higher proportion of the dispersers remain, and *vice versa*—a very clear example of adaptive social behaviour

Several factors may complicate Barash's simple interpretation—for example, female Olympic marmots breed once in 2 years while the other species bred annually The reproductive physiology and feeding ecology of a species play a fundamental part in moulding the shape of the behavioural fine tuning Barash's work demonstrates beautifully that the barrier between ethology and ecology is more imagined than real

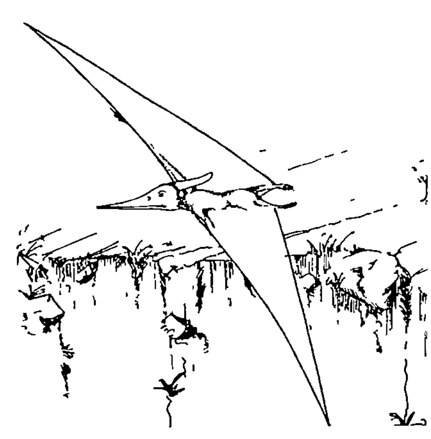
Prehistoric gliders

from a Correspondent

IN a study of the biomechanics of *Pteranodon*, Bramwell and Whitfield discuss the structure and aerodynamics of the largest flying animal to have existed As *Pteranodon* represented the end product of pterosaur evolution it was likely to show a high degree of structural and aerodynamic refinement and this has been largely confirmed *within this study* (*Phil Trans R Soc*, **B267**, 503–592, 1974)

Any such study as this is based upon conjecture—indeed herein lies one of its fascinations—but the authors have minimised uncertainty in this respect by utilising an interdisciplinary approach, combining both engineering and palaeontology to formulate conclusions The application of engineering to an extinct animal is obviously extremely difficult, particularly as parts of the fossil animal were missing The authors have, however, used the best data available and where their conclusions are open to doubt this in no way infers a criticism of this study, but of the lack of information particularly within the field of low speed aerodynamics

From available fossil and estimated sizes the strength of the bones in the wing spars has been calculated The general factor of safety is approximately 5 which is a reasonable value for a flying animal with the assumed flight activities of *Pteranodon* The most surprising feature of the structure is a factor of safety of only 2 for the humerus It is possible that the assumed strength values for this bone were incorrect and the authors have considered this as one possibility by suggesting that a stronger, more brittle bone material was practical They also put forward a more feasible explanation in that part of the loads could be taken by some of the flight muscles being inserted well out along the humerus



Bramwell and Whitfield's interpretation of how *Pteranodon* soared in the hill lift caused by a cliff

From tests in a wind tunnel Bramwell and Whitfield provide a new explanation of the large crest on the animal's head This structure had previously been thought to have the effect of a rudder or steering device but these authors clearly show that it was a weight-saving device, by balancing the aerodynamic loads on the beak it could reduce the required neck muscles and thereby save weight

The aerodynamic characteristics of the wing were based on the use of data for the Gottingen 417a curved plate as being the nearest to the *Pteranodon* wing section There is a discrepancy between the drag values of the Gottingen 417a aerofoil section as presented by Schmitz and that presented in Figure 44 by Bramwell and Whitfield, but it is obvious that these authors have used the data from Schmitz for all their performance estimations

It is unfortunate that there are no more recent data than those for the 417a section nor any more appropriate aerofoil section on which to base the estimations of *Pteranodon*'s performance From a polar curve of *Pteranodon* the best flying speed was about $8\ \mathrm{m\ s^{-1}}$ with a minimum sinking speed of $0\ 43\ \mathrm{m\ s^{-1}}$ The highest useful flying speed was about $14\ \mathrm{m\ s^{-1}}$ These estimates of performance are realistic as any small discrepancies in the assumed wing drag characteristics are unlikely to have a profound effect on the overall lift/drag ratio

A comparison between the performances of *Pteranodon*, an albatross and a modern high performance glider shows that *Pteranodon* was a very efficient glider with a sinking speed of about half that of the other two From estimates of power required it seems that *Pteranodon* was also just capable of powered flight for short durations

Bramwell and Whitfield conclude that *Pteranodon* was primarily a glider that utilised sea thermals for lift while searching for food Although dynamic soaring is used by the albatross to sustain flight over the sea, the authors show that *Pteranodon* was unlikely to utilise this form of lift because of its low flying speed and the critical conditions for the required wind gradient

Heat flow in a metamorphic crust

from Peter J Smith

IN investigations which attempt to relate the Earth's heat flow to crustal structure and composition, it has been usual to view the crust in terms of homogeneous igneous rocks Thus, for example, when Roy *et al* (*Earth planet Sci Lett*, **5**, 1, 1968) demonstrated the correlation between geothermal flux and surface heat production, they made it clear that their measurements and analysis applied specifically to intrusive granitic bodies But as Smithson and Decker (*Earth planet Sci Lett*, **22**, 215, 1974) point out, although crustal models involving homogeneous igneous rocks have the merit of simplicity they may be a poor general representation of the real Earth Fifty years ago, Clarke and Washington (*Prof Pap US geol Surv*, **127**; 1924) could plausibly argue that 95% of crustal rocks are igneous, but modern work is more likely to stress the importance, and even the predominance, of metamorphic rocks with characteristic heterogeneities

Evidence for the modern view is extensive The Wind River Mountains of Wyoming, for example, are a broad anticlinal uplift with a core of Precambrian rocks largely comprising migmatite Borehole data suggest that in places such rock is at least 4 km thick, in addition to which denser metasedimentary rocks such as mica schists, garnet schists and metagraywacke may be found at structurally higher levels Again, a profile through the Ivrea zone of the Alps has been interpreted in terms of an upper crust comprising metamorphic rocks such as mica schist, a middle crust which is granitic in the form of migmatite and granitic gneiss, and a lower crust consisting of dehydrated mafic metamorphic rocks and diorites Migmatites underlying other metamorphic rock types are also found in Canada, east Greenland, southern Norway and central Europe Indeed, Barth and Reitan (in *The Precambrian*, Interscience, 1963) have estimated that as much as 93% of the exposed southern Norwegian Precambrian may be metamorphic—a figure which corresponds well with Wilson's picture (in the same volume) of the Canadian Shield as a region of metamorphic rocks "in which areas of granite and other igneous rocks are interspersed"

But where does all this (and much more) leave the analysis of terrestrial heat flow in terms of simple igneous and homogeneous structures? The answer is, of course, a rather poor approximation to the truth, but an approximation which can nevertheless be built on to give a picture closer to reality Smithson and Decker build by proposing the following three-zone model of stable continental crust

- The upper zone consists largely of metamorphic rocks of intermediate composition with a mean density in the range 2 75–2 80 g cm^{-3} and seismic P wave velocities ranging from 6 2 to 6 5 km s^{-1} Geological relationships and gravity interpretations suggest that this surface zone could be 5–12 km thick, although Smithson and Decker use a thickness of 8 km The metamorphic rocks actually comprise mica schists, metagraywackes (biotite gneiss and quartzo-feldspathic gneiss), greenstones and amphibolites According to Shaw (*Geochim cosmochim Acta*, **31**, 1111, 1961), the mean heat production within the Canadian Shield is 4 heat generation units (h g u), and it is known that intrusive granites generally have a higher heat production The intervening metamorphic rocks of the upper zone must therefore have a heat production lower than 4 h g u The estimate made by Smithson and Decker is 3 h g u, based on a mixture of mica schists, metagraywacke and mafic rocks
- The middle zone is also 8 km thick and comprises rocks which are less dense and more granitic than those of the zone above This is the migmatite zone and consists largely of granitic gneiss and augen gneiss intermixed and interlayed with biotite-rich gneiss and amphibolite lenses The mean density of this very heterogeneous region is about 2 72 g cm^{-3}, P wave velocities lie in the range 6 0–6 3 km s^{-1} and the highly variable heat production has a probable average of about 5 h g u
- The lower zone, 18 km thick, is composed of dense rocks (2 80–3 00 g cm^{-3}) with high seismic velocities (6 5–7 0 km s^{-1}) Both field and laboratory studies show that at likely pressures and temperatures in the lower crust mafic rocks would be recrystallised as metamorphic rocks in the amphibolite, granulite or eclogite facies, although the last of these is unlikely Smithson and Decker argue that granulite facies rocks actually comprise the bulk of the lower crust, although they expect pockets of amphibolite to coexist with them Heat production is estimated to be 0 5–5 h g u

Having proposed this more "realistic" model, however, Smithson and Decker are at pains to emphasise that the zones should not be interpreted as discrete layers The zones are heterogeneous and grade into each other irregularly, so that even the quoted thicknesses cannot be regarded as universal Average values tend to conceal considerable diversity in both the horizontal and vertical directions Thus the model is a generalisation which may apply in the specific form given only in relatively few localities

Notwithstanding these restrictions, if the surface heat flow for stable continental areas is taken to be 1 2 heat flow units (h f u) in accordance with the suggestion from Blackwell (in *The Structure and Physical Properties of the Earth's Crust*, American Geophysical Union, 1971), the model predicts a heat flow contribution of 0 3–0 5 h f u from the upper mantle The upper limit of this range then leads to temperatures of 130° C at a depth of 8 km, 407° C for the Moho at 34 km, and 538° C at 54 km in the upper mantle—temperatures which are comparable with, but slightly lower than, those obtained by Blackwell from other models The controversial point to arise here is the claim by Smithson and Decker that such low temperatures rule out the possibility of a universal seismic low-velocity zone produced in the crust by thermal effects A low-velocity zone may arise in places in the upper or middle crust because of variations in composition, but it would be unlikely to exist over an area of even continental extent

In search of a meaning

from a Correspondent

THE first plenary meeting of the International Society for Research on Aggression, whose objects are as much educational as scientific, was held in Toronto on August 17 and 18 The constitution of the society refers to "the destructive and constructive aspects of aggression", but does not define aggression and in fact definition was the most prominent theme of the meeting, which was attended by fifty or so researchers (about one-fifth of the total membership) from fields as various as anthropology, psychiatry, and experimental psychology

On the question of definition, K Lagerspetz (Swedish University, Turku) pointed out that although most definitions include the delivery of noxious stimulation to another organism, this does not always apply in psychiatry or the social sciences She asked whether, nonetheless, unifying concepts exist for all the fields of behaviour to which the term 'aggressive' is applied In her view the notion of an 'aggressive drive' is not useful, and is critical of the frustration hypothesis and analyses in terms of learning and inhibitions

Adopting an historical perspective, J P Scott (Bowling Green State University, Ohio) suggested 'disaggregation', or disruption of normal social patterns, as a general concomitant of anti-social violence in both human and animal societies

The pluralism advocated by Lagerspetz was echoed in a discussion on classification and definition K E Moyer (Carnegie-Mellon University, Pittsburgh), S Rosenzweig (Washington University, St Louis) and P A Corning (Stanford University) all emphasised the heterogeneity of the phenomena with which members of the society are concerned The complexities of human behaviour in this regard were exemplified in a remark by J Paddock (University of the Americas, Oaxaca), during an absorbing communication on anti-violent and 'normal' communities in which he remarked that non-violent and anti-violent attitudes can be militant

Education as a possible unifying activity for the society was proposed, and briefly discussed Authentic information on anti-social violence in human communities and on the social and intolerant behaviour of animals, is much needed, notably by teachers in schools and universities, at present they have to contend with a flood of misinformation and entertaining but unscientific writing The refreshing rigor of the papers and discussions at this meeting suggest that the society could do much to remedy this situation

Lamb shifts from intensity measurements

from B P Kibble

PHYSICISTS at the University of Windsor, Canada have found an interesting new way to measure the small energy change known as a Lamb shift which is the effect of radiation reacting on the atom emitting it In their report Wijngaarden, Drake and Farago (*Phys Rev Lett*, **33**, 4, 1974), following the theoretical treatment of Drake and Grimley (*Phys Rev*, **A8**, 157, 1973), describe an indirect measurement in terms of an intensity ratio of the Lamb shift in the lowest excited states of hydrogen

Two of the states concerned, denoted as $2P_{1/2}$ and $2P_{3/2}$, have angular momentum associated with them which differs from that associated with the ground state An atom in either of these states can revert to the ground state by emitting photons of slightly different energies as, because of relativistic corrections, these states have energies differing by a small amount ΔE A third state denoted as $2S_{1/2}$ also differs in shift $\mathscr{S}$ approximately equal to 0 1 energy from the $2P_{1/2}$ state by a Lamb ΔE, but has associated angular momentum which is the same as that of the ground state so that an atom in it does not radiate a photon In previous measurements transitions between this S state and the P states resulting in photon emission could be induced by a radiofrequency field whose frequency matches, and is a measure of, the energy differences $\mathscr{S}$ and $\Delta E-\mathscr{S}$

The alternative approach of the Canadian workers is to note that when the 'pure' states are mixed by the presence of an electric field, the total photon emission is no longer equal in all directions, but is greater in the direction of the electric field than in the perpendicular direction The ratio is related to $\mathscr{S}/\Delta E$ and since ΔE is already known very precisely from radiofrequency spectroscopy, $\mathscr{S}$ can be deduced

Measuring radiative intensities, even when only the ratio is required, does not seem likely to be very accurate but there are particularly favourable features in this case The photons are energetic enough for a high proportion of them to eject countable single electrons from a detector surface and, when increased by an electron multiplier, the resulting pulses of electrons can be accurately counted If the difficulties of variation of this proportion and of the discriminator level which differentiates between large signal pulses and small noise pulses can be overcome, the direction of the electric field can be controlled sufficiently precisely, the results can be extrapolated to a condition of zero electric field strength and corrected for the occasional coincidence of pulses, then an accuracy comparable to that obtained by radiofrequency methods may be attained So far Wijngaarden and his colleagues report an accuracy of about 1%, which is two orders of magnitude less than that obtained by radiofrequency methods, but the prospects for improvement are encouraging The method may well be suitable for Lamb shifts in heavier hydrogen-like ions where a method based on the total photon emission from the S state by application of an electric field has hitherto been used

Early mammalian development

from Michael Balls and Arthur Wild

RECENT dramatic technical developments have enabled the mammalian embryo, which normally remains hidden within the female reproductive tract, to be viewed and manipulated These advances were reflected in the programme of the twenty-seventh meeting of the British Society for Developmental Biology, on the early development of mammals, held at the University of East Anglia on September 9–12 In a group of papers on *in vitro* techniques, Dr D Whittingham (University of Cambridge) dealt with problems related to the fertilisation, culture and storage of mammalian ova, and Dr M Kaufman (Weizman Institute, Revohot) reviewed recent developments in experimental parthenogenesis and considered possible reasons for the death of parthenogenetic mouse embryos in early post-implantation stages Dr A McLaren (University of Edinburgh) discussed the culture of embryos over the period when implantation would normally be occurring *in vivo*, and the culture of post-implantation rat embryos was described by Dr C Steele (University of Cambridge)

Contrary to Dalcq's rigid predetermination idea, experiments reviewed and described in papers by Dr I Wilson (University College of North Wales, Bangor) and Dr S Kelly (University of Oxford) clearly demonstrated the totipotency of the blastomeres up to and including the eight-cell stage, pointing to a labile, epigenetic control of the differentiation of two distinct cell populations (trophoblast and inner cell mass) The further development of these two cell types was considered by Dr R Gardner (University of Oxford), using chimaeras, and by Dr J Ansell (University of Cambridge) and Dr M Sherman (Roche Institute, Nutley, New Jersey), using *in vitro* trophoblast outgrowths

Abnormalities of development can often be used to throw light on mechanisms operating in normal development, mutations in the complex T locus of the mouse are being studied to this end Dr N Hillman (Temple University, Philadelphia) proposed that metabolic errors elicited by mutant *t* alleles are involved in embryonic lethality, whereas Professor D Bennett (Cornell University, New York) suggested that the T locus controls a specific cell surface antigen which is of great significance in development

The expression of paternal antigens, especially those of the H-2 locus, could have important immunological consequences in development One theory as to why the mother does not normally reject the foetus as an allograft is that paternal antigens are not expressed on trophoblast cells, and Dr D Billington (University of Bristol) discussed the evidence for this hypothesis Antigen expression was also the subject of a paper by Professor F Jacob (Institut Pasteur, Paris), but he described experiments on teratocarcinoma cells, which also have great potential for studies on the basis of normal developmental mechanisms Dr D. Solter (Wistar Institute, Philadelphia) described methods for producing benign teratomas and re-transplantable teratocarcinomas, and the possible immunological factors regulating them Dr M Evans (University College, London) dealt with the characteristics of established cell lines derived from teratocarcinomas

Much is now known about the synthesis of various macromolecules and the fine structural changes that occur in the pre-implantation embryo The genetic activity underlying these events as expressed in the nuclear and mitochondrial genome was considered by Dr L Pikó (Pasadena, California) Dr C Ford (University of Oxford) discussed the effects of genetic imbalance, and a model system for studying its consequences in certain strains of mice, Dr B Cattanach (Harwell) described sex reversal in mammals and the use of *Sxr* mice in attempts to understand this intriguing problem

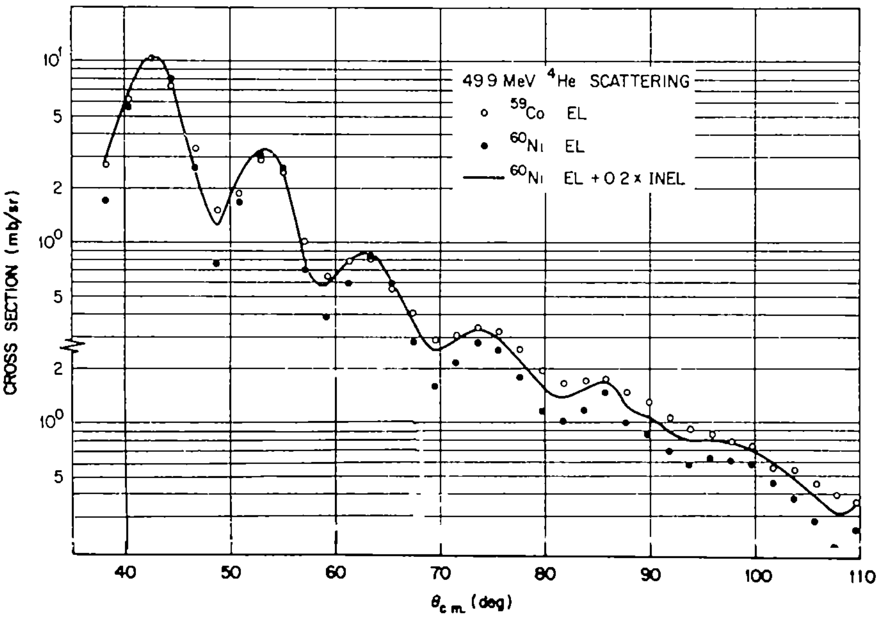
The next group of papers concerned the significance of cell interactions in the morphogenesis of organs, such as the kidney (Dr L Saxén, University of Helsinki), in pre-natal erythropoiesis (Dr R Cole, University of Sussex), and in pre-natal lymphopoiesis (Dr M Ritter, University of Oxford) Dr E Pantelouris (University of Strathclyde) put forward the hypothesis that the thymus, as evidenced by the effects of genetic athymia, might have an endocrine function in female reproductive physiology, and, finally, Dr J McKenzie (University of Aberdeen) presented evidence that early cell death might be the underlying cause of human morphological abnormalities hitherto ascribed to so-called 'amniotic bands' The proceedings of the symposium will be published in the spring or early summer of 1975

Target-spin effects in elastic scattering

from P E Hodgson

MEASUREMENTS of the elastic scattering of helions and alpha particles by nuclei have shown that the differential cross sections for odd nuclei oscillate less strongly with angle than the corresponding cross sections for neighbouring even nuclei Since even nuclei have spin zero and odd nuclei have spins greater than zero it was at first suggested that this difference may be explained by a coupling between the relative orbital angular momentum **L** and the target spin **I** which can be represented by a **L.I** term in the optical potential This term is similar to the **L**σ spin-orbit term which is known to reduce the oscillations of differential cross sections But this explanation of the difference was rendered unlikely by Satchler's calculations (*Nucl Phys*, **45**, 197, 1963) of the magnitude of the **L.I** target-spin term, which showed that it is far too weak to account for the observed differences in the cross sections

It has recently been suggested by Satchler and Fulmer (*Phys Lett*, **50B**, 309, 1974) that another possible explanation may be found in the different shapes of neighbouring odd and even nuclei due to particle–core coupling According to this model the odd nucleus is considered as a single particle (or hole) coupled to states of the core with spin **L**, where the core is the adjacent even nucleus The coupling allows the valence particle to polarise the core and thus gives it a quadrupole moment, and the extra scattering from the quadrupole moment has the effect of smoothing the angular distribution of the scattering from odd nuclei



Differential cross sections for the elastic scattering of 49 9 MeV α particles by ^{59}Co and by ^{60}Ni showing the difference in the oscillatory structure The full line is the cross section for ^{59}Co calculated as described in the text from the cross section for ^{60}Ni plus auxiliary data, and agrees well with the ^{59}Co measurements

To test this explanation, Satchler and Fulmer measured the differential cross section for the elastic scattering of 49 9 MeV α particles by ^{59}Co ($I=7/2$) and by ^{60}Ni ($I=0$) As shown in the figure, the ^{60}Ni cross section oscillates significantly more than the ^{59}Co cross section

The theory of elastic scattering from odd and even nuclei taking into account the quadrupole moment scattering predicts that they are related by

$$\sigma_{\mathrm{EL}}(\mathrm{odd}) \approx \sigma_{\mathrm{EL}}(\mathrm{even}) + \sum_{L} K_L \sigma_{\mathrm{INEL}}\ (\mathrm{even},\ 0^+ \rightarrow L^+),$$

where K_l is a coefficient that can be found from the measured 2^L-pole moments of the ground state of the odd nucleus and the measured strength of the electromagnetic excitation of the corresponding state in the even nucleus The inelastic cross section σ_{INEL}(even, $0^+ \rightarrow L^+$) for the excitation of an L^+ state in the even nucleus is also known experimentally It is thus possible to calculate the elastic scattering from an odd nucleus from measurable properties of the neighbouring even nucleus in a direct way using a simple model

The ^{59}Co cross section was found in this way from the ^{60}Ni cross section and the appropriate inelastic scattering and electromagnetic transition data, and the results are shown by the full line in the figure This agrees very well with the measured results for ^{59}Co, indicating that quadrupole moment scattering is indeed responsible for at least the major part of the difference between the scattering from ^{59}Co and ^{60}Ni

Further calculations showed that the same model is also able to account for the observed differences between the elastic scattering of 60 MeV helions by ^{59}Co and ^{60}Ni It is likely that it could account for other odd–even differences that have been observed in elastic scattering, except for nuclei with $I=\frac{1}{2}$, for which quadrupole moment scattering is zero Examples of this occur for ^{89}Y and ^{207}Pb, and such nuclei are therefore suitable for the study of target-spin effects

This work sheds further light on the character of the optical potential It would presumably be possible to fit the observed difference between the elastic scattering from odd and even nuclei by including an **L.I** term in the potential and arbitrarily adjusting its strength This strength would, however, vary from nucleus to nucleus depending on the deformation and would be much greater than the value calculated from the microscopic theory of the optical potential This is clearly unsatisfactory, and a much better way of analysing the data is provided by the present work, which shows that a more detailed account of the physics of the interaction enables the data to be understood in a systematic way without arbitrary parameters

Ins and outs of cell membranes

from a Correspondent

THE chemical assymmetry of biological membranes in the distribution of lipids, proteins and carbohydrates at each face of the lipid bilayer was no doubt implicit in the early membrane models Recently this proposal has been made explicit, largely through the introduction of a variety of reagents that react to form stable derivatives of membrane components without penetrating the lipid bilayer The usual experiment is to react in this way intact cells, in which case only components accessible at the outer surface are labelled, or lysed cells when additional sites located at the cytoplasmic side of the surface membrane also become available for reaction

In a recent issue of the *Journal of Molecular Biology* (**87**, 541–562, 1974) Whiteley and Berg describe two new homologous imidoesters that react under physiological conditions in respectively a non-penetrating or a completely penetrating manner These reagents can be tagged with ^{3}H or ^{14}C so it is possible to doubly label the membrane in such a way that reactive sites situated at the inner or outer face or both faces of the membrane can be identified Components that span the membrane can be distinguished from those having copies occupying sites on both sides of the membrane by the sensitivity of the former to proteolysis of intact cells which reduces the size of components accessible on the outer surface

The non-penetrating reagent described by Whiteley and Berg, (IAI) isethionyl acetimidate ($CH_3CNH\ OCH_2CH_2SO_3^-$), is polar and lipid insoluble, the penetrating reagent (EAI), ethyl acetimidate ($CH_3CNH\ OCH_2CH_3$) is relatively non-polar and lipid soluble The product of the reaction of these reagents with amino groups is, however, the same amidine Reaction of intact human erythrocytes or lysed erythrocyte ghosts with EAI labels haemoglobin to the same extent, whereas the haemoglobin of intact cells is only 0 6% as reactive to IAI as free haemoglobin Therefore, EAI penetrates the membrane and reacts with cytoplasmic proteins at about the same rate as occurs extracellularly in buffer at *p*H 8 The membrane amino groups reacting with these reagents are in proteins or lipids

When intact cells are labelled with IAI only a fraction (about 2×10^6 sites per cell) of the amino groups substituted by reaction of the reagent with lysed cells are labelled and 90% of the counts are in protein There are nearly 20 times as many reactive protein amino groups and nearly 100 times as many lipid amino groups (phosphatidyl serine and phosphatidyl ethanolamine) on the inner membrane surface as on the outer surface of the erythrocyte These findings are in general agreement with assignments made by other labelling methods

The use of these new imidoesters however makes an important contribution to recent discussion of the validity of surface labelling techniques Much of the earlier work has used low concentrations of reagents, and since the labelling often does not proceed to saturation, sites on the inner membrane surface of intact cells may be weakly labelled even by totally penetrating reagents because the large excess of cytoplasmic protein, for example haemoglobin, mops up any reagent appearing at the cytoplasmic face of the surface membrane Therefore, it is not always completely clear whether the non-reactivity of cytoplasmic face membrane components to a particular reagent means that the reagent is incapable of penetrating the lipid bilayer This argument has been considered to explain the preferential labelling of outer face components by low concentrations of reagents that were supposed to be completely penetrating Whiteley and Berg show, however, that the labelling of free membrane amino groups by EAI is the same in intact cells or lysed cells Labelling of spectrin polypeptides, for example, proceeds to the same extent by exposure of intact cells to EAI or lysed cells (but not intact cells) to IAI ($3\ 0\times10^7$ and $1\ 2\times10^7$ amidines per cell respectively) Clearly then, these proteins (which include spectrin and a number of smaller proteins) exist exclusively on the inner surface face and are fully reactive to a completely penetrating reagent added at saturating concentrations Whiteley and Berg also show convincingly that membrane reorganisation caused by lysis must be slight since intact cells treated with EAI do not incorporate more EAI into membrane components on further reaction with fresh reagent added to lysed cells It does not, of course, prove that limited reorganisation might not occur during hypotonic lysis, for example, to make certain surface groups more reactive with the non-penetrating imidoester IAI This can only be decided by mapping the positions of amidine residues along membrane polypeptides labelled under the different conditions

As an alternative to small chemical reagents, surface labelling with enzymes (lactoperoxidase or galactose oxidase) is extensively used The reaction of membrane components with galactose oxidase is usually followed by labelling of the aldehyde group generated at C6 of galactose residues by the enzyme with ^{3}H-NaBH$_4$ In a new development with wide practical potential, particularly for the electron microscopic visualisation of membrane glycoproteins, Heitzmann and Richards (*Proc natn Acad Sci, U S A*, in the press) react the aldehyde groups with biotin hydrazide to form hydrozones The bound biotin is in turn located by ferritin-linked avidin The association constant of the biotin–avidin interaction is about 10^{15} M^{-1}, that is several orders of magnitude larger than the interaction with a ferritin–lectin, another favourite reagent for localisation of membrane carbohydrate groups Staining of membranes containing fixed biotin is therefore extremely rapid, minimising non-specific background If required the galactose oxidase treatment can be dispensed with and a suitable derivative biotinyl-N-hydroxysuccinimide ester is reacted directly with protein amino groups

The range of enzyme reagents has been extended by the introduction of enzymatic phosphorylation of proteins for the labelling of surface proteins (Kinzel and Mueller, *Biochim biophys Acta*, **322**, 337–351, 1973) Protein kinases are ubiquitous enzymes transferring the terminal phosphate of γ-^{32}P-ATP to serine or threonine residues of protein, and usually show a fairly broad substrate specificity Kinzel and Mueller find that phosphorylation of intact HeLa cells by exogeneously added protein kinase from rat skeletal muscle labels about 15 polypeptide subunits separable by SDS-polyacrylamide gel electrophoresis A heavily labelled component has an apparent molecular weight of about 55,000 One possible complication using this procedure is the presence of endogenous protein kinases in some cell membranes The intrinsic phosphorylation of proteins by these kinases probably accounts for the slow appearances of hydroxylamine stable phosphates when cells or isolated plasma membranes are incubated alone with γ-^{32}P-ATP Phosphoproteins containing aryl phosphate bonds formed during the process of ATP hydrolysis catalysed by surface located ATPases are likely to be less of a problem, particularly if the reaction conditions are arranged so that any inorganic phosphate released from γ-^{32}P-ATP by a surface enzyme is trapped in an external medium containing a high concentration of cold phosphate

Indian astronomy in the era of Copernicus

Krishnan D. Mathur

Department of History and Philosophy, Federal City College, Washington DC 20001

An observatory, in use in India during the time of Copernicus, was part of an astronomical tradition dating back to the second millenium BC

In the wake of the quincentenary celebrations for the great Polish astronomer-philosopher Nicolaus Copernicus, it seems appropriate to recall that during his lifetime Indian astronomical methods were being used in Newminster, England as well as in other parts of Europe[1] At about that time there was also a functional observatory, called *Man Mandir*, in Benares, India, the fame of which attracted European scholars until the nineteenth century

Scholars and traders went to India from Europe in search of knowledge as well as merchandise much earlier than the sixteenth century, and more steadily after the voyage of Vasco da Gama to Calicut in 1498 During the eighteenth century wealthy patrons and learned societies, such as the Royal Society of London and the Royal Society of Paris, sent scholars to bring back accounts of what they saw

Among the British scholars visiting the Benares observatory was the distinguished Sir Robert Barker (1729-89) a member of parliament, who gave an eye-witness account

> "I saw a number of instruments yet remaining, in the greatest preservation, stupendously large, immoveable from the spot, and built of stone, some of them being upwards of twenty feet in height and although they are said to have been erected two hundred years ago, the graduations and divisions on the several arcs appeared as well cut and as accurately divided, as if they had been the performance of a modern artist The execution in the construction of these instruments exhibited a mathematical exactness in the fixing, bearing and fitting of the several parts in the necessary and sufficient supports to the very large stones that composed them, and in the joining and fastening each into the other means of lead and iron "[2]

Dr Reuben Burrow (1749-92), assistant to Professor Maskelyne the Astronomer Royal at Greenwich, was given the respectable position of Chief Engineer of the East India Company in 1782 In an article entitled, "Hints concerning the observatory of Benares", which is preserved in the British Museum Papers of the Right Honourable Warren Hastings, the first Governor-General of Bengal, from 1774-85 (reprinted in ref 3) Burrow observed

> "In all the Grecian, Roman and Egyptian remains there does not appear to be the least vestige of an observatory but fortunately for astronomy there is a large quadrant existing at Benares which from the intent of its construction must necessarily have been placed in the plane of the meridian when the observatory was erected, and as this quadrant is an immovable structure of solid massy stones, and consequently not liable to vary its azimuth, or bend like European quadrants, the transits and altitudes of a number of stars may be taken with it, by a proper contrivance, and its position with respect to the meridian and equator and c, found out with the greatest exactness, from whence many useful conclusions may be drawn "[3]

As late as 1823, the writers of the *Encyclopaedia Britannica* considered *Man Mandir* to be one of the five most celebrated observatories of the world, the other four being the Greenwich observatory built by order of Charles II in 1676, the Paris observatory built by order of Louis XIV in 1667, Tycho Brahe's observatory in the Island of Hven, construction of which began in 1576, and the Peking observatory rebuilt by order of the Ch'ien Lung, the Emperor of China in 1744 (ref 4)

First-hand information available to the Royal Society of London from scholars and experts sent to India led the *Encylopaedia Britannica* to state

> "The science for which the bramins, however, were most remarkable, is that of astronomy, and in this their progress was so great, as even yet to furnish matter of admiration to the moderns "[5]

The interest in astronomical sciences in India, which goes back to the Vedic period, about 1500 BC, was probably cultivated and developed in connection with the religious need for consecrating ceremonies and sacrifices at specific times and seasons The Vedic rites of Agni-cayana (fire altars) required the construction of shrines of strictly accurate geometrical dimensions where sacred ceremonies were to be performed at a specific and exact time and date[6]

Since the determination of the units of time is contingent upon the accuracy with which the celestial phenomenon can be observed, the needs to study problems of mathematics and astronomy arose simultaneously This resulted in the determination of solstices and equinoxes, division of the Sun's yearly path into 360 divisions and of the zodiac into twelve equal parts, the discovery of the planets and so on The pole star was located as the pivot around which the celestial sphere rotated The Sun was considered the central point, the director of the Earth, around which all the planets revolved "May the resplendent sun that comes from the centre of the expanse of water of the vast ocean, purify me ", and "The sun generates all the earthly directions one by one and controls the seasons Only the sun is the Lord of our universe "[7]

The growth of astronomical sciences continued with the compilation of the first systematised text of astronomy, *Vedanga Jyotisha*, by Lagadha in about 600 BC (dates vary) This text deals with planetary motions, describes eclipses and divides the ecliptic into 27 or 28 equal parts, called nakshatras The nakshatras determined the Moon's position in relation to stars each day, the Moon completing its sky journey in 27 or 28 days[8,9]

The acquisition of some of this knowledge during the Vedic period might have been a result of interaction with the Mesopotamian culture, just as there is evidence of the interaction of Greek and Indian Sciences since the early Christian era It is well known that Greek scholars visited India from time to time, and some of them settled there, contributing towards the development of what may be termed the Indo-Greek Sciences[10] The concept of Earth being the centre of the Universe was the contribution of the Greeks to the Indian thought

The *Paulisa Siddhanta*, one of the five treatises on astronomy compiled in Sanskrit by Varaha Mihira in the fifth century AD uses Greek methods of computation, for example, in the *Table of Sines*, the subdivision of the radius is into 120 instead of 60 parts as prevalent in India This work also mentions the longitude of Alexandria on one hand and of Ujjain and Benares on the other, thus attesting to the significance of Benares (as well as Ujjain) as the centres of astronomical sciences in ancient India[9]

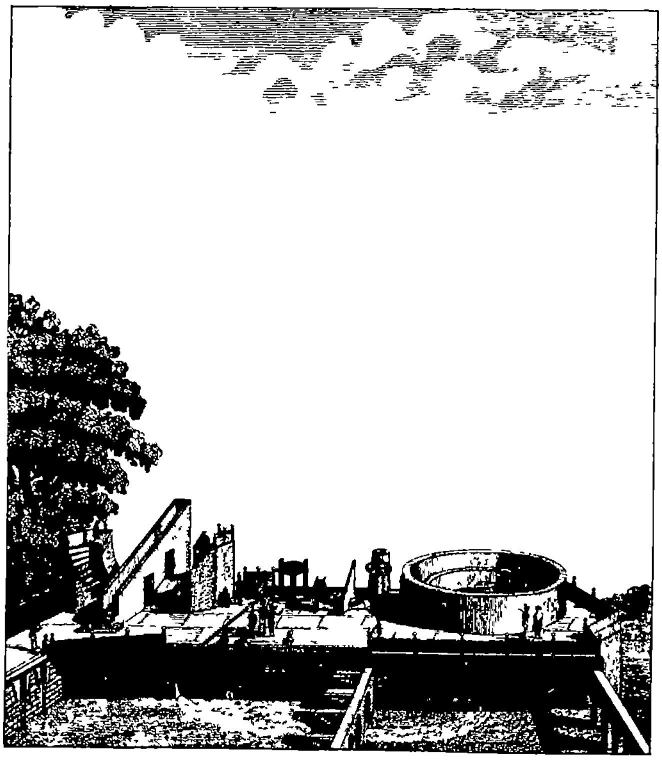

Fig 1 The observatory at Benares, from the *Encyclopaedia Britannica* of 1778 The drawing is by Sir Robert Campbell, chief engineer of the East India Company

By the seventh century, the Indian astronomers had discussed astronomical constants and sine tables, explained motions of the Sun, the Moon, and the planets, charted eclipses, and explained the theory of rotation of the Earth Alberuni, the Persian scholar, who visited India in the eleventh century AD paid a tribute to a seventh century Indian astronomer "Brahmagupta holds a remarkable place in the history of Eastern civilisation It was he who taught the Arabs astronomy before they became acquainted with Ptolemy, for the famous Sindhind of Arabian literature frequently mentioned but not yet brought to light, is a translation of his Brahmasiddhanta "[11] Indian astronomy was introduced in the Middle East after the time of Caliph Al-Mansur (eighth century AD) and subsequently reached Europe Until the twelfth century AD, the two well known centres of astronomical research were Ujjain and Benares Ujjain had the same reputation in ancient India as Greenwich has in the modern world There is, however, no record of astronomical instruments at Ujjain earlier than those installed by Jai Singh in 1734, and even these have disappeared today

Ancient records were lost because the astronomical sciences, along with the others, were dealt a severe blow after the invasions of Shihabuddin Muhammad Ghouri and his General Qutubuddin Aibak in the latter part of the twelfth century AD In 1194 Benares was ransacked and almost every monument of ancient Indian civilisation was irretrievably damaged The annihilation was so complete that no records of ancient learning were spared from destruction In 1199 Vihara (Bihar), a centre of learning and famous as the site of a college, was laid in ruins The great university of Nalanda was destroyed, its spacious library burnt to ashes, and practically all Buddhist literature and monks exterminated The religious fanaticism that continued in the thirteenth and the fourteenth centuries resulted in the collapse of astronomical activity during this period, the last celebrated Indian astronomer being Bhaskara II, 1150 AD This historical background is essential to an evaluation of the contradictory information now available about the Benares observatory

Astronomical activity was revived at the beginning of the Copernican era Works of mathematical astronomy and astronomical calculations, though limited to computation of data and tables and commentary of previous works, were compiled by Gangadhara (1420), Ganakananda (1447) and Makaranda (1478), followed by further works in the sixteenth century by Jnanaraja (1503), Ganesa (1507) and Vallala (1510)[12] European traders and scholars visiting India in the sixteenth and seventeenth centuries witnessed this last flicker of astronomical work It was this information that attracted eminent European scholars in the eighteenth century

The axe of fanaticism again fell in 1669 when the last of the Great Moguls, Aurangzeb Alamgir, sacked Benares "to demolish all the schools and temples of the infidels and to put down their religious teaching and practice"

The origins of Benares observatory therefore are shrouded in obscurity It is known that Vallala moved to Benares for astronomical studies in about 1500 AD, which might account for the existence of an observatory there Sir Robert Barker was told in 1772 that the observatory was constructed on the orders of Emperor Akbar in the late sixteenth century A Campbell and T D Pearse, who visited the observatory in the 1770s stated that the observatory was built two centuries previously by Raja Man Singh son of Jai Singh, and named *Man Mandir* after him J L Williams and William Hunter, who visited India in 1793 and 1798 respectively, on the basis of a newly discovered document, *zeej Muhammadshahi*, the authenticity of which is questionable, considered that the observatory was built in 1743 "for the repose of holy men and pilgrims never used, nor capable of being used for any nice observations (that it was) built more for ostentation than the promotion of useful knowledge" G R Kaye (whose observations are considered incorrect by some authorities) in "A guide to the old observatories", published in 1920, concurred with the opinions of Williams and Hunter, surmising that the Benares observatory was one of the five Jantar Mantars (observatory) erected by Raja Jai Singh of Amber in 1737, the four others being built at Delhi, Ajmer, Ujjain, and Mathura[12] Prinsep and Tavernier who visited India in the seventeenth century, during the lifetime of another Raja, Jai Singh, considered that he had built the observatory[4]

All the above sources—those who believe that the observatory was built in the sixteenth or the seventeenth century or those who believe that the observatory was built in the eighteenth century—nevertheless agree that it was constructed on the roof of an old building It is hard to conjecture why anybody would wish to construct new observatory on the roof of an old building, or why that particular building was chosen for the placement of astronomical instruments It is obvious that Emperor Akbar, Raja Man Singh or Raja Jai Singh (whoever he might have been, as there were several of them), were interested in restoring a historical observatory rather than building a new one If they wanted to build a new observatory, and that particular building in Benares had no value, they would have done so, as they certainly did not lack the financial resources, closer to their capitals, rather than selecting an old damaged building, that too in Benares The above considerations including the fact that there has been a tradition of continued astronomical research in India going back to the ancient Vedic period leads to the conclusion that there was an observatory in Benares which was damaged during Shihabuddin's invasion of 1194 Whatever remained of the observatory was of interest to Indian astronomers who carried on limited observations there, and were seeking a patron to restore and renovate it When political normality returned in the sixteenth century, the old observatory was restored If the stories of Jai Chands are true, this again underlines the fact that the observatory was damaged and rebuilt several times, which attests to the historical significance of Benares as an ancient city of astronomical learning John Call, FRS, while looking at the signs of the zodiac on an ancient monument, observed "These buildings and temples were places of residence and worship of the original Bramins, and bear the mark of great antiquity, having perhaps been built before the Persian conquest," or, in the words of Barker, "it serves to strengthen the argument of supposing that the Bramins had a knowledge of astronomy before the introduction of Mahometanism into Hindostan (India)[2]

The meaning of *Man Mandir* is "Temple of the Mind," a more appropriate name for this ancient observatory This old observatory is purely of historic interest, as the methods of observation and the remaining instruments are of no value today Observations in the past were made with the naked eye using suitable devices for measuring the angles The telescope was unknown to Indian astronomers In spite of these limitations, some remarkable calculations were made in ancient India that led to the establishment of an astronomical epoch The Indian astronomers established an epoch when the Sun, the Moon and all the planets were last present in zero longitude that was in 3102 BC The period from one such epoch to the next, according to Aryabhata (fifth century AD) is 1,080,000 yr and is called a Yuga Four Yugas, the Krtayuga, Tretayuga, Dvaparayuga, and Kaliyuga make a Mahayuga, and 1,008 yugas make a kalpa The current quarter is the Kaliyuga, assumed to have begun at sunrise at lanka (a hypothetical place where the meridians of Ujjain intersect the equator) on Friday, February 18, 3102 BC The epoch of zero longitude is apparently useful in computing the mean longitude of a planet[13]

$$\text{mean longitude} = (R \times A)/C$$

where R is the number of revolutions of the planets in a yuga, C is the number of days in a yuga, and A is ahargana, that is the number of days elapsed since the epoch It is interesting to recall that the Newminster manuscript stated that the era of the flood was 3102 BC, the beginning of the kaliyuga era[14]

It was this type of information that impressed Professor John Playfair (1748-1819) to observe "Undoubtedly the ancient astronomers must have possessed the best instruments probably differing from modern ones, but fully as powerful "[4] The writers of the *Encyclopaedia Britannica* commented that the establishment of an astronomical epoch by the Hindoos (same as Hindus, Bramins, Indians) and the observation of this rare phenomenon—the conjunction of Sun, Moon and all the planets according to their mean positions—was a remarkable finding that had received respectable sanction by the French Academy of Sciences[6]

It is also curious that the date of Copernicus' birth, February 19, coincides with the date of the establishment of the astronomical epoch by the Hindus (Bramins), February 18, 3102 BC

Rotation of the Italian Peninsula

W. Lowrie & W. Alvarez

Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York 10964

Palaeomagnetic measurements of Upper Cretaceous–Palaeogene limestones from the northern Apennines indicate that the entire crust of the Italian Peninsula has rotated anticlockwise through 43° This is the first direct evidence from Italy of rotation, which is of comparable magnitude to rotations observed elsewhere in western Europe

ANTICLOCKWISE rotations of the Iberian peninsula[1], Sardinia[2], Corsica[3], and the western[4] and southern[5-7] Alps have been inferred from palaeomagnetic studies of Permian to mid Tertiary rocks and from geological evidence[8] An anticlockwise rotation of the Italian peninsula has also been suggested The rotation of Italy fits some theoretical schemes of Mediterranean palaeogeography These include originally continuous, linear, E–W mountain belts[9] and microplates packed into the western apex of the Tethys embayment of Pangea[10] Evidence of rotation has been found in palaeocurrent directions in the Tertiary Apennine flysch[11], and from palaeomagnetic measurements in the southern Alps (Permian and Triassic)[5,6] and the southern Alpine foothills (Tertiary)[12]

Palaeomagnetic studies in the southern Alpine region cannot, however, be used as evidence for rotation of the Italian peninsula, because the two areas are separated by the Po Basin in which the base of the Pliocene is as much as 6,000 m below sea level[13] (twice the present depth of the western Mediterranean basins) These sediments have been strongly folded and faulted, indicating severe tectonic activity Nothing is known of the pre-Miocene tectonic history of the Po basin, thus it cannot be assumed that evidence from the southern Alps is applicable to the Italian peninsula

No previous palaeomagnetic studies have been carried out in the Italian peninsula A major difficulty is that the western part of the peninsula is predominantly covered by allochthonous sequences, and the autochthonous (?) eastern sequences contain no strongly magnetic rocks We here describe the results of palaeomagnetic studies on a weakly magnetic Upper Cretaceous–Palaeogene limestone formation in the autochthonous or

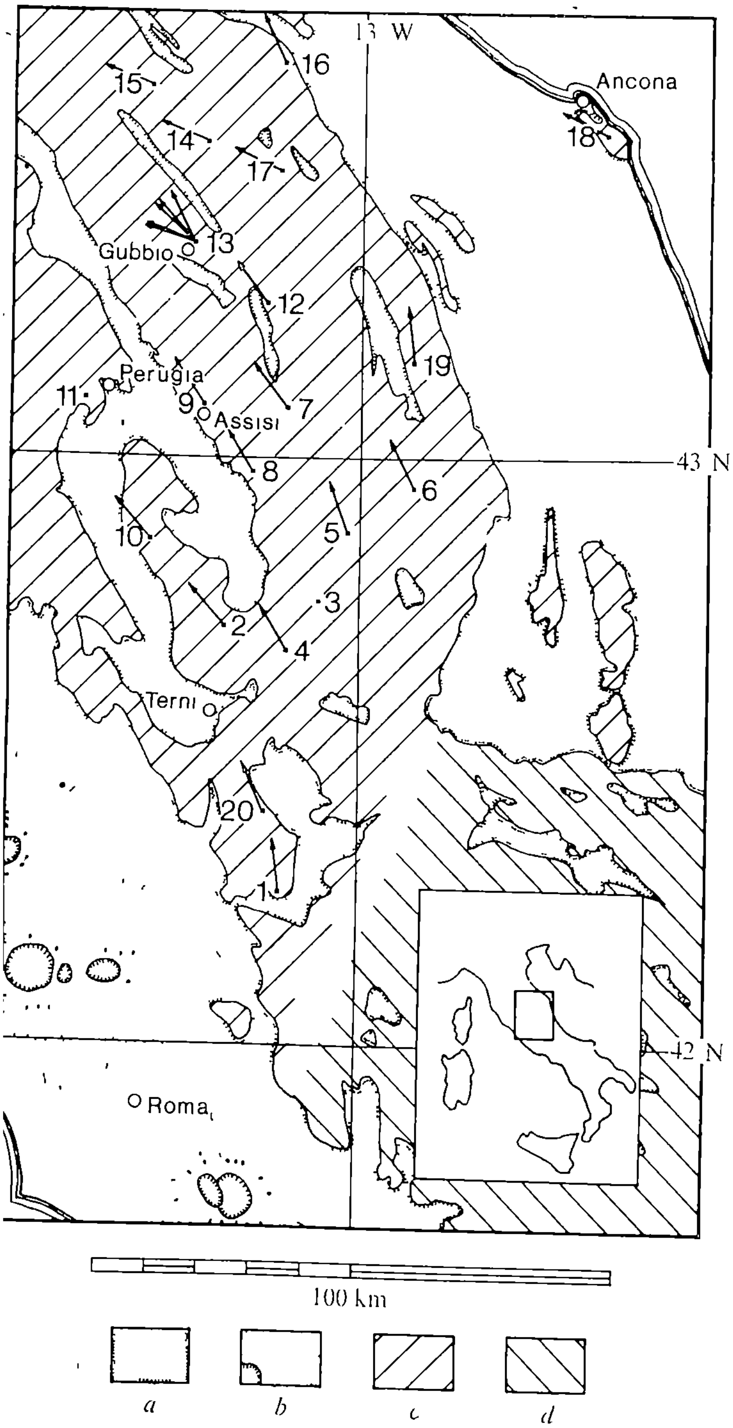

Fig 1 Location of sample sites, arrows show declination of remanent magnetisation *a*, Upper Tertiary–Quaternary sedimentary cover, *b*, Quaternary volcanic centres, *c*, Umbrian sequence (Mesozoic–Lower Tertiary), *d*, Abruzzi sequence (Mesozoic–Lower Tertiary)

para-autochthonous Umbrian sequence of the northern Apennines.

A neritic carbonate platform which occupied the area of the miogeosynclinal Umbrian sequence during the early Liassic subsequently broke up into a complex of seamounts and basins and underwent pelagic sedimentation during the remainder of the Jurassic and Cretaceous[14]. Increasingly terrigenous sedimentation in the Palaeogene led to the deposition of Miocene turbidite flysch, and to tectonic deformation in the late Miocene, the Pliocene and the Quaternary[15]. A long interval (Upper Cretaceous–Middle Eocene) is represented by the Scaglia Rossa, a pelagic limestone. Frequent outcrops and quarries expose this attractive stone. The time interval spanned by the formation, and its age and probably autochthonous character make it suitable for palaeomagnetic sampling.

Twenty different localities were sampled (Fig. 1). At locality 13 (the classic profile of the Bottaccione gorge at Gubbio[16,17]) the entire section is exposed, and we placed five sites here at different stratigraphic levels in order to measure the variation in palaeomagnetic directions during the depositional interval. Twenty-four sites were sampled. At each site, 7 to 14 oriented cores were drilled—a total of 180 cores, each of which gave two or three one-inch cylindrical specimens. The remanent magnetisations were very weak—10^{-6} to 10^{-7} gauss—but could be measured with very good repeatability. Susceptibilities were also very low—10^{-6} to 10^{-5} gauss oersted^{-1}.

A representative specimen was selected from each site and subjected to progressive alternating field (AF) demagnetisation in peak fields of up to 400 oersted in intensity. The demagnetisation characteristics were uniform for all the specimens (Fig. 2). After initial removal of an unstable component of magnetisation, the remanent intensity and direction were quite stable throughout the remainder of the demagnetising range, occasionally acquiring an anhysteretic component in 400 oersted. Computer analysis of the demagnetisation curves, utilising one index for directional stability and a separate index for overall magnetisation stability[18] enabled us to select the optimum demagnetisation field for each site. As the optimum field was always less than 200 oersted, all of the specimens were demagnetised in fields of 100 oersted and 200 oersted. Statistical analysis of the remanent directions for each site at each demagnetisation stage gave within-site circles of confidence with an average radius (α_{95}) of 10.7°.

The palaeomagnetic data were satisfactory at all but two of the sites. Local structural and stratigraphical complications obscured the significance of the data from site 3. At site 11, half of the sample directions were closely grouped near the mean normal directions of the other sites, but the other half had normal declinations and negative inclinations. It is possible that a partial field reversal was recorded in these samples. Alternatively, some of the samples may have been accidentally inverted. Because of these ambiguities the data from sites 3 and 11 were excluded from this preliminary analysis.

At site 13A a field reversal was apparently recorded. Most of the samples had normal directions, the remainder were exactly reversed in both inclination and declination. The normal equivalent directions were used in computing the site mean and other statistics.

Evidence from the five sites within locality 13 shows a progressive change in direction. The older sites, lower in the section, have more westerly declinations (by about 35°) than the younger sites. If supported by more detailed study, this implies that some rotation occurred during the mid Cretaceous–mid Eocene. Palaeontological dating of individual sites is at present available in only a few instances. These are in agreement with the established stratigraphy. Further palaeontological work is in progress and hopefully will enable us to refine the present picture.

The pink colour of the limestone at first suggested that secondary components of magnetisation resulting from haematisation may be important. Several tests indicated that this was not the case.

At site 9, samples were taken from adjacent pink and white sections of the same bed. Both sets of samples gave good quality data, similar in intensity, and with well grouped, reversed directions of magnetisation that did not differ significantly from each other. From this we conclude that the pink pigment does not provide an important contribution to the total remanence of the Scaglia Rossa. Thermal demagnetisation of pilot specimens from each site showed a notable decrease in the intensity and increased dispersion of the directions of weak remanence in the temperature range 550–600° C. These results suggest that the dominant magnetic mineral is probably magnetite, although the presence of a haematite phase cannot be completely discounted. Precise determination of the magnetic mineralogy is complicated by the difficulty of separating the magnetic minerals. Preliminary results indicate, however, that stable, secondary chemical remanent magnetisation is unlikely to be a serious factor affecting the remanent directions of the Scaglia Rossa.

The site mean directions of the remanence after alternating field demagnetisation in 200 oersted are shown in Fig. 3, the reversed directions were used in statistical analysis and in the calculation of the mean direction. The distribution of azimuths was uniform about the mean direction, and the distribution of angular differences from the mean direction was Fisherian at the 90% confidence level. The mean declination and inclination of the Scaglia Rossa were 320.1° and 45.4°, respectively, with $\alpha_{95}=5.9°$.

The mean locations of the late Cretaceous and early Tertiary poles for stable western Europe and the Russian platform are 83°N 194°E, and 75°N 161°E, respectively[19], the mean of these poles is at 79°N 178°E. The corresponding direction of site declinations are shown in Fig. 1. All but two of the sites were normally magnetised, the normal equivalents of the magnetisation at the centre of our sampling area would have a declination of 4.5° and an inclination of +52°.

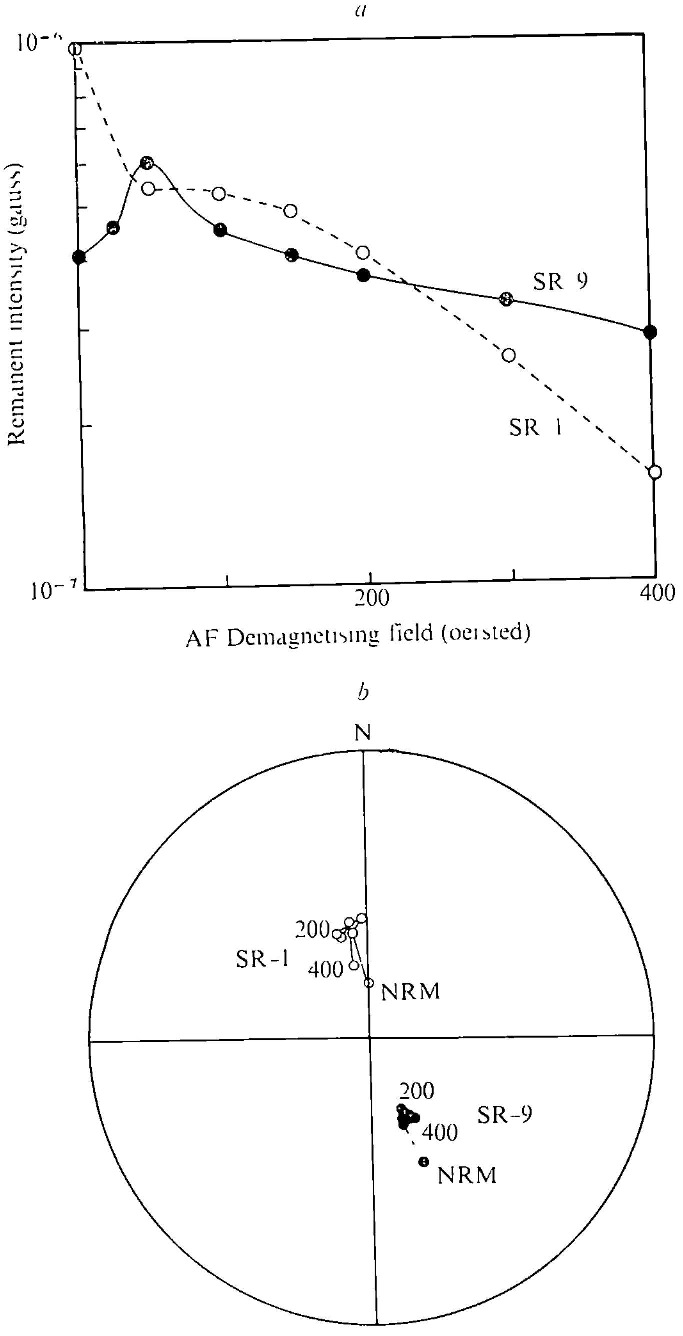

Fig. 2 Intensity (*a*) and direction (*b*) variations of normal (SR-1) and reversed (SR-9) specimens during alternating field (AF) demagnetisation. NRM, Natural remanent magnetisation.

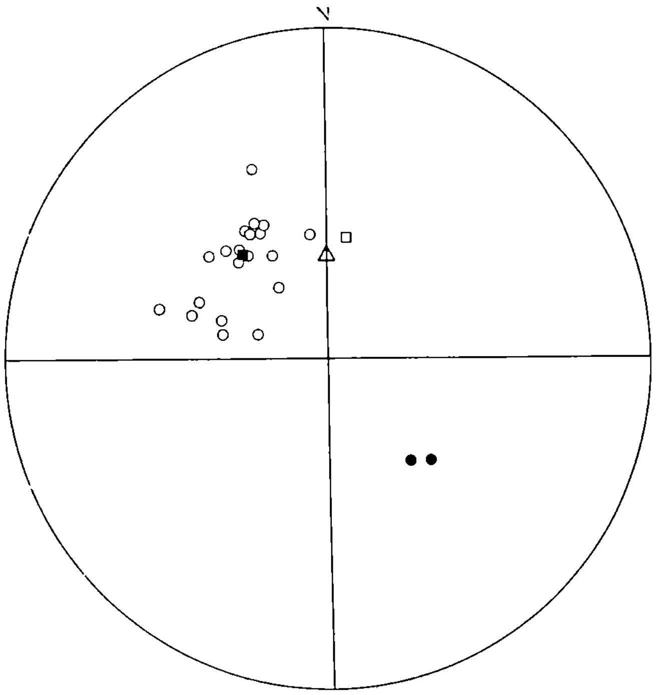

Fig. 3 Stereogram showing site mean directions of remanent magnetisation of the Scaglia Rossa after AF demagnetisation in 200 oersted. Open (solid) circles, normal (reversed) directions, open square and triangle, directions of the early Tertiary and Cretaceous (respectively) geomagnetic fields derived from the appropriate mean pole positions for stable Europe, solid square, mean direction for the Scaglia Rossa.

That direction differs by 6° in inclination and 43° in declination from the mean direction of our data. Thus, the inclinations are not significantly different and we cannot determine a palaeolatitude change with respect to stable Europe. There is, however, a significant declination difference, which is uniform at all but a few of the most northerly sites (Fig. 1).

The Scaglia Rossa carries a remanence which is probably not affected to any serious extent by secondary magnetisation. The relatively slow pelagic deposition, the long time interval represented by the formation, and the magnitude of the declination difference, show that this difference cannot be a result of secular variation. We therefore conclude that the rocks of the Scaglia Rossa have been physically rotated about a sub-vertical axis.

We envisage three ways in which such rotation could occur. First, there could have been rotation of the Mesozoic–Cainozoic sedimentary cover as a whole, relative to the underlying crust, if the cover is allochthonous above a major *decollement* surface. This, however, would require a relative displacement of about 100 km between the northern and southern parts of the studied area, nowhere have horizontal displacements of more than a few kilometres been observed. Second, the same rotational effect could be produced by simultaneous, independent, *en echelon* rotations of a series of small, allochthonous structures. Although we cannot dismiss this possibility, there is no evidence for it and this tectonic style has never been suggested for the Umbrian Apennines. Third, the entire crust of the Italian Peninsula may have rotated. This interpretation seems to be more compatible with the geological evidence than either of the others.

The 43° counterclockwise rotation is in the same sense as, and is of comparable magnitude to, rotations observed in other parts of the western Mediterranean. This is the first direct evidence that the Italian Peninsula fits this pattern.

A more detailed understanding of the tectonic significance of the rotation will emerge from additional palaeontological and palaeomagnetic sampling and measurement. It should be possible to determine whether deposition of the Scaglia Rossa occurred during the rotation, as suggested by the palaeomagnetic data from the five sites at locality 13 It should also be possible to test the hypothesis of oroclinal bending as the origin of curvature of the northern Apennines These studies are still in progress and a complete report will be presented later

We thank Drs A Jacobacci, E Centamore and M Valletta of the Servizio Geologico d'Italia for advice in the field and Drs I W D Dalziel, N D Opdyke and R Larson for discussion This work was supported by the National Science Foundation

Bovine satellite I DNA consists of repetitive units 1,400 base pairs in length

Michael R. Botchan

Cold Spring Harbor Laboratory, PO Box 100, Cold Spring Harbor, New York 11724

Bovine satellite I DNA was shown by its susceptibility to cleavage by restriction endonucleases to consist of direct tandem repeats 1,400 base pairs in length Renaturation kinetics indicate that this repeat is itself internally repetitious These data argue in favour of a DNA replication mechanism for the evolution of this satellite

THROUGH the light microscope, mitotic chromosomes look highly organised This organisation is revealed by means of the various cytochemical techniques that show characteristic banding patterns for each metaphase chromosome[1] Although the molecular basis of these bands is still unknown, it seems clear[2,4] that the local variations in staining intensity seen with a particular dye are a consequence of differences in packing density of the unit chromosomal fibre Regions selectively stained darker by Giemsa are shown to have a higher concentration of packed DNA than other chromosomal regions when measured by phase contrast microscopy[3,4] and by Feulgen staining[4,5] In many organisms, the regions adjacent to the centromeres of the chromosomes can be easily identified by these techniques Several authors have suggested that the dense packing of the chromosomal DNA in this area is due to the regularity of the DNA itself[4,6,7] The long order organisation of these units is therefore of interest

Wherever tested, the DNA of this centromeric heterochromatin[8,9] is largely composed of sequences of nucleotides repeated many times Because these sequences are simple and tandemly arranged, they can often be separated as 'satellites' from the bulk of the DNA by a variety of equilibrium centrifugation techniques Two approaches have been taken to study the organisation of satellite DNA First, using renaturation kinetics, Waring and Britten[10] found that mouse satellite renatured with a $C_0t\ \frac{1}{2}$ of 7×10^{-4} mol 1^{-1} s This renaturation data indicated a statistical complexity of 200-300 base pairs for the mouse satellite DNA, and similar data have been obtained for other satellite DNAs The second experimental approach to satellite organisation has been through various sequencing techniques The pyrimidine tract analysis of Southern[11] indicated that the guinea pig satellite α, contained a large amount of a repeating hexanucleotide Superficially, these results seem to be at odds with the observed kinetics of renaturation of satellite α DNA But Southern's data also showed that only 30% of the guinea pig α satellite was composed of the hexanucleotide and that the remaining sequences were considerably more complex It also seemed likely that the bulk of the DNA in this satellite was related to the basic unit by simple mutations and rearrangements Further studies indicate a similar situation in the mouse[12] and kangaroo rat[13] satellites The most complete sequencing data exist for the *Drosophila virilis* group satellites Gall and Atherton[14] have found that more than 93% of this satellite is of one heptamer A resolution between the two approaches discussed has not been reached, although it seems clear that the renaturation complexity cannot be taken as an actual repeat length

The data from all of these studies do not bear on the existence of a long range order to repeats within satellites Consider a tandem array where the repeat unit is (*baaaaaa* *b*) where both *b* and *a* represent a small sequence The renaturation rate of such a DNA would be dominated by *a* and would not indicate a higher order repeat Sequencing experiments without long overlapping fragments from this array might also leave this large repeat undetected This problem can potentially be resolved by use of restriction enzymes, which cleave double-stranded DNA at specific sequences If each repeat unit contains a single restriction sequence in it, the whole array of repeats will be cut to the length of one unit If the sequences of type *b* contain a restriction sequence, but those of type *a* do not, long fragments will be generated which reflect the separation between *b*s, that is the long order repeat If the site occurs more than once, fragments will be generated, the molecular weights of which will add up to the repeat length

Britten and Smith[15] have determined that 10% of bovine DNA consists of "highly repetitive" sequences, furthermore, this genome contains four distinct classes of satellite DNA[16,17] Kurnit *et al*[16] have found that the four satellites are located on the autosomal chromosomes and in the region of centromeric heterochromatin The major satellite[16–19], which has been mounted on an oriented platform. To obtain a long exposure on Her X-1 and also the background counting rate, the telescope was inclined at 17° to the zenith and programmed to point due north for 7 min and 8° east of north for the following 7 min; this cycle of orientation was continued throughout the flight. In-flight calibration of the detectors was carried out with a ^{241}Am source. Pulse heights in the energy range 21 to 125 keV were sorted into 15 energy channels and telemetered, together with aspect information. The time of occurrence of each event was recorded with an accuracy of 1 ms.

The procedure for evaluating the efficiencies as a function of time, and the reduction of spectral data, have already been described (ref. 1 and references therein). In the energy range 21.5 to 81.7 keV a total of 11,561 ± 1,122 excess counts attributable to Her X-1 were recorded in a total exposure of 5.7×10^5 cm^2 s. The spectral data and our earlier results are plotted in Fig. 1. The fluxes observed in the March experiment are about a factor of two lower than the fluxes observed in the December experiment. The December data can be fitted with either a power law with an exponent −2.7 or with a thermal spectrum characterised by a kT of 23 keV. The March results could be fitted with a power law of exponent −2.3 or a thermal spectrum with a kT of 30 keV. Combining the satellite observations below 20 keV and other balloon observations (Fig. 2) we find that a plasma temperature of 23 keV ($T = 2.7 \times 10^8$ K) fits reasonably well the entire data over an energy range 2 to 80 keV. The scatter in Fig. 2 arises because the observations were made at different phases of the binary and 35-d cycles. One significant feature is the steep fall in the intensity beyond 80 keV. Such a steepening was also reported by Ulmer *et al*[2,3]. The anomalously high value of Sharma *et al*[4] for intensities in the energy band 80 to 100 keV is not supported by our observations. If the intensity was really high it should have been seen with high statistical significance in our experiment. There is some evidence in the present experiment for variations in intensity in the 20 to 60 keV band by a factor of about two within the time scale of observation of ~70 m.

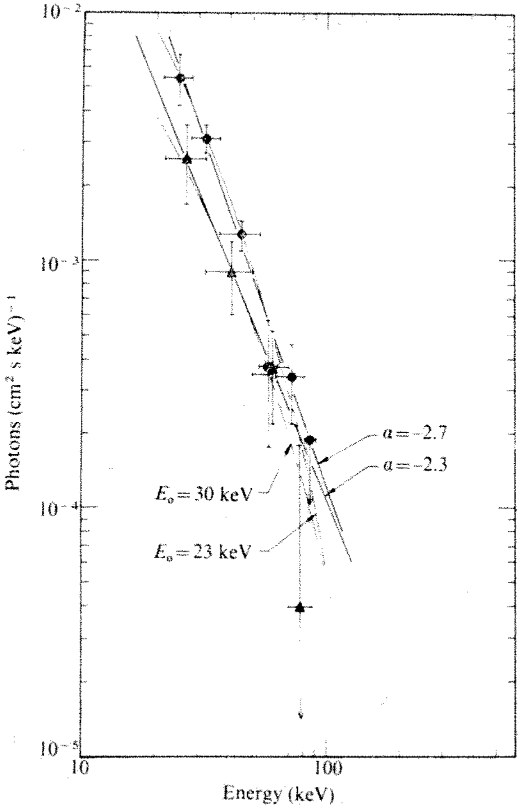

Fig. 1 Energy spectrum of Her X-1 in the hard X-ray band 20 to 90 keV measured in the experiments of March 9, 1973 and December 12, 1973. Best fits for power law (E^{α}) and plasma temperature (kT) for each of the two sets are also shown. ▲, March 9 (ref. 1); ●, December 12 (present work).

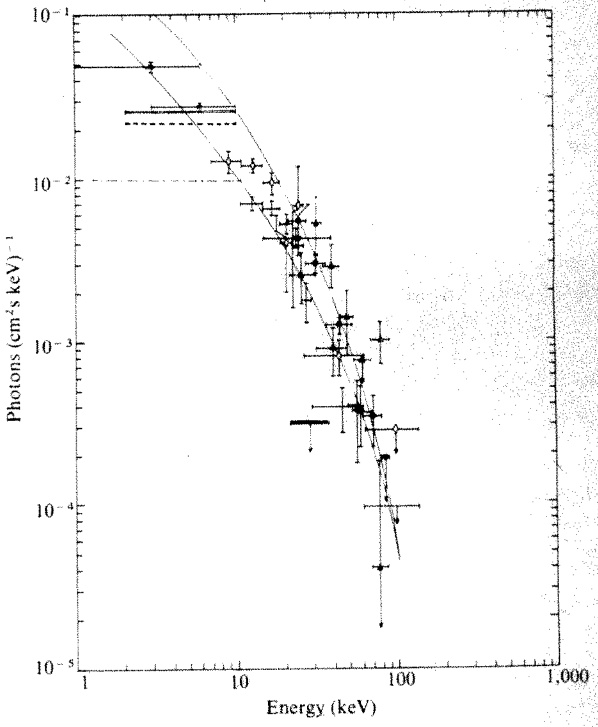

Fig. 2 Data on the energy spectrum of Her X-1 in the 1 to 100 keV interval, together with the fit for plasma temperature kT 23 to 30 keV as derived from our observations. Diamond and +, Refs 2, 3; —, Uhuru [5,6]; ▲, ref. 1; △, ref. 4; ×, ref. 9; ●, present work. Pulsation: – –, Uhuru; – · – · – ·, ref. 7; —↓, our work.

In our experiment the source 3U1706+32 did have a considerable exposure when observations on Her X-1 were made. But the intensity of the source in the 2 to 6 keV band is 1/25 that of Her X-1 (ref. 5) and even if the spectrum is flat, the contribution in the 20 to 45 keV will be small compared with that of Her X-1.

Since most of the contribution from Her X-1 was recorded in the energy channel 21.5 to 45.2 keV, the timing data in this interval were analysed to find the fraction of the pulsating component. The data were cast into 20 phase bins and none of the phase histograms with periodicity ranging from 1,235 to 1241 ms revealed a peak larger than 2.5σ. The χ^2 was as low as nine for 19 degrees of freedom (95% confidence). The data were also analysed in shorter time stretches of ~10 min each, and no significant peaks were seen in this analysis. These observations lead to an upper limit of 10% for the pulsating component if the width of the pulse is less than 400 ms. The limit is about the same even if the pulse width is as short as 60 ms. The data was also subjected to a Fourier analysis using an FFT algorithm; the power density distribution (Fig. 3) does not reveal any appreciable power in any of the frequencies investigated. In view of the negative results the algorithm was further tested by analysing self-generated data modulated with a known frequency.

The present upper limit of 10% for the pulsating component in the 20 to 45 keV band is to be compared with the lower limit of 80% in the 2 to 6 keV band[6] and 60% in the 2 to 11 keV band[7]. Ulmer *et al.*[2] have remarked that their preliminary analysis of the OSO-7 data failed to reveal any pulsations in the 7 to 60 keV band but further analysis may allow them to detect pulsations. Kurfess and Crosa[8] found no pulsed emission at energies greater than 100 keV, and could set a 2σ upper limit of 3.4×10^{-3} photons cm^{-2} s^{-1} in the 0.1 to 10 MeV range assuming a duty cycle of 35%.

So there is no evidence for a pulsating component at energies greater than 20 keV. As shown earlier the spectrum of the

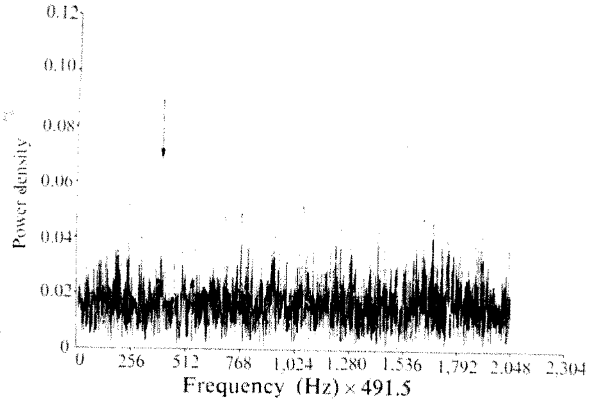

Fig. 3 Power density spectrum up to 2,048 Hz as obtained in the Fourier analysis of ~492 s of observation in the range 21.5 to 45.2 keV. The frequency corresponding to 1.24 s is shown by an arrow.

total X-ray emission over the entire energy range 2 to 80 keV can be fitted with a single plasma temperature of $kT = 23$ to 30 keV. The behaviour of the pulsating component as a function of energy is also shown in Fig. 2.

The possibility that the hard X rays arise from a different object close to Her X-1 can be ruled out from evidence[8,9] of the binary modulation and the 35-d cycle variation for the hard X-ray emission in phase with the modulation at lower energies.

The models which have been proposed to explain the features in the 2 to 10 keV range, regard Her X-1 as a rotating magnetised neutron star accreting matter from an eclipsing companion of larger size[10-14]. The influx of matter is constrained to a narrow region around the magnetic poles. The X-ray emission results from the transformation of the kinetic energy of the infalling matter into radiation which emerges preferentially in directions almost normal to the direction of the inflow. The observation of pulsed emission with the frequency of rotation is then a consequence of the direction of the magnetic axis being different from the rotation axis. The detailed pulse profile and in particular the pulse width, is determined by the angle between the two axes, the emission pattern and the direction of viewing. In such a model, if the hard X rays (20 to 80 keV) also originate from the same region as X rays of lower energy (1 to 10 keV) the pulsating fraction can be different only if the fan beam in hard X rays is considerably broader so as to reduce the extent of modulation during rotation. This, however, is contrary to the prediction of Davidson's accretion model[14] according to which the harder X rays come from a relatively narrow band at the base of the accretion funnel resulting in a narrower pulse width than in the X rays of 2 to 10 keV. Thus the present observations point to the need of a second component of X rays apart from the pulsating part.

We thank Professor L. E. Peterson for discussions.

Direct observation of rock macerates

IN scanning electron microscopical (SEM) investigations of Precambrian sedimentary rocks, the risk of contamination during the preparation of rock macerates is extremely high. The technique described here and the use of stringent controls, have reduced to a minimum the degree of contamination by dust and microorganisms and, during preparation, enabled the recognition of artefacts from laboratory reagents.

In a preliminary study we used a dark, laminated, shaly sandstone from the Diabaig Formation of the Torridon Group, in north-western Scotland[1] (NG799605)[2]. This formation is believed to be older than $995 \pm 24 \times 10^6$ yr (ref. 3), and was selected because samples from other outcrops of this formation have already yielded microfossils[4-6].

Samples of rock were powdered with a hammer on a clean steel block and the powder was passed through a 600-μm sieve. Working in a sterile air flow, small samples of the powder were put into purpose-built wax stub tubes[7] in stoppered plastic test tubes, and treated with Schulzes' solution for 3 h to oxidise any exposed organic matter. Tests on spores of *Penicillium chrysogenum* showed that they were destroyed after only 30 min treatment; 3 h was, therefore, considered long enough to clean the

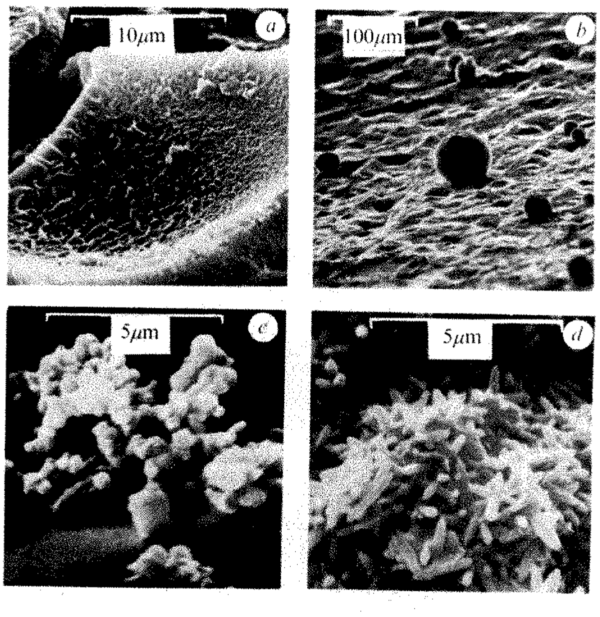

Fig. 1 *a*, Ornamented crust from the evaporation of laboratory distilled water; *b*, resin spheres from de-ionised water; *c*, residue after the reaction of hydrofluoric acid with silica; *d*, precipitated metal fluorides from a prepared rock macerate.

sample. The samples were short centrifuged and washed until free of acid, and were then treated with 38–40% hydrofluoric acid for 6 h, centrifuging down the residues and changing the acid every 2 h. The final residues were short centrifuged and washed until free of acid, and the stub tubes were left to dry overnight in a clean vacuum desiccator. The following day, the residues were prepared[7] for SEM observations. Control preparations of all reagents were examined by SEM, revealing many artefacts (Fig. 1*a–c*). Laboratory distilled water was evaporated to form an ornamented crust (Fig. 1*a*), and de-ionised water carried over microspheres of resin (Fig. 1*b*). So to wash the residues, glass distilled water was de-ionised and then distilled again in a still cleaned with chromic acid. To determine whether pure silica could produce organised microstructures after reaction with hydrofluoric acid, a silica glass test tube was sacrificed, and when treated in the same way as the rock, structures were produced (Fig. 1*c*).

Examination of rock residues in the SEM revealed considerable amounts of organic and mineral debris, together with organised microstructures. Figure 1*d* probably represents a precipitate of fluorides[8], and we believe the structures of Fig. 2*a–g* to be the remains of microorganisms, a judgement based on their superficial resemblance to extant genera of algae[9] and other described fossil forms[10]. We consider it unlikely that these structures were produced by inorganic precipitation or by recrystallisation.

We believe that these preparations are of technical interest in that they demonstrate the feasibility of using the SEM wax stub tube for micropalaeontological maceration when it is necessary to reduce contamination to a minimum. We have also found the stub tube invaluable in monitoring the artefact content of distilled water, and of active reagents such as hydrofluoric acid. Although we do not suggest that the stub tube should replace other mounting techniques in scanning electron microscopy, we submit that it can be a useful tool in the critical study of organic microfossils.

3,500-Myr-old granite in southern Africa

A GEOCHRONOLOGICAL study of the margin between the Rhodesian Craton and the Limpopo Belt in southern Africa has yielded the first conclusive evidence for the preservation of very old crustal material on the Rhodesian Craton. An age of 3,520±260 Myr has been obtained from a seven-point Rb–Sr whole rock isochron for samples of the Mushandike Granite, which intrudes tonalite gneisses near Fort Victoria (30° 50′E, 20° 04′S) in south-eastern Rhodesia. Its relation to the Bulawayan Group of the Victoria Schist Belt is uncertain. The possible presence of an intrusive contact of the granite within these rocks points out the need for a re-examination of the evidence for the widely accepted maximum age for the Bulawayan of 3,300–3,400 Myr (ref. 1).

The Mushandike Granite and its contacts with surrounding rocks have been described by Wilson[2,3]. For the most part, the 'granite' is a medium grained, massive granodiorite. It has undergone shearing and faulting since emplacement; the effects of that are especially intense in the southern and western parts, whereas in the northern and central parts little or no deformation has occurred. Evidence that the Mushandike Granite intrudes the Tonalite Gneiss Complex is strong. Wilson[2,3] reported xenoliths, typical of the

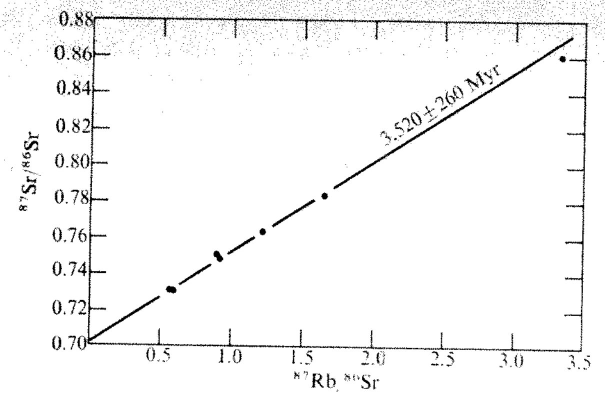

Fig. 1 Rb–Sr whole rock isochron for the Mushandike Granite.

surrounding gneisses, both in the centre of the granite and along its northern margin. In the north and south-east, the granite forms a lit-par-lit contact zone with the Gneiss Complex. Banding in the gneisses is roughly parallel to the contact along both margins, but tongues of granite cut across the banding in the north[3].

Along the southern margin of the granite, phyllites and amphibolites, assigned to the Bulawayan Group of the Victoria Schist Belt[2,3], occur. Shearing and faulting have obscured the original nature of the contact. Wilson[2,3] considers the granite to be post-Bulawayan. A narrow tongue of deformed granite, which can be traced into recognisable Mushandike Granite, occurs in the schist belt, suggesting an intrusive relationship. In one location the contract cuts across the trend of the phyllites. The occurrence of randomly oriented andalusite in the phyllites, and of cordierite and anthophyllite in the amphibolite, could be a result of contact metamorphism by the granite. Without a better understanding of the effects of the intense deformation in the contact zone, this evidence cannot be taken as conclusive; the present contacts could all be tectonic.

The Rb–Sr whole rock isochron (λ $^{87}Rb = 1.39 \times 10^{-11}$ yr^{-1}) for the Mushandike Granite, gives an age of 3,520 ± 260 Myr (Fig. 1); the analytical data are shown in Table 1. The seven analysed samples are all from the centre of the granite, away from the effects of deformation. There is evidence of some geological error in the data, and the quoted error in the age is that given by the isochron calculations McIntyre II and York I (ref. 4). Errors are quoted at the 95% confidence level.

Table 1 Analytical data

No.	Rb (p.p.m.)	Sr (p.p.m.)	$^{87}Rb/^{86}Sr$	$^{87}Sr/^{76}Sr$
1	71.8	354	0.587	0.7307
2	69.2	340	0.590	0.7305
3	65.5	209	0.907	0.7504
4	86.3	268	0.934	0.7487
5	63.9	151	1.22	0.7635
6	111	194	1.65	0.7840
7	107	93.9	3.32	0.8611

The calculated age is important in establishing conclusively the preservation of ancient crustal material on the Rhodesian Craton. It supports the findings of Robertson[5] who, on the basis of a detailed study of Rhodesian leads, postulated a ~3,500 Myr event on the Rhodesian Craton. He suggested that the event was associated with the formation of granitic crustal segments as well as with pre-Bulawayan lavas.

On the basis of field relationships, the Tonalite Gneiss Complex must be older than the Mushandike Granite. Preliminary isotope data for tonalite gneisses from the town of Fort Victoria, 10–15 km to the east suggest, however, that they may not record a significantly older isotopic age. The points do not define an isochron, showing considerable scatter, but they show no systematic deviation relative to the Mushandike Granite isochron. That may mean that correlations in the Gneiss Complex cannot be made over the distance involved, or that the intrusion of the Mushandike Granite was part of a widespread event which overprinted any isotopic record of the early history of the gneisses in the area. It is also possible that the emplacement of large bodies of granite north and south of the Victoria Schist Belt about 2,650 Myr ago[1] may have caused some isotopic mixing in the Fort Victoria gneisses at that time.

The ambiguity of the contact between the Bulawayan Group of the Victoria Schist Belt and the Mushandike Granite points out the need for reliable and precise age determinations on material from the schist belts themselves and on granitic bodies which have reasonably clear relationships to the schist belts. The ambiguous nature of the Mushandike–Bulawayan contact and uncertainty in the available, relevant age data mean that the age of the Bulawayan is now in question. The work of Robertson[5] suggests that most of the volcanics assigned to the Bulawayan Group are younger than 3,500 Myr, because leads recording a ~3,500 Myr event are generally restricted to pre-Bulawayan rocks. Three K–Ar determinations on muscovite from the pre-Bulawayan Que-Que Granite, about 160 km north north-west of Fort Victoria (29° 48′E, 18° 53′S) have given an age of 3,300–3,400 Myr (ref. 1). Although this clearly needs to be confirmed by other dating methods, it has, in the absence of other data, been widely accepted as an approximate maximum age for the Bulawayan.

Elsewhere in southern Africa, rocks older than 3,000 Myr have been found in the Barberton Mountain Land of the Kaapvaal Craton[6]. Of particular interest here is the new evidence, from Rb–Sr analysis of mineral fractions, that basalts of the Lower Onverwacht Group have an age of 3,500 ± 200 Myr. These rocks have been correlated with pre-Bulawayan volcanics on the Rhodesian Craton[7]. The Ancient Tonalite Gneisses which intrude the Lower Onverwacht have a Rb–Sr whole rock age of 3,440 ± 300 Myr (ref. 8).

No definite conclusions about the Rhodesian Craton can be drawn on the basis of Kaapvaal Craton age data. Chronological equivalence cannot be inferred from lithostratographic correlations between cratons, or even between different regions of a single craton. Until further work is done on Rhodesian material, the chronology of the Bulawayan Group remains uncertain.

Thermal model for origin of granitic batholiths

THE origin of granitic batholiths has been reviewed in the light of our understanding of the processes operative at destructive plate margins[1]. The thermal patterns at island arcs suggest that significant amounts of thermal energy must be released within downgoing oceanic plates, and that this energy may be transferred to the surface behind island arcs. In these regions heat flow values are abnormally high and andesitic volcanism is present. The high heat flow may be produced because the normal geothermal gradient is enhanced by penetrative convection of magmatic material which is derived from the downgoing plate. Many large granitic batholiths, such as those in Chile, are localised at plate margins, and some authors have proposed that the Sierra Nevada batholith originated in a similar setting along the continental margin in the downwarped portion of the lower crust. Dickenson[2] suggested that the magma for the batholiths was produced by partial melting within the downgoing plate, and was subsequently emplaced into the overlying continental crust. Bateman and Dodge[3], and Brown[1] suggested that emplacement into the lower crust, of andesitic material derived from the mantle, causes partial melting of crustal material, with the mixed product forming the magma for the granitic batholiths.

Experimental studies of the generation of granitic melts[4,5] from metamorphic rocks have shown that melts of granitic composition will occur under conditions of crustal pressure at temperatures of about 700–750° C provided that water is released by dehydration reactions. A granitic melt may be produced by partial melting of the crust at depths of 25–30 km, whereas granodiorites and diorites may be derived from partial melting at higher temperatures (800–950° C) and deeper crustal levels (30–45 km)[1]. At the continental margins where the crust is 40–50 km thick, the radioactive content and the thermal conductivity of crustal rocks, together with the heat flow values, suggest that the lower crust is at a temperature of around 700° C, although higher temperatures may be achieved locally, adjacent to mantle-derived magma. Using thermal considerations I have investigated the extent of partial melting in sialic crust adjacent to a deep seated intrusion.

The thermal effects which a magma induces in country rocks are considered first. The cooling of a magmatic body that is assumed to be instantaneously emplaced may be expressed by the time-dependent equation for heat transport in one dimension:

$$K(\delta^2 T/\delta Z^2) = \rho c_p(\delta T/\delta t) \qquad (1)$$

where K is the thermal conductivity, ρ is the density, and c_p is the specific heat. Solutions to the equation extended to handle partial melting, can be approximated by finite difference techniques: the governing difference equation solved for temperature is

$$T(Z, t+\Delta t) = [1 - 2K\Delta t/\rho c_p(\Delta Z)^2]\,T(Z,t) + K\Delta t/\rho c_p(\Delta Z)^2$$
$$[T(Z-\Delta Z, t) + T(Z+\Delta Z, t)] \qquad (2)$$

where $T(Z, t+\Delta t)$ is the temperature at time $t+\Delta t$ at a location Z; Δt is the time increment; and ΔZ is the distance increment. The finite difference approximation of the heat conduction equation for two different media, country rock and magma, requires that the respective values of ρ, K and c_p for each medium are used in equation (2). A boundary layer equation is then adapted for the contact between country rock and magma.

I have modified the numerical techniques to handle partial melting. Partial melting is typically an endothermic process, and the total amount of heat of fusion, H, necessary to melt a material is a function of the rock composition. The total melting of basalt may absorb 400 calorie g^{-1}, and 10% partial melting may absorb, proportionately, 40 calorie g^{-1}. The latent heat of fusion of rocks of granitic composition is about 50 calorie g^{-1} (ref. 6). Thus, if it is assumed that a metamorphic rock is composed of 50% granitic material with the other 50% of mafic composition, to melt the granitic fraction of this rock would require a minimum of 25 calorie g^{-1}. It can be assumed that H is absorbed linearly over a range of melting, or as assumed here, the melting process can be simulated by absorption of H at a constant temperature, similar to the melting of a single component chemical species. Although the melting of a metamorphic rock is probably more complicated, that assumption is probably a reasonable description of the fusion process[7].

If a point, Z, reaches the temperature of melting, TM, it absorbs heat according to the equation

$$\Delta H = c_p \Delta T$$
$$\text{where } \Delta T = T(Z, t+\Delta t) - TM. \qquad (3)$$

The temperature of the point, Z, is TM until the total heat of fusion, H, has been absorbed. Once H is absorbed, the point responds according to equation (2). The absorbed heat will be released—equation (3)—as the temperature falls to TM and solidification begins; the heat of solidification is assumed to be equal to H. Conservation of energy is maintained throughout the process.

A simple geological model may best illustrate the effect of partial melting in country rocks adjacent to a magmatic body in the lower crust. The following parameters are used: $TM = 700°$ C; ρm (density of magma) $= 2.7$ g cm^{-3}; ρc (den-

Table 1 Partial melt zones around emplaced magma

Width of magma (km)	Initial temperature of country rock (° C)	TM of country rock (° C)	H (calorie g^{-1})	Total width (both sides) of zone of partial melting (km)
2	500	700	50	0.8

6	600	800	50	2.2
10	500	700	50	4.0

sity of country rock) = 3.3 g cm^{-3}; Km = 0.01 calorie cm^{-1} s^{-1}; Kc = 0.007 calorie cm^{-1} s^{-1}; T_m = 1,200° C (temperature of magma); H = 50 calorie g^{-1}; m = magma; c = country rock. Consider a slab shaped magma, 4 km thick, emplaced into a lower crust with an original uniform temperature of 500° C. It is likely that a mafic magma of this size, and a viscosity of 10^6 poise, will convect naturally[8]. One of the effects of convection within the magma will be to raise the temperatures in the country rocks above the maximum which would have been achieved if the magma was cooling without convection (Table 1). It is assumed that the temperature distribution within a freely convecting magma will be governed by the adiabatic law so that the temperature may vary with depth by anything from 0.3 to 1° C km^{-1}. Therefore the change in temperature from the top to the bottom of a convecting body 4 km thick will be only 2° to 4° C. The temperature distribution within and outside the magma at different times, for one half of a symmetrical model, is shown in Fig. 1. The temperatures reflect the heat (H = 50 calorie g^{-1}) which is absorbed in the country rock as a result of melting once the melting temperature, TM (700° C) has been reached. After 40,000 yr, 0.8 km of country rock would be partially melted and the total partial melt zone on both sides of the magma chamber would be 1.6 km wide.

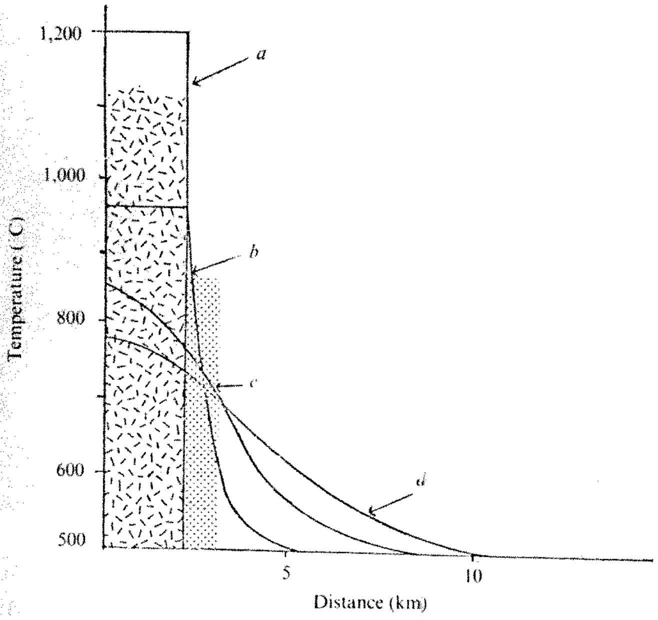

Fig. 1 The temperatures around a symmetrical magma 4 km thick: *a*, at emplacement; *b*, after 2 × 10^4 yr; *c*, after 10^5 yr; *d*, after 2 × 10^5 yr. Stippled area is the zone of partial melting. TM = 700° C; H = 50 calorie g^{-1}; initial temperature of the magma = 1,200° C. At T_m = 900° C convection ceases and the magma cools by conduction.

As most magmas derived from the mantle will have properties that do not vary greatly from those assumed here, the size of the partially melted zone around an intrusive will be principally a function of the thickness of the intrusive and of the initial temperature and composition of the country rock. Table 1 shows the width of zones of partial melting for several different examples. In each of these examples the parameters had the values already given here, and except in the cases specified in Table 1, convection within the magma was assumed.

Using H = 50 calorie g^{-1}, a magma 6 km thick intruded into country rock which is at 600° C, would partially melt a zone 2.6 km thick on each side. Within the zone of partial melting the amount of liquid granitic melt is a direct function of the original composition of the metamorphic rock. Thus, for example, with a metamorphic rock which was originally 50% granitic and 50% mafic, the zone of partial melt may be 50% liquid. A slab of magma 6 km thick, emplaced into country rock which is at 400° C, would have a zone of partial melting with a total combined width on both sides, of 1.8 km. If a magma were emplaced into a metamorphic rock of mafic composition with little granitic fraction, the width of the zone of partial melting would be reduced. This can be illustrated by taking H equal to 100 calorie g^{-1} instead of 50 calorie g^{-1}. The width of the zone of partial melting is reduced from 3.0 to 2.4 km thick (Table 1), but the amount of partial melting is still substantial. For a case in which the country rock has a higher temperature of melting (TM = 800° C) and a larger heat of fusion (H = 100 calorie g^{-1}) than the magma, the total width of the zone of partial melting on both sides of the magma would be only 1.0 km. As these properties may be more similar to a mafic metamorphic rock, the partial melting of metamorphic rock around a magma is probably limited. These results (Table 1) indicate that large portions of country rock with some fraction of granitic composition, can be melted under less extreme crustal conditions, and magma convection greatly increases the extent of partial melting in country rocks. Similar quantities of magma will produce, however, little melt in the upper crust (300° C).

If a substantial proportion of the zone of partial melting is liquid, then that liquid may mix with the magma. The amount of physical mixing between magma and country rock is partly dependent upon the relationship between the amount of time it takes the magma to solidify, and the time during which the country rock is melted. At the outer front of the zone of partial melting the country rock may still be melting after the mafic has cooled below its temperature of solidification. As long as the magma is above the solidus, however, the zone of partial melting in the country rock could mix with the magma and thus alter its composition. As an example, it can be assumed that solidification of the magma occurs at 900° C. Then an intrusive 6 km thick within country rock which had an original temperature of 500° C, will solidify after about 92,000 yr (Fig. 2). By that time the country rock would be partially melted out to 1.2 km from the contact, and most of the melt could mix with the magma before it solidified. If only a portion of the country rock melted, then limited amounts of granitic melt above and below the contact would be available for mixing. The refractory country rock material that does not melt may fall to the floor of the magma or be incorporated within it. In this manner the original magma could be diluted with both fused granitic material and refractory country rock.

The extent of partial melting around a slab shaped magma emplaced into a crust with a moderate geothermal gradient, is

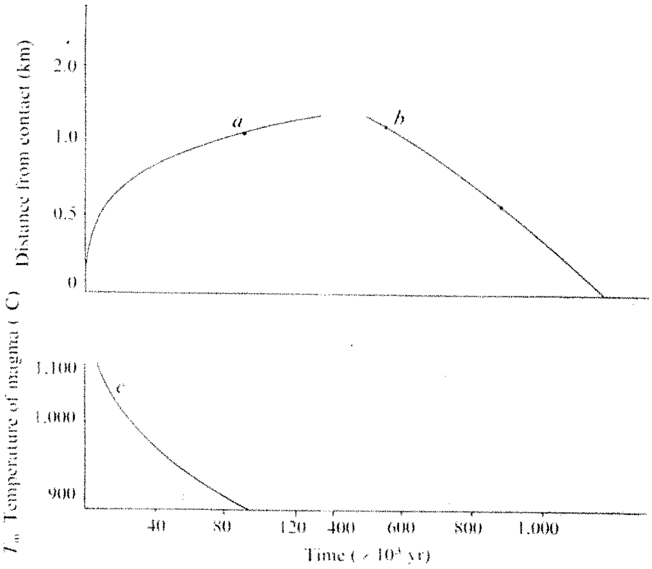

Fig. 2 *a*, The time which elapses between emplacement of magma and the onset of partial melting at increasing distances from the contact; *b*, the time which elapses between emplacement and the onset of solidification in the zone of partial melting at varying distances from the contact; *c*, the rate of cooling of a convecting magma.

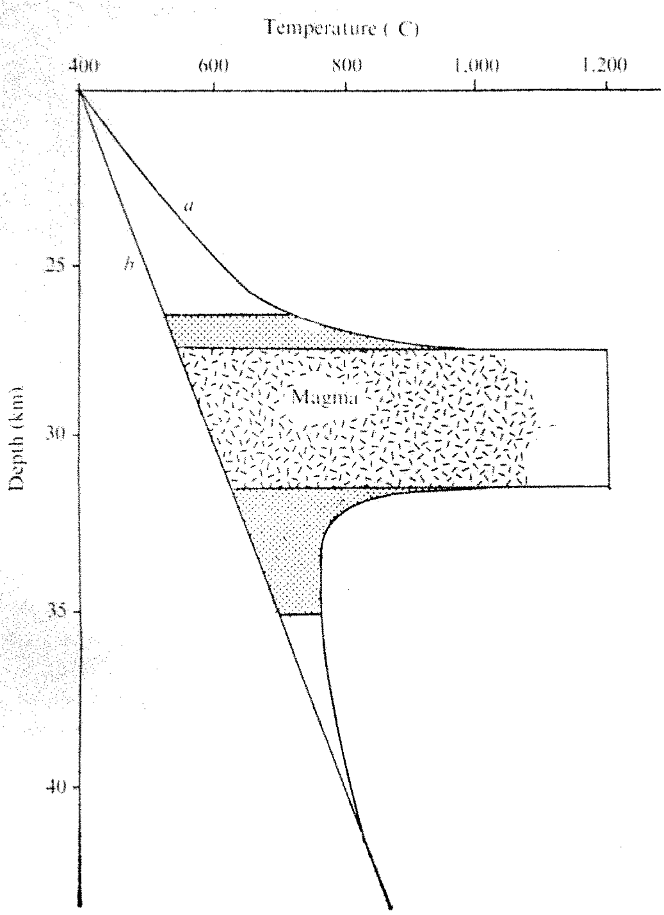

Fig. 3 Temperatures around an intrusive which is 4 km thick, and centred on a depth of 30 km: *a*, maximum temperatures; *b*, geothermal gradient; stippling, zone of partial melting. Initial temperature of magma = 1,200° C; H_f = 50 calorie g^{-1}.

significantly different from that indicated by the model in Fig. 1. An asymmetrical orientation of the heat fluxing from the top and the bottom of the magma is produced. Taking an initial geothermal gradient of 20° C km^{-1}, and a magma slab 4 km thick emplaced at 30 km depth, the country rock temperatures below the magma would be at least 80° C more than above the magma, and those temperatures would increase with depth (Fig. 3). In this thermal model the values of the parameter given already define the initial boundary conditions, and crustal rocks initially hotter than 700° C (35 km depth) are assumed not to undergo partial melting. The maximum temperatures achieved in the country rock in a case such as that are shown in Fig. 3. About 1 km of country rock above the upper contact, and about 4 km below the magma, would undergo partial melting. The total width of the zone of partial melting would exceed the initial thickness of the magma. In that case, the total heat flux from the top of the magma would be about twice that from the bottom. As much as 5 km of the country rock would have been melted partially, whereas in the model shown in Fig. 1, the partially melted zone is only 1.6 km thick adjacent to a slab of magma of the same size, with initial country rock temperatures of 500° C.

The process of partial melting and solidification of the country rock adjacent to an intrusive, takes approximately 2×10^5 yr in the cases discussed. Solidification of the mafic parent rocks at 900° C takes about 10^4–10^5 yr. Thus, the zones of partial melting adjacent to a magma may have a higher mobility for a considerably longer period of time than either the solidified magma or the lower crustal material that has not undergone partial melting. These zones of partial melting may serve as sites for the emplacement of other material derived from the mantle, and further partial melting in the lower crust may follow.

These thermal models suggest that there are a number of possible ways in which an intermediate rock type could be derived from the mixing of a mantle derived parent with partially melted lower crustal rocks that are adjacent to the intrusion. Dense refractory material in the zone of partial melt, as well as in the parent magma, will tend to sink and lighter granitic fractions will tend to migrate upward. Granitic material may be formed from the partial melt zones above and below the magma and from differentiation of the original magma. These lighter granitic liquids could accumulate into large magmas in the lower crust and then migrate and collect to form plutons of batholithic proportions in the upper crust. In this two stage model of the origin of granitic batholiths along continental margins, the production of the intermediate granitic rocks may be intimately associated with the production and migration of magmas of andesitic to basaltic composition from active subduction zones at the continental margins.

Thermal contraction joints in a spreading seafloor as origin of fracture zones

If newly formed oceanic crust is moving away from a spreading axis, it can be expected to contract by cooling. Vertically, the cooling is expressed in the existence and cross-sectional shape of the mid ocean ridges, where there is a relationship between depth of the ocean and age of the crust[1]. A steady state solution for a model of a lithospheric plate which cools while moving[2–4] is compatible with data on topographical height.

Horizontally, in the direction of spreading, cooling will result in the formation of superficial horst and graben structures parallel to the median rift[5,6]. Also in the third direction—that of the ridge axis—internal stresses will arise which are much larger than the breaking strength of rock. If the thermal expansion coefficient λ, is 1.5×10^{-5} ° C^{-1}, and Young's modulus, *E*, is 1×10^6 kg cm^{-2}, a decrease in temperature of 1,000° C gives an internal tension of 15,000 kg cm^{-2}. Faulting can therefore be expected to occur perpendicular to the direction of the ridge axis, and I propose that fracture zones are the topographical expression of those faults (Fig. 1 and refs 7–10).

The hypothesis provides a model for an orthogonal median rift–fracture zone system[11]. The actual shape of the ridge as a whole will be dictated by other causes, such as the shape of the initial rift. That is exemplified by the parting of North America and South America from Africa. A change in spreading direction can also place constraints on the shape of the ridge. Straight ridges with fracture zones and no offset could be explained using this model:

the thermal contraction character is primary, and the transform fault function[13] is secondary.

Additional evidence of thermal contraction in the direction of the ridge axis comes from the distribution of fracture zones in the central North Atlantic and the equatorial Atlantic. There, the Mid-Atlantic Ridge is far from straight. The active sections of the fracture zones do not obey strictly the small circle pattern dictated by purely geometric or kinematic considerations[14]. The departures from that pattern are significant and apparently systematic (Fig. 2). Fracture zones and median rift segments still form an orthogonal system but the pattern as a whole becomes fanned, following to some degree the bends of the ridge.

The segments of the median rift and the fracture zones therefore form a complex dovetail construction, interlocking opposing lithospheric plates. Thus, in order to free the plates, about 6% of shortening in the direction of the ridge axis is needed. That is of the right order of magnitude compared with the maximum depth of the ocean, which in these parts varies between 5.5 and 6 km. That would lead to a total vertical contraction of 3–6%, depending on the thickness assumed for the lithosphere.

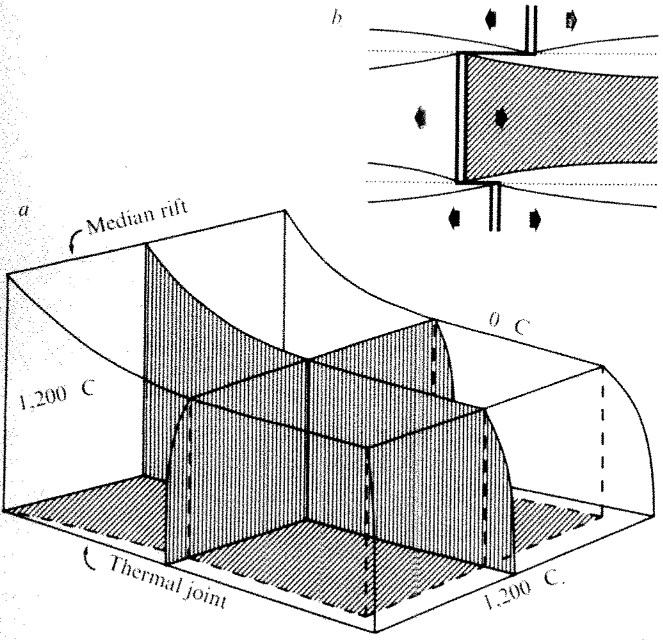

Fig. 1 *a*, Seafloor spreading implies cooling of newly formed lithosphere. A plate moving from the median rift will contract as shown. Thermal joints develop at right angles to the ridge axis. *b*, Plan view of thermal joints accommodating transform faults; arrows indicate spreading directions.

The fanning of fracture zones can be understood by considering the mechanism which makes the plates move. Thinking in terms of gravitational sliding, the analogy to glacier flow[15] may be extended by comparing the 'bights' of the Mid-Atlantic Ridge to a firn or névé: the shape of the bights would determine the flow pattern of the lithosphere which slides passively downwards to both sides, coagulating into rigid plates in which the stress trajectories are roughly parallel to the fossil fracture zones and to the growth lines of the lithosphere, that is, the magnetic lineations. The stress trajectories would then converge off the concave sides of the ridge, thus accounting for the fanning. A pull, exerted by the sinking lithosphere in the subduction zones and/or by a friction exerted by the upper mantle at the base of the lithosphere may be added to this. If the latter effect were dominant, however, fanning still occurs because the ridge represents a curvilinear zone of weakness in the lithosphere. A zone such as this (with a lower Young's modulus) in an elastic plate under tension would be reflected in the stress distribution. Experiments with a sheet of pararubber have shown that the longer axes of the strain ellipsoids are deflected towards the normal to the weakened zone.

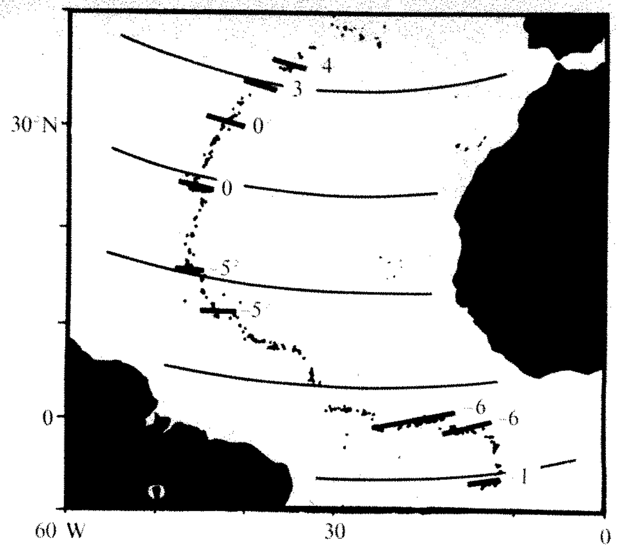

Fig. 2 Departure of fracture zone azimuths from a small circle pattern with a pole spreading at 63°N and 27°W.

Once the pattern has been established and the fracture zones begin to function as transform faults, the stress distribution will be affected if some form of welding occurs along the plane of the fracture zone. Extrapolation of the results of the experiments with pararubber, indicates that the larger principal stress may be expected to become deflected towards the normal to the fracture zone, thus releasing the normal stress in the plane of the fracture zone, and easing the movement.

The observation that fracture zones may be fanning implies that, although statistically and on a global scale the small circle concept[14,16] remains valid, poles derived from individual fracture zones or from a number of close fracture zones do not necessarily represent the true spreading pole. True spreading poles can only be found by averaging weighted azimuths of all of the fracture zones in a given area. The degree of fanning is also a function of age, with the fanning reaching its maximum at the ridge axis. The present data on the central North and equatorial Atlantic do not yet allow a final analysis.

called satellite I, has been estimated to be 6–7% of the total DNA[16,17]. Here I report studies with restriction endonucleases which show that this satellite DNA has a repeat unit which is 1,400 (± 50) bases long. This higher order repeat unit which accounts for more than 95% of the satellite is internally repetitious.

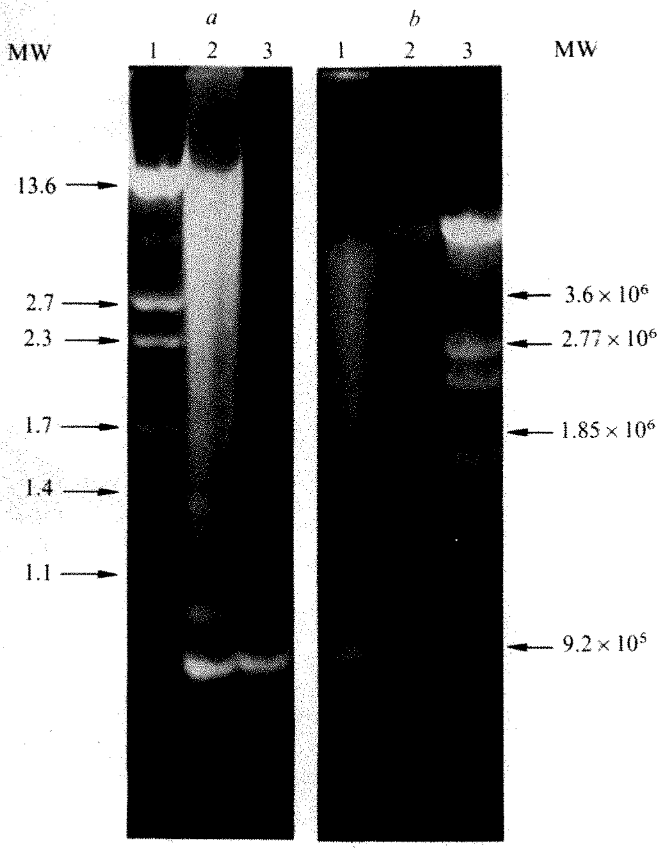

Fig. 1 *a*, Endonuclease EcoRI cleavage of total and satellite I bovine DNA. Bovine kidney cells (MDBK) were grown in Dulbecco's media containing 10% calf serum, and 5 μCi ml^{-1} of ^{32}P as orthophosphate. Confluent monolayers of cells were collected and the DNA extracted as described previously[35]. Cells were lysed in 0.5% SDS and subjected to a pronase (1 mg ml^{-1}) digestion for 8 h in 0.01 M Tris *p*H 7.9 + 0.001 M EDTA. The lysate was extracted with phenol and chloroform-isoamyl-alcohol (24:1 v/v) and then dialysed extensively. After digestion with RNase (100 μg ml^{-1}) and redigestion with pronase, the DNA was re-extracted with phenol. The DNA was then dialysed into 0.01 M Tris *p*H 7.9 + 0.001 M EDTA. The DNA extracted by this procedure had a specific activity of 19,700 c.p.m. μg^{-1}. 100 μg of total DNA was placed in a 5 ml solution of CsCl (density 1.700 g ml^{-1}) and centrifuged for 48 h at 50,000 r.p.m. and then 20 h at 40,000 r.p.m. Fractions corresponding to satellite I DNA were pooled and dialysed into 0.005 M $Na_2B_4O_7$ + 0.005 M Na_2SO_4 *p*H 8.9. $AgNO_3$ was added to an f of 0.40 and the solution brought to a density of 1.500 g ml^{-1} with Cs_2SO_4. The satellite DNA was again banded in this solution by centrifugation as described above. The fractions of the major peak (corresponding to 80% of the DNA in the gradient) were pooled. (1) 2 μg of Ad2 virus DNA, (2) 2 μg total bovine DNA, (3) 1 μg satellite I DNA were digested separately for 2 h in 0.01 M Tris *p*H 7.9 + 0.01 M $MgCl_2$ at 37° C, with EcoRI. The volume of the reaction mixture was 100 ml and contained 0.03 mg ml^{-1} of the restriction enzyme. The enzyme was isolated as described[21,22,36]. The reaction mixtures were adjusted to 20% sucrose and layered onto a 1.5% agarose slab gel. After electrophoresis in E buffer[22,36] at 5 V cm^{-1} for 10 h, the DNA in the gel was stained with ethidium bromide (0.5 μg ml^{-1}). The gel was photographed with ultraviolet excitation of ethidium fluorescence[36]. The molecular weights correspond to the Ad2 fragments A–F shown in (1)[22]. *b*, Partial digestion of satellite I DNA with EcoRI. 1 μg of high molecular weight satellite I DNA was digested with EcoRI as described in Fig. 1*a*, but the reaction was stopped after 20 min by adjusting the mixture to 0.01 M EDTA and 0.5% SDS. The reaction mixture was then subjected to electrophoresis as before. The partial digestion is in position (2). (1) is the total bovine DNA digested to completion and (3) is the Ad2 markers. The molecular weights shown refer to the partial cleavage products.

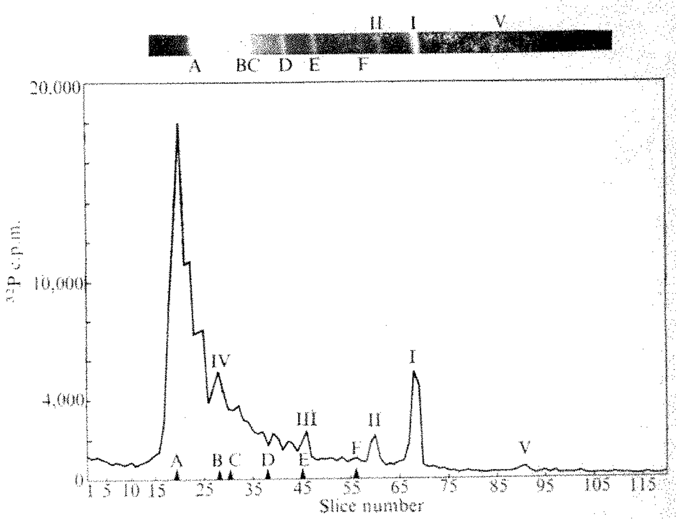

Fig. 2 Distribution of fragment sizes of total bovine DNA after digestion with EcoRI. 7.5 μg of ^{32}P-labelled bovine DNA (specific activity 1.9 × 10^4 c.p.m. μg^{-1}) + 0.3 μg ^3H Ad2 DNA (specific activity 10^6 μg^{-1}) were digested with EcoRI as described in Fig. 1. The reaction was stopped with 0.5% SDS + 0.01 M EDTA and extracted once with phenol. The DNA fragments were precipitated with ethanol and resuspended in 50 μl of one quarter XE buffer. The sample was layered on to a 0.5 cm × 12 cm cylindrical gel of 0.7% agarose–2.2% acrylamide[36] and electrophoresed for 12 h at 50 V. The gel was stained and photographed as in Fig. 1. The gel was sliced into 1 mm sections and each fraction placed into 3 ml of Aquasol (New England Nuclear). The slices were soaked overnight and counted. Arrows refer to peak positions of the Ad2 DNA markers. The amount of DNA in each peak I–V is given in the text and is the average of five such measurements.

Restriction endonuclease cleavage

Bovine kidney cells were grown in tissue culture and the total DNA was labelled and extracted as is described in the legend to Fig. 1. The DNA thus extracted was of high molecular weight as the mean sedimentation coefficient as measured by centrifugation in a neutral sucrose gradient was 60S. Satellite I DNA has a density of 1.716 g ml^{-1} (refs 16, 17) in neutral CsCl and was isolated from the bulk of the DNA, which has a mean density in CsCl of 1.700, by both Ag^+–Cs_2SO_4 and CsCl equilibrium centrifugation techniques[16–19]. After the isolation of this satellite, the DNA was digested to completion with the restriction enzyme EcoRI (see ref. 20 for nomenclature of restriction enzymes), which cleaves DNA at the sequence

$$\begin{matrix} \downarrow \\ {}^{5'}\mathrm{GAATTC}^{3'} \\ {}^{3'}\mathrm{CTTAAG}^{5'} \\ \uparrow \end{matrix}$$

(ref. 21). The products of this digestion were then analysed by electrophoresis through 1.4% agarose gels. Figure 1*a* is a photograph of a slab gel after electrophoresis and staining of the DNA with ethidium bromide and it illustrates that the material migrates in one discrete band. More than 95% of the radioactivity in satellite I DNA is recovered in this band. The molecular weight of this band of DNA was calculated to be 9.2 × 10^5 (± 6%), from its relative mobility to the EcoRI fragments of adenovirus 2 DNA[22] (Fig. 1). The molecular weight of EcoRI cleaved satellite I DNA indicates that within this DNA at points every 1,400 base pairs is the sequence $\frac{\mathrm{GAATTC}}{\mathrm{CTTAAG}}$. A partial digestion of the satellite DNA confirms the tandem nature of this repeat. If the enzyme digestion is stopped before completion, multiple bands of DNA are seen after electrophoresis whose molecular weights form an arithmetical progression (Fig. 1*b*). The monomer,

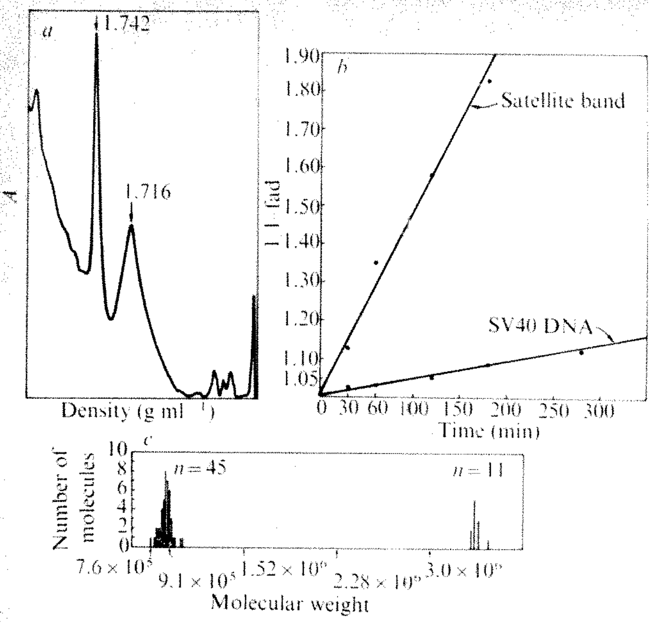

Fig. 3 Physical characterisation of satellite I DNA. *a*, Total bovine ^{32}P DNA was digested with EcoRI and electrophoresed as in Fig. 2. Fractions corresponding to peak I (fractions 66–69) were pooled and the DNA eluted by electrophoresis as described in refs 35 and 36. 0.5 μg of this DNA was centrifuged to equilibrium in CsCl at 44,000 r.p.m. in a Spinco Model E centrifuge. A densitometer trace of the *A* profile is shown. The density of 1.716 g ml^{-1} was calculated relative to SPOI DNA $\rho = 1.742$ g ml^{-1} using $1/\beta = 8.4 \times 10^{-10}$ c.g.s. units. *b* Renaturation kinetics of this ^{32}P satellite DNA were measured relative to ^{3}H-SV40 DNA by hydroxylapatite chromatography (Bio-Rad HTP) fad = fraction of DNA binding to HAP as double strands. 0.2 μg of the ^{32}P satellite DNA (specific activity 11,000 c.p.m. μg^{-1}) plus 0.42 μg of ^{3}H- SV40 DNA (40,000 c.p.m. μg^{-1}) were combined in 100 ml of 0.001 M Tris *p*H 7.9 + 0.025 M NaCl. 50 μl of 1 M NaOH were added and the solution boiled in a sealed capillary tube for 25 min to fragment the DNA. The solution was then neutralised with 50 μl of 1 M HCl and brought to 2.2 ml with 0.035 M phosphate buffer + 0.4% SDS. 0.5 ml were taken at the specified times and the fraction of molecules that were double-stranded was measured by chromatography at 60° C. Total eluants from the 0.14 M phosphate buffer and the 0.40 M phosphate buffer washes were precipitated separately with trichloroacetic acid and filtered on to Millipore HAWP filters. The ethanol washed filters were counted in Aquasol. The slopes of the lines differ by a factor of 11. Since the SV40 DNA is 2.1 times more concentrated than the satellite DNA, the kinetic rate constants differ by a factor of 23. *c*, Histogram of molecular weights of the EcoRI cleaved satellite I DNA: total high molecular weight satellite I DNA was digested with EcoRI as described in Fig. 1. The reaction mixture was extracted with phenol and the DNA precipitated with ethanol at −20° C. The precipitate was resuspended in 0.01 M Tris *p*H 8 buffer containing SV40 circular DNA. Molecular lengths were measured by electron microscopy as described in ref. 36. The lengths were converted to molecular weights by assigning a molecular weight of 3.4 × 10^{6} daltons for circular SV40 molecules.

dimer, trimer, tetramer and pentamer molecular weights of the 9.2 × 10^{5} dalton repeat were resolved.

The molecular weight of the EcoRI digested satellite DNA was measured by electron microscopy. A histogram of molecular weights is given in Fig. 3*c*. Assigning a molecular weight of 3.4 × 10^{6} for the circular SV40 DNA which was added as a marker, the EcoRI digested satellite had a molecular weight of 8.9 × 10^{5} (± 3%). There is then excellent agreement between the electron microscope and electrophoretic measurements of this repeat length.

Because satellite I DNA was cleaved to a uniform length by EcoRI, it seemed likely that cleavage with this restriction enzyme would provide a simple and quantitative procedure for the satellite isolation. The 1,400 base pair repeat in satellite I can indeed be detected in the EcoRI digestion products of the unfractionated total bovine DNA (Figs 1*a* and 2). When the total DNA is digested to completion with the endonuclease, a heterogeneous population of DNA molecules is obtained. Within this distribution one can clearly distinguish four bands of DNA, whose molecular weights are: 1.35 × 10^{6} (III); 10^{6} (II); 9.2 × 10^{5} (I); and 5.1 × 10^{5} (V) daltons (Fig. 1*a*). The source of the DNA did not influence these molecular weights as commercial calf thymus DNA (Worthington) yielded bands with DNA at identical molecular weights.

The amount of material in each of the bands was measured by digesting ^{32}P-labelled bovine DNA with EcoRI and analysing the fragments by electrophoresis. The distribution of ^{32}P-DNA, together with the positions of internal markers are shown in Fig. 2. The percentage of the total DNA under each band was calculated to be: 0.7% (IV), 0.5% (III), 1% (II), 6.7% (I), 0.1% (V) respectively for the peaks from highest to lowest molecular weight. The DNA from the peak labelled I was cut from a separate gel and eluted by electrophoresis. This DNA was identified as satellite I on the basis of the following criteria: (1) its buoyant density in a neutral CsCl gradient of 1.716 g ml^{-1} (see Fig. 3); (2) its relative amount in the genome of 6.7%; (3) its coelectrophoresis with EcoRI cleaved satellite I DNA; and (4) its renaturation kinetics being indistinguishable from that of satellite I (see below).

It is well known that the rate of reannealing of a unique sequence DNA is directly proportional to the complexity of the sequence[23,24]. Therefore, if the satellite I DNA were composed of a unique repeating unit 1,400 base pairs long, it should renature at a rate roughly four times faster than that of SV40 DNA, allowing for the fact that there is an 18% difference in G–C composition between the two DNAs. A comparison of the rates of renaturation of denatured SV40 DNA and denatured satellite I DNA is shown in Fig. 3*a*. The total kinetic complexity of the satellite as measured by renaturation kinetics is 200–250 base pairs. A complexity of 200 base pairs for the satellite I must mean that the 1,400 nucleotide repeat is internally repetitious. Based upon what is known about the structure of other satellites[11–14], a likely hypothesis is that the repeat unit has a short 8–20 base pair substructure with enough divergence in this basic sequence to cause an apparent complexity of 200–250 base pairs. The picture of this satellite then emerges as a repeating unit within a repeating unit. The EcoRI sequence repeat could be again part of a larger repeating unit containing the 1,400 base pair unit an integral number of times. In view of this, it was interesting to digest bovine satellite I DNA with another restriction enzyme.

At least two specific endonuclease activities can be isolated from *Haemophilus influenzae* serotype d. Hind II cleaves at the sequences

↓
$^{5'}$-GTPYPUAC-
-CAPUPYTA-$^{5'}$ (ref. 25). Hind III does not cleave satellite I
↑

(Fig. 4*b*). When high molecular weight satellite DNA is digested with Hind II or the combined enzymes, the DNA is degraded to two fragments of 7.4 × 10^{5} and 1.25 × 10^{5} daltons as measured by electrophoresis through 4% polyacrylamide gels (Fig. 4*a*). The same two bands can be seen in the Hind II + Hind III digest of total bovine DNA (Fig. 4*a*). The sum of the molecular weights of these two bands is 8.65 × 10^{5}. If the EcoRI repeat were part of a larger unit, two other enzymes might be expected to give fragments whose additive molecular weights indicated a greater complexity. There is a 3% difference between this estimate of the repeat length and the electron microscope length of the EcoRI repeat. A second enzyme system then indicates that there is a repeat unit every 1,400 base pairs within this satellite.

Restriction map of satellite

Within this repeat unit it is now possible to orient the EcoRI cleavage sequence and the two Hind II cleavage sites by comparing the products of digestion of the enzymes working
